STATA BASE REFERENCE MANUAL
RELEASE 12

A Stata Press Publication
StataCorp LP
College Station, Texas

Version 12

Published by Stata Press, 4905 Lakeway Drive, College Station, Texas 77845
Typeset in TEX
Printed in the United States of America

10 9 8 7 6 5 4 3 2 1

ISBN-10: 1-59718-098-X (volumes 1–4)
ISBN-10: 1-59718-099-8 (volume 1)
ISBN-10: 1-59718-100-5 (volume 2)
ISBN-10: 1-59718-101-3 (volume 3)
ISBN-10: 1-59718-102-1 (volume 4)
ISBN-13: 978-1-59718-098-6 (volumes 1–4)
ISBN-13: 978-1-59718-099-3 (volume 1)
ISBN-13: 978-1-59718-100-6 (volume 2)
ISBN-13: 978-1-59718-101-3 (volume 3)
ISBN-13: 978-1-59718-102-0 (volume 4)

Table of contents

intro . . . . . Introduction to base reference manual 1

about . . . . . Display information about your Stata 6
adoupdate . . . . . Update user-written ado-files 7
alpha . . . . . Compute interitem correlations (covariances) and Cronbach's alpha 11
ameans . . . . . Arithmetic, geometric, and harmonic means 18
anova . . . . . Analysis of variance and covariance 22
anova postestimation . . . . . Postestimation tools for anova 62
areg . . . . . Linear regression with a large dummy-variable set 78
areg postestimation . . . . . Postestimation tools for areg 84
asclogit . . . . . Alternative-specific conditional logit (McFadden's choice) model 86
asclogit postestimation . . . . . Postestimation tools for asclogit 96
asmprobit . . . . . Alternative-specific multinomial probit regression 103
asmprobit postestimation . . . . . Postestimation tools for asmprobit 127
asroprobit . . . . . Alternative-specific rank-ordered probit regression 137
asroprobit postestimation . . . . . Postestimation tools for asroprobit 149

BIC note . . . . . Calculating and interpreting BIC 157
binreg . . . . . Generalized linear models: Extensions to the binomial family 162
binreg postestimation . . . . . Postestimation tools for binreg 174
biprobit . . . . . Bivariate probit regression 178
biprobit postestimation . . . . . Postestimation tools for biprobit 185
bitest . . . . . Binomial probability test 188
bootstrap . . . . . Bootstrap sampling and estimation 193
bootstrap postestimation . . . . . Postestimation tools for bootstrap 215
boxcox . . . . . Box–Cox regression models 219
boxcox postestimation . . . . . Postestimation tools for boxcox 229
brier . . . . . Brier score decomposition 231
bsample . . . . . Sampling with replacement 237
bstat . . . . . Report bootstrap results 244

centile . . . . . Report centile and confidence interval 251
ci . . . . . Confidence intervals for means, proportions, and counts 257
clogit . . . . . Conditional (fixed-effects) logistic regression 269
clogit postestimation . . . . . Postestimation tools for clogit 285
cloglog . . . . . Complementary log-log regression 290
cloglog postestimation . . . . . Postestimation tools for cloglog 299
cnsreg . . . . . Constrained linear regression 302
cnsreg postestimation . . . . . Postestimation tools for cnsreg 308
constraint . . . . . Define and list constraints 311
contrast . . . . . Contrasts and linear hypothesis tests after estimation 314
contrast postestimation . . . . . Postestimation tools for contrast 377
copyright . . . . . Display copyright information 379
copyright boost . . . . . Boost copyright notification 380
copyright freetype . . . . . FreeType copyright notification 381
copyright icu . . . . . ICU copyright notification 384
copyright jagpdf . . . . . JagPDF copyright notification 385
copyright lapack . . . . . LAPACK copyright notification 386
copyright libpng . . . . . libpng copyright notification 387
copyright scintilla . . . . . Scintilla copyright notification 389
copyright ttf2pt1 . . . . . ttf2pt1 copyright notification 390

copyright zlib . . . . . zlib copyright notification 392
correlate . . . . . Correlations (covariances) of variables or coefficients 393
cumul . . . . . Cumulative distribution 401
cusum . . . . . Graph cumulative spectral distribution 405

db . . . . . Launch dialog 409
diagnostic plots . . . . . Distributional diagnostic plots 411
display . . . . . Substitute for a hand calculator 423
do . . . . . Execute commands from a file 424
doedit . . . . . Edit do-files and other text files 425
dotplot . . . . . Comparative scatterplots 426
dstdize . . . . . Direct and indirect standardization 433
dydx . . . . . Calculate numeric derivatives and integrals 452

eform_option . . . . . Displaying exponentiated coefficients 458
eivreg . . . . . Errors-in-variables regression 459
eivreg postestimation . . . . . Postestimation tools for eivreg 464
error messages . . . . . Error messages and return codes 466
estat . . . . . Postestimation statistics 467
estimates . . . . . Save and manipulate estimation results 475
estimates describe . . . . . Describe estimation results 479
estimates for . . . . . Repeat postestimation command across models 481
estimates notes . . . . . Add notes to estimation results 483
estimates replay . . . . . Redisplay estimation results 485
estimates save . . . . . Save and use estimation results 487
estimates stats . . . . . Model statistics 491
estimates store . . . . . Store and restore estimation results 493
estimates table . . . . . Compare estimation results 496
estimates title . . . . . Set title for estimation results 502
estimation options . . . . . Estimation options 503
exit . . . . . Exit Stata 506
exlogistic . . . . . Exact logistic regression 507
exlogistic postestimation . . . . . Postestimation tools for exlogistic 525
expoisson . . . . . Exact Poisson regression 529
expoisson postestimation . . . . . Postestimation tools for expoisson 541

fracpoly . . . . . Fractional polynomial regression 543
fracpoly postestimation . . . . . Postestimation tools for fracpoly 558
frontier . . . . . Stochastic frontier models 562
frontier postestimation . . . . . Postestimation tools for frontier 576
fvrevar . . . . . Factor-variables operator programming command 578
fvset . . . . . Declare factor-variable settings 581

gllamm . . . . . Generalized linear and latent mixed models 587
glm . . . . . Generalized linear models 589
glm postestimation . . . . . Postestimation tools for glm 623
glogit . . . . . Logit and probit regression for grouped data 629
glogit postestimation . . . . . Postestimation tools for glogit, gprobit, blogit, and bprobit 640
gmm . . . . . Generalized method of moments estimation 642
gmm postestimation . . . . . Postestimation tools for gmm 699
grmeanby . . . . . Graph means and medians by categorical variables 703

hausman . . . . . Hausman specification test 706

heckman . . . . . Heckman selection model 715
heckman postestimation . . . . . Postestimation tools for heckman 732
heckprob . . . . . Probit model with sample selection 738
heckprob postestimation . . . . . Postestimation tools for heckprob 746
help . . . . . Display online help 751
hetprob . . . . . Heteroskedastic probit model 753
hetprob postestimation . . . . . Postestimation tools for hetprob 760
histogram . . . . . Histograms for continuous and categorical variables 763
hsearch . . . . . Search help files 773

inequality . . . . . Inequality measures 777
intreg . . . . . Interval regression 780
intreg postestimation . . . . . Postestimation tools for intreg 790
ivprobit . . . . . Probit model with continuous endogenous regressors 793
ivprobit postestimation . . . . . Postestimation tools for ivprobit 806
ivregress . . . . . Single-equation instrumental-variables regression 810
ivregress postestimation . . . . . Postestimation tools for ivregress 826
ivtobit . . . . . Tobit model with continuous endogenous regressors 843
ivtobit postestimation . . . . . Postestimation tools for ivtobit 853

jackknife . . . . . Jackknife estimation 857
jackknife postestimation . . . . . Postestimation tools for jackknife 869

kappa . . . . . Interrater agreement 870
kdensity . . . . . Univariate kernel density estimation 884
ksmirnov . . . . . Kolmogorov–Smirnov equality-of-distributions test 894
kwallis . . . . . Kruskal–Wallis equality-of-populations rank test 899

ladder . . . . . Ladder of powers 902
level . . . . . Set default confidence level 909
lincom . . . . . Linear combinations of estimators 911
linktest . . . . . Specification link test for single-equation models 918
lnskew0 . . . . . Find zero-skewness log or Box–Cox transform 924
log . . . . . Echo copy of session to file 928
logistic . . . . . Logistic regression, reporting odds ratios 932
logistic postestimation . . . . . Postestimation tools for logistic 943
logit . . . . . Logistic regression, reporting coefficients 970
logit postestimation . . . . . Postestimation tools for logit 983
loneway . . . . . Large one-way ANOVA, random effects, and reliability 989
lowess . . . . . Lowess smoothing 995
lpoly . . . . . Kernel-weighted local polynomial smoothing 1001
lrtest . . . . . Likelihood-ratio test after estimation 1011
lv . . . . . Letter-value displays 1021

margins . . . . . Marginal means, predictive margins, and marginal effects 1027
margins postestimation . . . . . Postestimation tools for margins 1080
margins, contrast . . . . . Contrasts of margins 1082
margins, pwcompare . . . . . Pairwise comparisons of margins 1094
marginsplot . . . . . Graph results from margins (profile plots, etc.) 1099
matsize . . . . . Set the maximum number of variables in a model 1130
maximize . . . . . Details of iterative maximization 1132
mean . . . . . Estimate means 1139
mean postestimation . . . . . Postestimation tools for mean 1150

meta . . . . . Meta-analysis 1152
mfp . . . . . Multivariable fractional polynomial models 1153
mfp postestimation . . . . . Postestimation tools for mfp 1164
misstable . . . . . Tabulate missing values 1165
mkspline . . . . . Linear and restricted cubic spline construction 1174
ml . . . . . Maximum likelihood estimation 1180
mlogit . . . . . Multinomial (polytomous) logistic regression 1207
mlogit postestimation . . . . . Postestimation tools for mlogit 1221
more . . . . . The —more— message 1232
mprobit . . . . . Multinomial probit regression 1234
mprobit postestimation . . . . . Postestimation tools for mprobit 1241
mvreg . . . . . Multivariate regression 1244
mvreg postestimation . . . . . Postestimation tools for mvreg 1251

nbreg . . . . . Negative binomial regression 1253
nbreg postestimation . . . . . Postestimation tools for nbreg and gnbreg 1265
nestreg . . . . . Nested model statistics 1269
net . . . . . Install and manage user-written additions from the Internet 1275
net search . . . . . Search the Internet for installable packages 1293
netio . . . . . Control Internet connections 1297
news . . . . . Report Stata news 1300
nl . . . . . Nonlinear least-squares estimation 1301
nl postestimation . . . . . Postestimation tools for nl 1321
nlcom . . . . . Nonlinear combinations of estimators 1323
nlogit . . . . . Nested logit regression 1334
nlogit postestimation . . . . . Postestimation tools for nlogit 1356
nlsur . . . . . Estimation of nonlinear systems of equations 1361
nlsur postestimation . . . . . Postestimation tools for nlsur 1383
nptrend . . . . . Test for trend across ordered groups 1385

ologit . . . . . Ordered logistic regression 1389
ologit postestimation . . . . . Postestimation tools for ologit 1398
oneway . . . . . One-way analysis of variance 1402
oprobit . . . . . Ordered probit regression 1412
oprobit postestimation . . . . . Postestimation tools for oprobit 1418
orthog . . . . . Orthogonalize variables and compute orthogonal polynomials 1422

pcorr . . . . . Partial and semipartial correlation coefficients 1429
permute . . . . . Monte Carlo permutation tests 1432
pk . . . . . Pharmacokinetic (biopharmaceutical) data 1442
pkcollapse . . . . . Generate pharmacokinetic measurement dataset 1450
pkcross . . . . . Analyze crossover experiments 1453
pkequiv . . . . . Perform bioequivalence tests 1462
pkexamine . . . . . Calculate pharmacokinetic measures 1469
pkshape . . . . . Reshape (pharmacokinetic) Latin-square data 1475
pksumm . . . . . Summarize pharmacokinetic data 1483
poisson . . . . . Poisson regression 1488
poisson postestimation . . . . . Postestimation tools for poisson 1497
predict . . . . . Obtain predictions, residuals, etc., after estimation 1503
predictnl . . . . . Obtain nonlinear predictions, standard errors, etc., after estimation 1514
probit . . . . . Probit regression 1526
probit postestimation . . . . . Postestimation tools for probit 1538

proportion ..... Estimate proportions 1542
proportion postestimation ..... Postestimation tools for proportion 1547
prtest ..... One- and two-sample tests of proportions 1548
pwcompare ..... Pairwise comparisons 1553
pwcompare postestimation ..... Postestimation tools for pwcompare 1581
pwmean ..... Pairwise comparisons of means 1583
pwmean postestimation ..... Postestimation tools for pwmean 1593

qc ..... Quality control charts 1595
qreg ..... Quantile regression 1610
qreg postestimation ..... Postestimation tools for qreg, iqreg, sqreg, and bsqreg 1630
query ..... Display system parameters 1632

ranksum ..... Equality tests on unmatched data 1639
ratio ..... Estimate ratios 1645
ratio postestimation ..... Postestimation tools for ratio 1654
reg3 ..... Three-stage estimation for systems of simultaneous equations 1655
reg3 postestimation ..... Postestimation tools for reg3 1676
regress ..... Linear regression 1679
regress postestimation ..... Postestimation tools for regress 1704
regress postestimation time series ..... Postestimation tools for regress with time series 1749
#review ..... Review previous commands 1759
roc ..... Receiver operating characteristic (ROC) analysis 1760
roccomp ..... Tests of equality of ROC areas 1762
rocfit ..... Parametric ROC models 1774
rocfit postestimation ..... Postestimation tools for rocfit 1781
rocreg ..... Receiver operating characteristic (ROC) regression 1785
rocreg postestimation ..... Postestimation tools for rocreg 1837
rocregplot ..... Plot marginal and covariate-specific ROC curves after rocreg 1852
roctab ..... Nonparametric ROC analysis 1871
rologit ..... Rank-ordered logistic regression 1881
rologit postestimation ..... Postestimation tools for rologit 1898
rreg ..... Robust regression 1900
rreg postestimation ..... Postestimation tools for rreg 1907
runtest ..... Test for random order 1909

sampsi ..... Sample size and power for means and proportions 1915
saved results ..... Saved results 1926
scobit ..... Skewed logistic regression 1931
scobit postestimation ..... Postestimation tools for scobit 1940
sdtest ..... Variance-comparison tests 1943
search ..... Search Stata documentation 1950
serrbar ..... Graph standard error bar chart 1956
set ..... Overview of system parameters 1959
set cformat ..... Format settings for coefficient tables 1971
set_defaults ..... Reset system parameters to original Stata defaults 1974
set emptycells ..... Set what to do with empty cells in interactions 1976
set seed ..... Specify initial value of random-number seed 1977
set showbaselevels ..... Display settings for coefficient tables 1982
signrank ..... Equality tests on matched data 1986
simulate ..... Monte Carlo simulations 1992
sj ..... Stata Journal and STB installation instructions 1999

sktest . . . Skewness and kurtosis test for normality 2002
slogit . . . Stereotype logistic regression 2007
slogit postestimation . . . Postestimation tools for slogit 2021
smooth . . . Robust nonlinear smoother 2025
spearman . . . Spearman's and Kendall's correlations 2033
spikeplot . . . Spike plots and rootograms 2042
ssc . . . Install and uninstall packages from SSC 2046
stem . . . Stem-and-leaf displays 2053
stepwise . . . Stepwise estimation 2057
suest . . . Seemingly unrelated estimation 2067
summarize . . . Summary statistics 2085
sunflower . . . Density-distribution sunflower plots 2094
sureg . . . Zellner's seemingly unrelated regression 2100
sureg postestimation . . . Postestimation tools for sureg 2108
swilk . . . Shapiro–Wilk and Shapiro–Francia tests for normality 2111
symmetry . . . Symmetry and marginal homogeneity tests 2115

table . . . Tables of summary statistics 2123
tabstat . . . Display table of summary statistics 2133
tabulate oneway . . . One-way tables of frequencies 2138
tabulate twoway . . . Two-way tables of frequencies 2146
tabulate, summarize() . . . One- and two-way tables of summary statistics 2162
test . . . Test linear hypotheses after estimation 2167
testnl . . . Test nonlinear hypotheses after estimation 2186
tetrachoric . . . Tetrachoric correlations for binary variables 2195
tnbreg . . . Truncated negative binomial regression 2205
tnbreg postestimation . . . Postestimation tools for tnbreg 2213
tobit . . . Tobit regression 2217
tobit postestimation . . . Postestimation tools for tobit 2224
total . . . Estimate totals 2229
total postestimation . . . Postestimation tools for total 2235
tpoisson . . . Truncated Poisson regression 2237
tpoisson postestimation . . . Postestimation tools for tpoisson 2244
translate . . . Print and translate logs 2247
treatreg . . . Treatment-effects model 2257
treatreg postestimation . . . Postestimation tools for treatreg 2269
truncreg . . . Truncated regression 2272
truncreg postestimation . . . Postestimation tools for truncreg 2279
ttest . . . Mean-comparison tests 2282

update . . . Update Stata 2291

vce_option . . . Variance estimators 2294
view . . . View files and logs 2299
vwls . . . Variance-weighted least squares 2303
vwls postestimation . . . Postestimation tools for vwls 2309

which . . . Display location and version for an ado-file 2311

xi . . . Interaction expansion 2313

zinb . . . Zero-inflated negative binomial regression 2324
zinb postestimation . . . Postestimation tools for zinb 2331
zip . . . Zero-inflated Poisson regression 2334

zip postestimation . . . . . Postestimation tools for zip 2340

Author index 2343
Subject index 2357

Cross-referencing the documentation

When reading this manual, you will find references to other Stata manuals. For example,

[U] **26 Overview of Stata estimation commands**
[XT] **xtabond**
[D] **reshape**

The first example is a reference to chapter 26, *Overview of Stata estimation commands*, in the *User's Guide*; the second is a reference to the `xtabond` entry in the *Longitudinal-Data/Panel-Data Reference Manual*; and the third is a reference to the `reshape` entry in the *Data-Management Reference Manual*.

All the manuals in the Stata Documentation have a shorthand notation:

[GSM]	*Getting Started with Stata for Mac*
[GSU]	*Getting Started with Stata for Unix*
[GSW]	*Getting Started with Stata for Windows*
[U]	*Stata User's Guide*
[R]	*Stata Base Reference Manual*
[D]	*Stata Data-Management Reference Manual*
[G]	*Stata Graphics Reference Manual*
[XT]	*Stata Longitudinal-Data/Panel-Data Reference Manual*
[MI]	*Stata Multiple-Imputation Reference Manual*
[MV]	*Stata Multivariate Statistics Reference Manual*
[P]	*Stata Programming Reference Manual*
[SEM]	*Stata Structural Equation Modeling Reference Manual*
[SVY]	*Stata Survey Data Reference Manual*
[ST]	*Stata Survival Analysis and Epidemiological Tables Reference Manual*
[TS]	*Stata Time-Series Reference Manual*
[I]	*Stata Quick Reference and Index*
[M]	*Mata Reference Manual*

Detailed information about each of these manuals may be found online at

http://www.stata-press.com/manuals/

Title

intro — Introduction to base reference manual

Description

This entry describes the organization of the reference manuals.

Remarks

The complete list of reference manuals is as follows:

[R]	*Stata Base Reference Manual*
	Volume 1, A–F
	Volume 2, G–M
	Volume 3, N–R
	Volume 4, S–Z
[D]	*Stata Data-Management Reference Manual*
[G]	*Stata Graphics Reference Manual*
[XT]	*Stata Longitudinal-Data/Panel-Data Reference Manual*
[MI]	*Stata Multiple-Imputation Reference Manual*
[MV]	*Stata Multivariate Statistics Reference Manual*
[P]	*Stata Programming Reference Manual*
[SEM]	*Stata Structural Equation Modeling Reference Manual*
[SVY]	*Stata Survey Data Reference Manual*
[ST]	*Stata Survival Analysis and Epidemiological Tables Reference Manual*
[TS]	*Stata Time-Series Reference Manual*
[I]	*Stata Quick Reference and Index*
[M]	*Mata Reference Manual*

When we refer to "reference manuals", we mean all manuals listed above.

When we refer to the *Base Reference Manual*, we mean just the four-volume *Base Reference Manual*, known as [R].

When we refer to the specialty manuals, we mean all the manuals listed above except [R] and [I], the *Stata Quick Reference and Index*.

Detailed information about each of these manuals can be found online at

http://www.stata-press.com/manuals/

Arrangement of the reference manuals

Each manual contains the following sections:

- Table of contents.
  At the beginning of volume 1 of [R], the *Base Reference Manual*, is a table of contents for the four volumes.
- Cross-referencing the documentation.
  This section lists all the manuals and explains how they are cross-referenced.
- Introduction.
  This entry—usually called intro—provides an overview of the manual. In the specialty manuals, this introduction suggests entries that you might want to read first and provides information about new features.

  Each specialty manual contains an overview of the commands described in it.
- Entries.
  Entries are arranged in alphabetical order. Most entries describe Stata commands, but some entries discuss concepts, and others provide overviews.

  Entries that describe estimation commands are followed by an entry discussing postestimation commands that are available for use after the estimation command. For example, the **xtlogit** entry in the [XT] manual is followed by the **xtlogit postestimation** entry.
- Index.
  At the end of each manual is an index. The index for the entire four-volume *Base Reference Manual* is found at the end of the fourth volume.

The *Quick Reference and Index*, [I], contains a combined index for all the manuals and a subject table of contents for all the manuals and the *User's Guide*. It also contains quick-reference information on many subjects, such as the estimation commands.

To find information and commands quickly, use Stata's `search` command; see [R] **search** (see the entry `search` in the [R] manual). You can broaden your search to the Internet by using `search, all` to find commands and extensions written by Stata users.

Arrangement of each entry

Entries in the Stata reference manuals, except the [M] and [SEM] manuals, generally contain the following sections, which are explained below:

Syntax
Menu
Description
Options
Remarks
Saved results
Methods and formulas
References
Also see

Syntax

A command's syntax diagram shows how to type the command, indicates all possible options, and gives the minimal allowed abbreviations for all the items in the command. For instance, the syntax diagram for the `summarize` command is

`summarize` [*varlist*] [*if*] [*in*] [*weight*] [, *options*]

options	Description
Main	
`detail`	display additional statistics
`meanonly`	suppress the display; calculate only the mean; programmer's option
`format`	use variable's display format
`separator(#)`	draw separator line after every # variables; default is `separator(5)`
display_options	control spacing and base and empty cells

varlist may contain factor variables; see [U] **11.4.3 Factor variables**.
varlist may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`by` is allowed; see [D] **by**.
`aweights`, `fweights`, and `iweights` are allowed. However, `iweights` may not be used with the `detail` option; see [U] **11.1.6 weight**.

Items in the `typewriter-style font` should be typed exactly as they appear in the diagram, although they may be abbreviated. `Underlining` indicates the shortest abbreviations where abbreviations are allowed. For instance, `summarize` may be abbreviated `su`, `sum`, `summ`, etc., or it may be spelled out completely. Items in the typewriter font that are not underlined may not be abbreviated.

Square brackets denote optional items. In the syntax diagram above, *varlist*, *if*, *in*, *weight*, and the *options* are optional.

The *options* are listed in a table immediately following the diagram, along with a brief description of each.

Items typed in *italics* represent arguments for which you are to substitute variable names, observation numbers, and the like.

The diagrams use the following symbols:

#	Indicates a literal number, for example, `5`; see [U] **12.2 Numbers**.
[ ]	Anything enclosed in brackets is optional.
{ }	At least one of the items enclosed in braces must appear.
|	The vertical bar separates alternatives.
%fmt	Any Stata format, for example, `%8.2f`; see [U] **12.5 Formats: Controlling how data are displayed**.
depvar	The dependent variable in an estimation command; see [U] **20 Estimation and postestimation commands**.
exp	Any algebraic expression, for example, `(5+myvar)/2`; see [U] **13 Functions and expressions**.
filename	Any filename; see [U] **11.6 Filenaming conventions**.

indepvars The independent variables in an estimation command; see [U] **20 Estimation and postestimation commands**.

newvar A variable that will be created by the current command; see [U] **11.4.2 Lists of new variables**.

numlist A list of numbers; see [U] **11.1.8 numlist**.

oldvar A previously created variable; see [U] **11.4.1 Lists of existing variables**.

options A list of options; see [U] **11.1.7 options**.

range An observation range, for example, `5/20`; see [U] **11.1.4 in range**.

"*string*" Any string of characters enclosed in double quotes; see [U] **12.4 Strings**.

varlist A list of variable names; see [U] **11.4 varlists**. If *varlist* allows factor variables, a note to that effect will be shown below the syntax diagram; see [U] **11.4.3 Factor variables**. If *varlist* allows time-series operators, a note to that effect will be shown below the syntax diagram; see [U] **11.4.4 Time-series varlists**.

varname A variable name; see [U] **11.3 Naming conventions**.

weight A [*wgttype*=*exp*] modifier; see [U] **11.1.6 weight** and [U] **20.22 Weighted estimation**.

xvar The variable to be displayed on the horizontal axis.

yvar The variable to be displayed on the vertical axis.

The *Syntax* section will indicate whether factor variables or time-series operators may be used with a command. `summarize` allows factor variables and time-series operators.

If a command allows prefix commands, this will be indicated immediately following the table of options. `summarize` allows `by`.

If a command allows weights, the types of weights allowed will be specified, with the default weight listed first. `summarize` allows `aweights`, `fweights`, and `iweights`, and if the type of weight is not specified, the default is `aweights`.

Menu

A menu indicates how the dialog box for the command may be accessed using the menu system.

Description

Following the syntax diagram is a brief description of the purpose of the command.

Options

If the command allows any options, they are explained here, and for dialog users the location of the options in the dialog is indicated. For instance, in the **logistic** entry in this manual, the *Options* section looks like this:

Model

. . .

SE/Robust

. . .

Reporting

...

Maximization

...

Remarks

The explanations under *Description* and *Options* are exceedingly brief and technical; they are designed to provide a quick summary. The remarks explain in English what the preceding technical jargon means. Examples are used to illustrate the command.

Saved results

Commands are classified as e-class, r-class, s-class, or n-class, according to whether they save calculated results in `e()`, `r()`, `s()`, or not at all. These results can then be used in subroutines by other programs (ado-files). Such saved results are documented here; see [U] **18.8 Accessing results calculated by other programs** and [U] **18.9 Accessing results calculated by estimation commands**.

Methods and formulas

The techniques and formulas used in obtaining the results are described here as tersely and technically as possible. If a command is implemented as an ado-file, that is indicated here.

Title

adoupdate — Update user-written ado-files

Syntax

`adoupdate` [*pkglist*] [`,` *options*]

options	Description
`update`	perform update; default is to list packages that have updates, but not to update them
`all`	include packages that might have updates; default is to list or update only packages that are known to have updates
`ssconly`	check only packages obtained from SSC; default is to check all installed packages
`dir(`*dir*`)`	check packages installed in *dir*; default is to check those installed in PLUS
`verbose`	provide output to assist in debugging network problems

Description

User-written additions to Stata are called packages. These packages can add remarkable abilities to Stata. Packages are found and installed by using `ssc`, `findit`, and `net`; see [R] **ssc**, [R] **search**, and [R] **net**.

User-written packages are updated by their developers, just as official Stata software is updated by StataCorp.

To determine whether your official Stata software is up to date, and to update it if it is not, you use `update`; see [R] **update**.

To determine whether your user-written additions are up to date, and to update them if they are not, you use `adoupdate`.

Options

`update` specifies that packages with updates be updated. The default is simply to list the packages that could be updated without actually performing the update.

The first time you `adoupdate`, do not specify this option. Once you see `adoupdate` work, you will be more comfortable with it. Then type

```
. adoupdate, update
```

The packages that can be updated will be listed and updated.

`all` is rarely specified. Sometimes, `adoupdate` cannot determine whether a package you previously installed has been updated. `adoupdate` can determine that the package is still available over the web but is unsure whether the package has changed. Usually, the package has not changed, but if you want to be certain that you are using the latest version, reinstall from the source.

Specifying `all` does this. Typing

```
. adoupdate, all
```

adds such packages to the displayed list as needing updating but does not update them. Typing

```
. adoupdate, update all
```

lists such packages and updates them.

`ssconly` is a popular option. Many packages are available from the Statistical Software Components (SSC) archive—often called the Boston College Archive—which is provided at http://repec.org. Many users find most of what they want there. See [R] **ssc** for more information on the SSC.

`ssconly` specifies that `adoupdate` check only packages obtained from that source. Specifying this option is popular because SSC always provides distribution dates, and so `adoupdate` can be certain whether an update exists.

`dir(`*dir*`)` specifies which installed packages be checked. The default is `dir(PLUS)`, and that is probably correct. If you are responsible for maintaining a large system, however, you may have previously installed packages in `dir(SITE)`, where they are shared across users. See [P] **sysdir** for an explanation of these directory codewords. You may also specify an actual directory name, such as `C:\mydir`.

`verbose` is specified when you suspect network problems. It provides more detailed output that may help you diagnose the problem.

Remarks

Do not confuse `adoupdate` with `update`. Use `adoupdate` to update user-written files. Use `update` to update the components (including ado-files) of the official Stata software. To use either command, you must be connected to the Internet.

Remarks are presented under the following headings:

Using adoupdate
Possible problem the first time you run adoupdate and the solution
Notes for developers

Using adoupdate

The first time you try `adoupdate`, type

```
. adoupdate
```

That is, do not specify the `update` option. `adoupdate` without `update` produces a report but does not update any files. The first time you run `adoupdate`, you may see messages such as

```
. adoupdate
  (note:  package utx was installed more than once; older copy removed)
  (remaining output omitted)
```

Having the same packages installed multiple times is common; `adoupdate` cleans that up.

The second time you run `adoupdate`, pick one package to update. Suppose that the report indicates that package `st0008` has an update available. Type

```
. adoupdate st0008, update
```

You can specify one or many packages after the `adoupdate` command. You can even use wildcards such as `st*` to mean all packages that start with `st` or `st*8` to mean all packages that start with `st` and end with `8`. You can do that with or without the `update` option.

Finally, you can let adoupdate update all your user-written additions:

```
. adoupdate, update
```

Possible problem the first time you run adoupdate and the solution

The first time you run adoupdate, you might get many duplicate messages:

```
. adoupdate
  (note: package ___ installed more than once; older copy removed)
  (note: package ___ installed more than once; older copy removed)
  (note: package ___ installed more than once; older copy removed)
  ...
  (note: package ___ installed more than once; older copy removed)
  (remaining output omitted)
```

Some users have hundreds of duplicates. You might even see the same package name repeated more than once:

```
(note: package stylus installed more than once; older copy removed)
(note: package stylus installed more than once; older copy removed)
```

That means that the package was duplicated twice.

Stata tolerates duplicates, and you did nothing wrong when you previously installed and updated packages. adoupdate, however, needs the duplicates removed, mainly so that it does not keep checking the same files.

The solution is to just let adoupdate run. adoupdate will run faster next time, when there are no (or just a few) duplicates.

Notes for developers

adoupdate reports whether an installed package is up to date by comparing its distribution date with that of the package available over the web.

If you are distributing software, include the line

```
d Distribution-Date: date
```

somewhere in your .pkg file. The capitalization of Distribution-Date does not matter, but include the hyphen and the colon as shown. Code the date in either of two formats:

all numeric:	*yyyymmdd*, for example, 20110701
Stata standard:	*ddMONyyyy*, for example, 01jul2011

Saved results

adoupdate saves the following in r():

Macros

r(pkglist) a space-separated list of package names that need updating (update not specified) or that were updated (update specified)

Methods and formulas

`adoupdate` is implemented as an ado-file.

Title

alpha — Compute interitem correlations (covariances) and Cronbach's alpha

Syntax

`alpha` *varlist* [*if*] [*in*] [, *options*]

options	Description
Options	
`asis`	take sign of each item as is
`casewise`	delete cases with missing values
`detail`	list individual interitem correlations and covariances
`generate(`*newvar*`)`	save the generated scale in *newvar*
`item`	display item-test and item-rest correlations
`label`	include variable labels in output table
`min(#)`	must have at least # observations for inclusion
`reverse(`*varlist*`)`	reverse signs of these variables
`std`	standardize items in the scale to mean 0, variance 1

`by` is allowed; see [D] **by**.

Menu

Statistics > Multivariate analysis > Cronbach's alpha

Description

`alpha` computes the interitem correlations or covariances for all pairs of variables in *varlist* and Cronbach's α statistic for the scale formed from them. At least two variables must be specified with `alpha`.

Options

Options

`asis` specifies that the sense (sign) of each item be taken as presented in the data. The default is to determine the sense empirically and reverse the scorings for any that enter negatively.

`casewise` specifies that cases with missing values be deleted listwise. The default is pairwise computation of covariances and correlations.

`detail` lists the individual interitem correlations and covariances.

`generate(`*newvar*`)` specifies that the scale constructed from *varlist* be stored in *newvar*. Unless `asis` is specified, the sense of items entering negatively is automatically reversed. If `std` is also specified, the scale is constructed by using standardized (mean 0, variance 1) values of the individual items. Unlike most Stata commands, `generate()` does not use casewise deletion. A score is created for every observation for which there is a response to at least one item (one variable in *varlist* is not missing). The summative score is divided by the number of items over which the sum is calculated.

`item` specifies that item-test and item-rest correlations and the effects of removing an item from the scale be displayed. `item` is valid only when more than two variables are specified in *varlist*.

`label` requests that the detailed output table be displayed in a compact format that enables the inclusion of variable labels.

`min(#)` specifies that only cases with at least # observations be included in the computations. `casewise` is a shorthand for `min(`*k*`)`, where *k* is the number of variables in *varlist*.

`reverse(`*varlist*`)` specifies that the signs (directions) of the variables (items) in *varlist* be reversed. Any variables specified in `reverse()` that are not also included in `alpha`'s *varlist* are ignored.

`std` specifies that the items in the scale be standardized (mean 0, variance 1) before summing.

Remarks

Cronbach's alpha (Cronbach 1951) assesses the reliability of a summative rating (Likert 1932) scale composed of the variables (called *items*) specified. The set of items is often called a *test* or *battery*. A scale is simply the sum of the individual item scores, reversing the scoring for statements that have negative correlations with the factor (for example, attitude) being measured. Scales can be formed by using the raw item scores or standardized item scores.

The reliability α is defined as the square of the correlation between the measured scale and the underlying factor. If you think of a test as being composed of a random sample of items from a hypothetical domain of items designed to measure the same thing, α represents the expected correlation of one test with an alternative form containing the same number of items. The square root of α is the estimated correlation of a test with errorless true scores (Nunnally and Bernstein 1994, 235).

In addition to reporting α, `alpha` generates the summative scale from the items (variables) specified and automatically reverses the sense of any when necessary. Stata's decision can be overridden by specifying the `reverse(`*varlist*`)` option.

Because it concerns reliability in measuring an unobserved factor, α is related to factor analysis. The test should be designed to measure one factor, and, because the scale will be composed of an unweighted sum, the factor loadings should all contribute roughly equal information to the score. Both of these assumptions can be verified with `factor`; see [MV] **factor**. Equality of factor loadings can also be assessed by using the `item` option.

▷ Example 1

To illustrate `alpha`, we apply it, first without and then with the `item` option, to the automobile dataset after randomly introducing missing values:

```
. use http://www.stata-press.com/data/r12/automiss
(1978 Automobile Data)
. alpha price headroom rep78 trunk weight length turn displ, std
Test scale = mean(standardized items)
Reversed item: rep78
Average interitem correlation:      0.5251
Number of items in the scale:            8
Scale reliability coefficient:      0.8984
```

The scale derived from our somewhat arbitrarily chosen automobile items (variables) appears to be reasonable because the estimated correlation between it and the underlying factor it measures is $\sqrt{0.8984} \approx 0.9478$ and the estimated correlation between this battery of eight items and all other eight-item batteries from the same domain is 0.8984. Because the "items" are not on the same scale,

it is important that `std` was specified so that the scale and its reliability were based on the sum of standardized variables. We could obtain the scale in a new variable called `sc` with the `gen(sc)` option.

Though the scale appears reasonable, we include the `item` option to determine if all the items fit the scale:

```
. alpha price headroom rep78 trunk weight length turn displ, std item
Test scale = mean(standardized items)
```

Item	Obs	Sign	item-test correlation	item-rest correlation	average interitem correlation	alpha
price	70	+	0.5260	0.3719	0.5993	0.9128
headroom	66	+	0.6716	0.5497	0.5542	0.8969
rep78	61	-	0.4874	0.3398	0.6040	0.9143
trunk	69	+	0.7979	0.7144	0.5159	0.8818
weight	64	+	0.9404	0.9096	0.4747	0.8635
length	69	+	0.9382	0.9076	0.4725	0.8625
turn	66	+	0.8678	0.8071	0.4948	0.8727
displacement	63	+	0.8992	0.8496	0.4852	0.8684
Test scale					0.5251	0.8984

"Test" denotes the additive scale; here 0.5251 is the average interitem correlation, and 0.8984 is the alpha coefficient for a test scale based on all items.

"Obs" shows the number of nonmissing values of the items; "Sign" indicates the direction in which an item variable entered the scale; "`-`" denotes that the item was reversed. The remaining four columns in the table provide information on the effect of one item on the scale.

Column four gives the item-test correlations. Apart from the sign of the correlation for items that entered the scale in reversed order, these correlations are the same numbers as those computed by the commands

```
. alpha price headroom rep78 trunk weight length turn displ, std gen(sc)
. pwcorr sc price headroom rep78 trunk weight length turn displ
```

Typically, the item-test correlations should be roughly the same for all items. Item-test correlations may not be adequate to detect items that fit poorly because the poorly fitting items may distort the scale. Accordingly, it may be more useful to consider item-rest correlations (Nunnally and Bernstein 1994), that is, the correlation between an item and the scale that is formed by all other items. The average interitem correlations (covariances if `std` is omitted) of all items, excluding one, are shown in column six. Finally, column seven gives Cronbach's α for the test scale, which consists of all but the one item.

Here neither the `price` item nor the `rep78` item seems to fit well in the scale in all respects. The item-test and item-rest correlations of `price` and `rep78` are much lower than those of the other items. The average interitem correlation increases substantially by removing either `price` or `rep78`; apparently, they do not correlate strongly with the other items. Finally, we see that Cronbach's α coefficient will increase from 0.8984 to 0.9128 if the `price` item is dropped, and it will increase from 0.8984 to 0.9143 if `rep78` is dropped. For well-fitting items, we would of course expect that α decreases by shortening the test.

◁

▷ Example 2

The variable names for the automobile data are reasonably informative. This may not always be true; items in batteries commonly used to measure personality traits, attitudes, values, etc., are usually named with indexed names such as `item12a`, `item12b`, etc. The `label` option forces `alpha` to produce the same statistical information in a more compact format that leaves room to include variable (item) labels. In this compact format, `alpha` excludes the number of nonmissing values of the items, displays the statistics using fewer digits, and uses somewhat cryptic headers:

```
. alpha price headroom rep78 trunk weight length turn displ, std item label detail
Test scale = mean(standardized items)
```

Items	S	it-cor	ir-cor	ii-cor	alpha	label
price	+	0.526	0.372	0.599	0.913	Price
headroom	+	0.672	0.550	0.554	0.897	Headroom (in.)
rep78	-	0.487	0.340	0.604	0.914	Repair Record 1978
trunk	+	0.798	0.714	0.516	0.882	Trunk space (cu. ft.)
weight	+	0.940	0.910	0.475	0.863	Weight (lbs.)
length	+	0.938	0.908	0.473	0.862	Length (in.)
turn	+	0.868	0.807	0.495	0.873	Turn Circle (ft.)
displacement	+	0.899	0.850	0.485	0.868	Displacement (cu. in.)
Test scale				0.525	0.898	mean(standardized items)

```
Interitem correlations (reverse applied) (obs=pairwise, see below)
```

	price	headroom	rep78	trunk
price	1.0000			
headroom	0.1174	1.0000		
rep78	-0.0479	0.1955	1.0000	
trunk	0.2748	0.6841	0.2777	1.0000
weight	0.5093	0.5464	0.3624	0.6486
length	0.4511	0.5823	0.3162	0.7404
turn	0.3528	0.4067	0.4715	0.5900
displacement	0.5537	0.5166	0.3391	0.6471

	weight	length	turn	displacement
weight	1.0000			
length	0.9425	1.0000		
turn	0.8712	0.8589	1.0000	
displacement	0.8753	0.8422	0.7723	1.0000

```
Pairwise number of observations
```

	price	headroom	rep78	trunk
price	70			
headroom	62	66		
rep78	59	54	61	
trunk	65	61	59	69
weight	60	56	52	60
length	66	61	58	64
turn	62	58	56	62
displacement	59	58	51	58

	weight	length	turn	displacement
weight	64			
length	60	69		
turn	57	61	66	
displacement	54	58	56	63

Because the `detail` option was also specified, the interitem correlation matrix was printed, together with the number of observations used for each entry (because these varied across the matrix). Note the negative sign attached to `rep78` in the output, indicating the sense in which it entered the scale.

Better-looking output with less-cryptic headers is produced if the linesize is set to a value of at least 100:

```
. set linesize 100
. alpha price headroom rep78 trunk weight length turn displ, std item label
Test scale = mean(standardized items)
```

Item	Obs	Sign	item-test corr.	item-rest corr.	interitem corr.	alpha	Label
price	70	+	0.5260	0.3719	0.5993	0.9128	Price
headroom	62	+	0.6716	0.5497	0.5542	0.8969	Headroom (in.)
rep78	59	-	0.4874	0.3398	0.6040	0.9143	Repair Record 1978
trunk	65	+	0.7979	0.7144	0.5159	0.8818	Trunk space (cu. ft.)
weight	60	+	0.9404	0.9096	0.4747	0.8635	Weight (lbs.)
length	66	+	0.9382	0.9076	0.4725	0.8625	Length (in.)
turn	62	+	0.8678	0.8071	0.4948	0.8727	Turn Circle (ft.)
displacement	59	+	0.8992	0.8496	0.4852	0.8684	Displacement (cu. in.)
Test scale					0.5251	0.8984	mean(standardized items)

◁

Users of `alpha` require some standard for judging values of α. We paraphrase Nunnally and Bernstein (1994, 265): In the early stages of research, modest reliability of 0.70 or higher will suffice; values in excess of 0.80 often waste time and funds. In contrast, where measurements on individuals are of interest, a reliability of 0.80 may not be nearly high enough. Even with a reliability of 0.90, the standard error of measurement is almost one-third as large as the standard deviation of test scores; a reliability of 0.90 is the minimum that should be tolerated, and a reliability of 0.95 should be considered the desirable standard.

Saved results

`alpha` saves the following in `r()`:

Scalars

`r(alpha)`	scale reliability coefficient
`r(k)`	number of items in the scale
`r(cov)`	average interitem covariance
`r(rho)`	average interitem correlation if `std` is specified

Matrices

`r(Alpha)`	scale reliability coefficient
`r(ItemTestCorr)`	item-test correlation
`r(ItemRestCorr)`	item-rest correlation
`r(MeanInterItemCov)`	average interitem covariance
`r(MeanInterItemCorr)`	average interitem correlation if `std` is specified

If the `item` option is specified, results are saved as row matrices for the `k` subscales when one variable is removed.

Methods and formulas

`alpha` is implemented as an ado-file.

Let x_i, $i = 1, \ldots, k$, be the variables over which α is to be calculated. Let s_i be the sign with which x_i enters the scale. If `asis` is specified, $s_i = 1$ for all i. Otherwise, principal-factor analysis is performed on x_i, and the first factor's score is predicted; see [MV] **factor**. s_i is -1 if correlation of the x_i and the predicted score is negative and $+1$ otherwise.

Let r_{ij} be the correlation between x_i and x_j, c_{ij} be the covariance, and n_{ij} be the number of observations used in calculating the correlation or covariance. The average correlation is

$$\overline{r} = \frac{\sum_{i=2}^{k}\sum_{j=1}^{i-1} s_i s_j n_{ij} r_{ij}}{\sum_{i=2}^{k}\sum_{j=1}^{i-1} n_{ij}}$$

and the average covariance similarly is

$$\overline{c} = \frac{\sum_{i=2}^{k}\sum_{j=1}^{i-1} s_i s_j n_{ij} c_{ij}}{\sum_{i=2}^{k}\sum_{j=1}^{i-1} n_{ij}}$$

Let c_{ii} denote the variance of x_i, and define the average variance as

$$\overline{v} = \frac{\sum_{i=1}^{k} n_{ii} c_{ii}}{\sum_{i=1}^{k} n_{ii}}$$

If `std` is specified, the scale reliability α is calculated as defined by the general form of the Spearman–Brown Prophecy Formula (Nunnally and Bernstein 1994, 232; Allen and Yen 1979, 85–88):

$$\alpha = \frac{k\overline{r}}{1 + (k-1)\overline{r}}$$

This expression corresponds to α under the assumption that the summative rating is the sum of the standardized variables (Nunnally and Bernstein 1994, 234). If `std` is not specified, α is defined (Nunnally and Bernstein 1994, 232 and 234) as

$$\alpha = \frac{k\overline{c}}{\overline{v} + (k-1)\overline{c}}$$

Let x_{ij} reflect the value of item i in the jth observation. If `std` is specified, the jth value of the scale computed from the k x_{ij} items is

$$S_j = \frac{1}{k_j}\sum_{i=1}^{k} s_i S(x_{ij})$$

where $S()$ is the function that returns the standardized (mean 0, variance 1) value if x_{ij} is not missing and returns zero if x_{ij} is missing. k_j is the number of nonmissing values in x_{ij}, $i = 1, \ldots, k$. If `std` is not specified, $S()$ is the function that returns x_{ij} or returns missing if x_{ij} is missing.

Lee Joseph Cronbach (1916–2001) was an American psychometrician and educational psychologist who worked principally on measurement theory, program evaluation, and instruction. He taught and researched at the State College of Washington, the University of Chicago, the University of Illinois, and Stanford University. Cronbach's initial paper on alpha led to a theory of test reliability.

Acknowledgment

This improved version of `alpha` was written by Jeroen Weesie, Department of Sociology, Utrecht University, The Netherlands.

Title

ameans — Arithmetic, geometric, and harmonic means

Syntax

`ameans` [*varlist*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Main	
`add(#)`	add # to each variable in *varlist*
`only`	add # only to variables with nonpositive values
`level(#)`	set confidence level; default is `level(95)`

`by` is allowed; see [D] **by**.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Arith./geometric/harmonic means

Description

`ameans` computes the arithmetic, geometric, and harmonic means, with their corresponding confidence intervals, for each variable in *varlist* or for all the variables in the data if *varlist* is not specified. `gmeans` and `hmeans` are synonyms for `ameans`.

If you simply want arithmetic means and corresponding confidence intervals, see [R] **ci**.

Options

Main

`add(#)` adds the value # to each variable in *varlist* before computing the means and confidence intervals. This option is useful when analyzing variables with nonpositive values.

`only` modifies the action of the `add(#)` option so that it adds # only to variables with at least one nonpositive value.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

Remarks

▷ Example 1

We have a dataset containing 8 observations on a variable named `x`. The eight values are 5, 4, −4, −5, 0, 0, *missing*, and 7.

```
. ameans x
```

Variable	Type	Obs	Mean	[95% Conf.	Interval]
x	Arithmetic	7	1	-3.204405	5.204405
	Geometric	3	5.192494	2.57899	10.45448
	Harmonic	3	5.060241	3.023008	15.5179

```
. ameans x, add(5)
```

Variable	Type	Obs	Mean	[95% Conf.	Interval]	
x	Arithmetic	7	6	1.795595	10.2044	*
	Geometric	6	5.477226	2.1096	14.22071	*
	Harmonic	6	3.540984	.	.	*

```
(*) 5 was added to the variables prior to calculating the results.
Missing values in confidence intervals for harmonic mean indicate
that confidence interval is undefined for corresponding variables.
Consult Reference Manual for details.
```

The number of observations displayed for the arithmetic mean is the number of nonmissing observations. The number of observations displayed for the geometric and harmonic means is the number of nonmissing, positive observations. Specifying the `add(5)` option produces 3 more positive observations. The confidence interval for the harmonic mean is not reported; see *Methods and formulas* below.

◁

Saved results

`ameans` saves the following in `r()`:

Scalars

`r(N)`	number of nonmissing observations; used for arithmetic mean
`r(N_pos)`	number of nonmissing positive observations; used for geometric and harmonic means
`r(mean)`	arithmetic mean
`r(lb)`	lower bound of confidence interval for arithmetic mean
`r(ub)`	upper bound of confidence interval for arithmetic mean
`r(Var)`	variance of untransformed data
`r(mean_g)`	geometric mean
`r(lb_g)`	lower bound of confidence interval for geometric mean
`r(ub_g)`	upper bound of confidence interval for geometric mean
`r(Var_g)`	variance of $\ln x_i$
`r(mean_h)`	harmonic mean
`r(lb_h)`	lower bound of confidence interval for harmonic mean
`r(ub_h)`	upper bound of confidence interval for harmonic mean
`r(Var_h)`	variance of $1/x_i$

Methods and formulas

`ameans` is implemented as an ado-file.

See Armitage, Berry, and Matthews (2002) or Snedecor and Cochran (1989). For a history of the concept of the mean, see Plackett (1958).

When restricted to the same set of values (that is, to positive values), the arithmetic mean ($\overline{x}$) is greater than or equal to the geometric mean, which in turn is greater than or equal to the harmonic mean. Equality holds only if all values within a sample are equal to a positive constant.

The arithmetic mean and its confidence interval are identical to those provided by `ci`; see [R] **ci**.

To compute the geometric mean, `ameans` first creates $u_j = \ln x_j$ for all positive x_j. The arithmetic mean of the u_j and its confidence interval are then computed as in `ci`. Let $\overline{u}$ be the resulting mean, and let $[\,L, U\,]$ be the corresponding confidence interval. The geometric mean is then $\exp(\overline{u})$, and its confidence interval is $[\,\exp(L), \exp(U)\,]$.

The same procedure is followed for the harmonic mean, except that then $u_j = 1/x_j$. The harmonic mean is then $1/\overline{u}$, and its confidence interval is $[\,1/U, 1/L\,]$ if L is greater than zero. If L is not greater than zero, this confidence interval is not defined, and missing values are reported.

When weights are specified, `ameans` applies the weights to the transformed values, $u_j = \ln x_j$ and $u_j = 1/x_j$, respectively, when computing the geometric and harmonic means. For details on how the weights are used to compute the mean and variance of the u_j, see [R] **summarize**. Without weights, the formula for the geometric mean reduces to

$$\exp\Big\{\frac{1}{n}\sum_j \ln(x_j)\Big\}$$

Without weights, the formula for the harmonic mean is

$$\frac{n}{\sum_j \frac{1}{x_j}}$$

Acknowledgments

This improved version of `ameans` is based on the `gmci` command (Carlin, Vidmar, and Ramalheira 1998) and was written by John Carlin, University of Melbourne, Australia; Suzanna Vidmar, University of Melbourne, Australia; and Carlos Ramalheira, Coimbra University Hospital, Portugal.

Title

anova — Analysis of variance and covariance

Syntax

`anova` *varname* [`termlist`] [*if*] [*in*] [*weight*] [`,` *options*]

where *termlist* is a factor-variable list (see [U] **11.4.3 Factor variables**) with the following additional features:

- Variables are assumed to be categorical; use the `c.` factor-variable operator to override this.
- The `|` symbol (indicating nesting) may be used in place of the `#` symbol (indicating interaction).
- The `/` symbol is allowed after a term and indicates that the following term is the error term for the preceding terms.

options	Description
Model	
`repeated(`*varlist*`)`	variables in *term*s that are repeated-measures variables
`partial`	use partial (or marginal) sums of squares
`sequential`	use sequential sums of squares
`noconstant`	suppress constant term
`dropemptycells`	drop empty cells from the design matrix
Adv. model	
`bse(`*term*`)`	between-subjects error term in repeated-measures ANOVA
`bseunit(`*varname*`)`	variable representing lowest unit in the between-subjects error term
`grouping(`*varname*`)`	grouping variable for computing pooled covariance matrix

`bootstrap`, `by`, `jackknife`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.
`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > ANOVA/MANOVA > Analysis of variance and covariance

Description

The `anova` command fits analysis-of-variance (ANOVA) and analysis-of-covariance (ANCOVA) models for balanced and unbalanced designs, including designs with missing cells; for repeated-measures ANOVA; and for factorial, nested, or mixed designs.

The `regress` command (see [R] **regress**) will display the coefficients, standard errors, etc., of the regression model underlying the last run of `anova`.

If you want to fit one-way ANOVA models, you may find the `oneway` or `loneway` command more convenient; see [R] **oneway** and [R] **loneway**. If you are interested in MANOVA or MANCOVA, see [MV] **manova**.

Options

Model

`repeated(`*varlist*`)` indicates the names of the categorical variables in the *term*s that are to be treated as repeated-measures variables in a repeated-measures ANOVA or ANCOVA.

`partial` presents the ANOVA table using partial (or marginal) sums of squares. This setting is the default. Also see the `sequential` option.

`sequential` presents the ANOVA table using sequential sums of squares.

`noconstant` suppresses the constant term (intercept) from the ANOVA or regression model.

`dropemptycells` drops empty cells from the design matrix. If `c(emptycells)` is set to `keep` (see [R] **set emptycells**), this option temporarily resets it to `drop` before running the ANOVA model. If `c(emptycells)` is already set to `drop`, this option does nothing.

Adv. model

`bse(`*term*`)` indicates the between-subjects error term in a repeated-measures ANOVA. This option is needed only in the rare case when the `anova` command cannot automatically determine the between-subjects error term.

`bseunit(`*varname*`)` indicates the variable representing the lowest unit in the between-subjects error term in a repeated-measures ANOVA. This option is rarely needed because the `anova` command automatically selects the first variable listed in the between-subjects error term as the default for this option.

`grouping(`*varname*`)` indicates a variable that determines which observations are grouped together in computing the covariance matrices that will be pooled and used in a repeated-measures ANOVA. This option is rarely needed because the `anova` command automatically selects the combination of all variables except the first (or as specified in the `bseunit()` option) in the between-subjects error term as the default for grouping observations.

Remarks

Remarks are presented under the following headings:

Introduction
One-way ANOVA
Two-way ANOVA
N-way ANOVA
Weighted data
ANCOVA
Nested designs
Mixed designs
Latin-square designs
Repeated-measures ANOVA

Introduction

`anova` uses least squares to fit the linear models known as ANOVA or ANCOVA (henceforth referred to simply as ANOVA models).

If your interest is in one-way ANOVA, you may find the `oneway` command to be more convenient; see [R] **oneway**.

Structural equation modeling provides a more general framework for fitting ANOVA models; see the *Stata Structural Equation Modeling Reference Manual*.

ANOVA was pioneered by Fisher. It features prominently in his texts on statistical methods and his design of experiments (1925, 1935). Many books discuss ANOVA; see, for instance, Altman (1991); van Belle et al. (2004); Cobb (1998); Snedecor and Cochran (1989); or Winer, Brown, and Michels (1991). For a classic source, see Scheffé (1959). Kennedy and Gentle (1980) discuss ANOVA's computing problems. Edwards (1985) is concerned primarily with the relationship between multiple regression and ANOVA. Acock (2010, chap. 9) illustrates his discussion with Stata output. Repeated-measures ANOVA is discussed in Winer, Brown, and Michels (1991); Kuehl (2000); and Milliken and Johnson (2009). Pioneering work in repeated-measures ANOVA can be found in Box (1954); Geisser and Greenhouse (1958); Huynh and Feldt (1976); and Huynh (1978).

One-way ANOVA

`anova`, entered without options, performs and reports standard ANOVA. For instance, to perform a one-way layout of a variable called `endog` on `exog`, you would type `anova endog exog`.

▷ Example 1

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following data:

```
. use http://www.stata-press.com/data/r12/apple
(Apple trees)
. list, abbrev(10) sepby(treatment)
```

	treatment	weight
1.	1	117.5
2.	1	113.8
3.	1	104.4
4.	2	48.9
5.	2	50.4
6.	2	58.9
7.	3	70.4
8.	3	86.9
9.	4	87.7
10.	4	67.3

To obtain one-way ANOVA results, we type

```
. anova weight treatment
                          Number of obs =      10     R-squared     =  0.9147
                          Root MSE      = 9.07002     Adj R-squared =  0.8721

                   Source | Partial SS    df       MS           F     Prob > F
--------------------------+----------------------------------------------------
                    Model |  5295.54433     3  1765.18144       21.46     0.0013
                          |
                treatment |  5295.54433     3  1765.18144       21.46     0.0013
                          |
                 Residual |  493.591667     6  82.2652778
--------------------------+----------------------------------------------------
                    Total |    5789.136     9  643.237333
```

We find significant (at better than the 1% level) differences among the four concentrations.

Although the output is a usual ANOVA table, let's run through it anyway. Above the table is a summary of the underlying regression. The model was fit on 10 observations, and the root mean squared error (`Root MSE`) is 9.07. The R^2 for the model is 0.9147, and the adjusted R^2 is 0.8721.

The first line of the table summarizes the model. The sum of squares (`Partial SS`) for the model is 5295.5 with 3 degrees of freedom (`df`). This line results in a mean square (`MS`) of $5295.5/3 \approx 1765.2$. The corresponding F statistic is 21.46 and has a significance level of 0.0013. Thus the model appears to be significant at the 0.13% level.

The next line summarizes the first (and only) term in the model, `treatment`. Because there is only one term, the line is identical to that for the overall model.

The third line summarizes the residual. The residual sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27. The square root of this latter number is reported as the `Root MSE`.

The model plus the residual sum of squares equals the total sum of squares, which is reported as 5789.1 in the last line of the table. This is the total sum of squares of `weight` after removal of the mean. Similarly, the model plus the residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.

◁

❑ Technical note

Rather than using the `anova` command, we could have performed this analysis by using the `oneway` command. Example 1 in [R] **oneway** repeats this same analysis. You may wish to compare the output.

❑

Type `regress` to see the underlying regression model corresponding to an ANOVA model fit using the `anova` command.

▷ Example 2

Returning to the apple tree experiment, we found that the fertilizer concentration appears to significantly affect the average weight of the fruit. Although that finding is interesting, we next want to know which concentration appears to grow the heaviest fruit. One way to find out is by examining the underlying regression coefficients.

```
. regress, baselevels
      Source |       SS       df       MS              Number of obs =      10
-------------+------------------------------           F(  3,     6) =   21.46
       Model |  5295.54433     3  1765.18144            Prob > F      =  0.0013
    Residual |  493.591667     6  82.2652778            R-squared     =  0.9147
-------------+------------------------------           Adj R-squared =  0.8721
       Total |    5789.136     9  643.237333            Root MSE      =    9.07

------------------------------------------------------------------------------
      weight |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   treatment |
           1 |          0  (base)
           2 |  -59.16667   7.405641    -7.99   0.000    -77.28762   -41.04572
           3 |     -33.25   8.279758    -4.02   0.007    -53.50984   -12.99016
           4 |      -34.4   8.279758    -4.15   0.006    -54.65984   -14.14016
             |
       _cons |      111.9   5.236579    21.37   0.000     99.08655    124.7134
------------------------------------------------------------------------------
```

See [R] **regress** for an explanation of how to read this table. The `baselevels` option of `regress` displays a row indicating the base category for our categorical variable, `treatment`. In summary, we find that concentration 1, the base (omitted) group, produces significantly heavier fruits than concentration 2, 3, and 4; concentration 2 produces the lightest fruits; and concentrations 3 and 4 appear to be roughly equivalent.

◁

▷ Example 3

We previously typed `anova weight treatment` to produce and display the ANOVA table for our apple tree experiment. Typing `regress` displays the regression coefficients. We can redisplay the ANOVA table by typing `anova` without arguments:

```
. anova
                           Number of obs =      10     R-squared     =  0.9147
                           Root MSE      = 9.07002     Adj R-squared =  0.8721

                  Source | Partial SS    df       MS           F     Prob > F
-------------------------+------------------------------------------------------
                   Model |  5295.54433     3  1765.18144       21.46     0.0013
                         |
               treatment |  5295.54433     3  1765.18144       21.46     0.0013
                         |
                Residual |  493.591667     6  82.2652778
-------------------------+------------------------------------------------------
                   Total |    5789.136     9  643.237333
```

◁

Two-way ANOVA

You can include multiple explanatory variables with the `anova` command, and you can specify interactions by placing '`#`' between the variable names. For instance, typing `anova y a b` performs a two-way layout of `y` on `a` and `b`. Typing `anova y a b a#b` performs a full two-way factorial layout. The shorthand `anova y a##b` does the same.

With the default partial sums of squares, when you specify interacted terms, the order of the terms does not matter. Typing `anova y a b a#b` is the same as typing `anova y b a b#a`.

▷ Example 4

The classic two-way factorial ANOVA problem, at least as far as computer manuals are concerned, is a two-way ANOVA design from Afifi and Azen (1979).

Fifty-eight patients, each suffering from one of three different diseases, were randomly assigned to one of four different drug treatments, and the change in their systolic blood pressure was recorded. Here are the data:

	Disease 1	Disease 2	Disease 3
Drug 1	42, 44, 36 13, 19, 22	33, 26, 33 21	31, –3, 25 25, 24
Drug 2	28, 23, 34 42, 13	34, 33, 31 36	3, 26, 28 32, 4, 16
Drug 3	1, 29, 19	11, 9, 7 1, –6	21, 1, 9 3
Drug 4	24, 9, 22 –2, 15	27, 12, 12 –5, 16, 15	22, 7, 25 5, 12

Let's assume that we have entered these data into Stata and stored the data as `systolic.dta`. Below we `use` the data, `list` the first 10 observations, `summarize` the variables, and `tabulate` the control variables:

```
. use http://www.stata-press.com/data/r12/systolic
(Systolic Blood Pressure Data)
. list in 1/10
```

	drug	disease	systolic
1.	1	1	42
2.	1	1	44
3.	1	1	36
4.	1	1	13
5.	1	1	19
6.	1	1	22
7.	1	2	33
8.	1	2	26
9.	1	2	33
10.	1	2	21

```
. summarize
```

Variable	Obs	Mean	Std. Dev.	Min	Max
drug	58	2.5	1.158493	1	4
disease	58	2.017241	.8269873	1	3
systolic	58	18.87931	12.80087	-6	44

```
. tabulate drug disease
```

	Patient's Disease			
Drug Used	1	2	3	Total
1	6	4	5	15
2	5	4	6	15
3	3	5	4	12
4	5	6	5	16
Total	19	19	20	58

Each observation in our data corresponds to one patient, and for each patient we record `drug`, `disease`, and the increase in the systolic blood pressure, `systolic`. The tabulation reveals that the data are not balanced—there are not equal numbers of patients in each `drug`–`disease` cell. Stata does not require that the data be balanced. We can perform a two-way factorial ANOVA by typing

```
. anova systolic drug disease drug#disease
```

```
                   Number of obs =      58     R-squared     =  0.4560
                   Root MSE      = 10.5096     Adj R-squared =  0.3259
```

Source	Partial SS	df	MS	F	Prob > F
Model	4259.33851	11	387.212591	3.51	0.0013
drug	2997.47186	3	999.157287	9.05	0.0001
disease	415.873046	2	207.936523	1.88	0.1637
drug#disease	707.266259	6	117.87771	1.07	0.3958
Residual	5080.81667	46	110.452536		
Total	9340.15517	57	163.862371		

Although Stata's `table` command does not perform ANOVA, it can produce useful summary tables of your data (see [R] **table**):

```
. table drug disease, c(mean systolic) row col f(%8.2f)
```

Drug Used	Patient's Disease 1	2	3	Total
1	29.33	28.25	20.40	26.07
2	28.00	33.50	18.17	25.53
3	16.33	4.40	8.50	8.75
4	13.60	12.83	14.20	13.50
Total	22.79	18.21	15.80	18.88

These are simple means and are not influenced by our `anova` model. More useful is the `margins` command (see [R] **margins**) that provides marginal means and adjusted predictions. Because `drug` is the only significant factor in our ANOVA, we now examine the adjusted marginal means for `drug`.

```
. margins drug, asbalanced
Adjusted predictions                            Number of obs   =         58
Expression   : Linear prediction, predict()
at           : drug             (asbalanced)
               disease          (asbalanced)
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
drug						
1	25.99444	2.751008	9.45	0.000	20.60257	31.38632
2	26.55556	2.751008	9.65	0.000	21.16368	31.94743
3	9.744444	3.100558	3.14	0.002	3.667462	15.82143
4	13.54444	2.637123	5.14	0.000	8.375778	18.71311

These adjusted marginal predictions are not equal to the simple drug means (see the total column from the `table` command); they are based upon predictions from our ANOVA model. The `asbalanced` option of `margins` corresponds with the interpretation of the F statistic produced by ANOVA—each cell is given equal weight regardless of its sample size (see the following three technical notes). You

can omit the asbalanced option and obtain predictive margins that take into account the unequal sample sizes of the cells.

```
. margins drug
Predictive margins                              Number of obs   =         58
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
drug						
1	25.89799	2.750533	9.42	0.000	20.50704	31.28893
2	26.41092	2.742762	9.63	0.000	21.0352	31.78664
3	9.722989	3.099185	3.14	0.002	3.648697	15.79728
4	13.55575	2.640602	5.13	0.000	8.380261	18.73123

◁

❑ Technical note

How do you interpret the significance of terms like drug and disease in unbalanced data? If you are familiar with SAS, the sums of squares and the F statistic reported by Stata correspond to SAS type III sums of squares. (Stata can also calculate sequential sums of squares, but we will postpone that topic for now.)

Let's think in terms of the following table:

	Disease 1	Disease 2	Disease 3	
Drug 1	μ_{11}	μ_{12}	μ_{13}	$\mu_{1\cdot}$
Drug 2	μ_{21}	μ_{22}	μ_{23}	$\mu_{2\cdot}$
Drug 3	μ_{31}	μ_{32}	μ_{33}	$\mu_{3\cdot}$
Drug 4	μ_{41}	μ_{42}	μ_{43}	$\mu_{4\cdot}$
	$\mu_{\cdot 1}$	$\mu_{\cdot 2}$	$\mu_{\cdot 3}$	$\mu_{\cdot\cdot}$

In this table, μ_{ij} is the mean increase in systolic blood pressure associated with drug i and disease j, while $\mu_{i\cdot}$ is the mean for drug i, $\mu_{\cdot j}$ is the mean for disease j, and $\mu_{\cdot\cdot}$ is the overall mean.

If the data are balanced, meaning that there are equal numbers of observations going into the calculation of each mean μ_{ij}, the row means, $\mu_{i\cdot}$, are given by

$$\mu_{i\cdot} = \frac{\mu_{i1} + \mu_{i2} + \mu_{i3}}{3}$$

In our case, the data are not balanced, but we define the $\mu_{i\cdot}$ according to that formula anyway. The test for the main effect of drug is the test that

$$\mu_{1\cdot} = \mu_{2\cdot} = \mu_{3\cdot} = \mu_{4\cdot}$$

To be absolutely clear, the F test of the term drug, called the *main effect* of drug, is formally equivalent to the test of the three constraints:

$$\frac{\mu_{11}+\mu_{12}+\mu_{13}}{3} = \frac{\mu_{21}+\mu_{22}+\mu_{23}}{3}$$

$$\frac{\mu_{11}+\mu_{12}+\mu_{13}}{3} = \frac{\mu_{31}+\mu_{32}+\mu_{33}}{3}$$

$$\frac{\mu_{11}+\mu_{12}+\mu_{13}}{3} = \frac{\mu_{41}+\mu_{42}+\mu_{43}}{3}$$

In our data, we obtain a significant F statistic of 9.05 and thus reject those constraints.

❑

❑ Technical note

Stata can display the symbolic form underlying the test statistics it presents, as well as display other test statistics and their symbolic forms; see *Obtaining symbolic forms* in [R] **anova postestimation**. Here is the result of requesting the symbolic form for the main effect of `drug` in our data:

```
. test drug, symbolic
drug
           1  -(r2+r3+r4)
           2   r2
           3   r3
           4   r4
disease
           1  0
           2  0
           3  0
drug#disease
        1  1  -1/3 (r2+r3+r4)
        1  2  -1/3 (r2+r3+r4)
        1  3  -1/3 (r2+r3+r4)
        2  1   1/3 r2
        2  2   1/3 r2
        2  3   1/3 r2
        3  1   1/3 r3
        3  2   1/3 r3
        3  3   1/3 r3
        4  1   1/3 r4
        4  2   1/3 r4
        4  3   1/3 r4
_cons          0
```

This says exactly what we said in the previous technical note.

❑

❑ Technical note

Saying that there is no main effect of a variable is not the same as saying that it has no effect at all. Stata's ability to perform ANOVA on unbalanced data can easily be put to ill use.

For example, consider the following table of the probability of surviving a bout with one of two diseases according to the drug administered to you:

	Disease 1	Disease 2
Drug 1	1	0
Drug 2	0	1

If you have disease 1 and are administered drug 1, you live. If you have disease 2 and are administered drug 2, you live. In all other cases, you die.

This table has no main effects of either drug or disease, although there is a large interaction effect. You might now be tempted to reason that because there is only an interaction effect, you would be indifferent between the two drugs in the absence of knowledge about which disease infects you. Given an equal chance of having either disease, you reason that it does not matter which drug is administered to you—either way, your chances of surviving are 0.5.

You may not, however, have an equal chance of having either disease. If you knew that disease 1 was 100 times more likely to occur in the population, and if you knew that you had one of the two diseases, you would express a strong preference for receiving drug 1.

When you calculate the significance of main effects on unbalanced data, you must ask yourself why the data are unbalanced. If the data are unbalanced for random reasons and you are making predictions for a balanced population, the test of the main effect makes perfect sense. If, however, the data are unbalanced because the underlying populations are unbalanced and you are making predictions for such unbalanced populations, the test of the main effect may be practically—if not statistically—meaningless.

❑

▷ Example 5

Stata can perform ANOVA not only on unbalanced populations, but also on populations that are so unbalanced that entire cells are missing. For instance, using our systolic blood pressure data, let's refit the model eliminating the drug 1–disease 1 cell. Because `anova` follows the same syntax as all other Stata commands, we can explicitly specify the data to be used by typing the `if` qualifier at the end of the `anova` command. Here we want to use the data that are not for drug 1 and disease 1:

```
. anova systolic drug##disease if !(drug==1 & disease==1)
                          Number of obs =      52     R-squared     =  0.4545
                          Root MSE      = 10.1615     Adj R-squared =  0.3215
                 Source | Partial SS    df       MS           F     Prob > F
------------------------+----------------------------------------------------
                  Model |  3527.95897    10  352.795897        3.42     0.0025
                        |
                   drug |  2686.57832     3  895.526107        8.67     0.0001
                disease |  327.792598     2  163.896299        1.59     0.2168
           drug#disease |  703.007602     5   140.60152        1.36     0.2586
                        |
               Residual |  4233.48333    41  103.255691
------------------------+----------------------------------------------------
                  Total |  7761.44231    51  152.185143
```

Here we used `drug##disease` as a shorthand for `drug disease drug#disease`.

◁

❑ Technical note

The test of the main effect of drug in the presence of missing cells is more complicated than that for unbalanced data. Our underlying tableau now has the following form:

	Disease 1	Disease 2	Disease 3	
Drug 1		μ_{12}	μ_{13}	
Drug 2	μ_{21}	μ_{22}	μ_{23}	$\mu_{2\cdot}$
Drug 3	μ_{31}	μ_{32}	μ_{33}	$\mu_{3\cdot}$
Drug 4	μ_{41}	μ_{42}	μ_{43}	$\mu_{4\cdot}$
		$\mu_{\cdot 2}$	$\mu_{\cdot 3}$	

The hole in the drug 1–disease 1 cell indicates that the mean is unobserved. Considering the main effect of drug, the test is unchanged for the rows in which all the cells are defined:

$$\mu_{2\cdot} = \mu_{3\cdot} = \mu_{4\cdot}$$

The first row, however, requires special attention. Here we want the average outcome for drug 1, which is averaged only over diseases 2 and 3, to be equal to the average values of all other drugs averaged over those same two diseases:

$$\frac{\mu_{12} + \mu_{13}}{2} = \frac{\big(\mu_{22} + \mu_{23}\big)/2 + \big(\mu_{32} + \mu_{33}\big)/2 + \big(\mu_{42} + \mu_{43}\big)/2}{3}$$

Thus the test contains three constraints:

$$\begin{aligned}
\frac{\mu_{21} + \mu_{22} + \mu_{23}}{3} &= \frac{\mu_{31} + \mu_{32} + \mu_{33}}{3} \\
\frac{\mu_{21} + \mu_{22} + \mu_{23}}{3} &= \frac{\mu_{41} + \mu_{42} + \mu_{43}}{3} \\
\frac{\mu_{12} + \mu_{13}}{2} &= \frac{\mu_{22} + \mu_{23} + \mu_{32} + \mu_{33} + \mu_{42} + \mu_{43}}{6}
\end{aligned}$$

❑

Stata can calculate two types of sums of squares, *partial* and *sequential*. If you do not specify which sums of squares to calculate, Stata calculates partial sums of squares. The technical notes above have gone into great detail about the definition and use of partial sums of squares. Use the `sequential` option to obtain sequential sums of squares.

❑ Technical note

Before we illustrate sequential sums of squares, consider one more feature of the partial sums. If you know how such things are calculated, you may worry that the terms must be specified in some particular order, that Stata would balk or, even worse, produce different results if you typed, say, `anova drug#disease drug disease` rather than `anova drug disease drug#disease`. We assure you that is not the case.

When you type a model, Stata internally reorganizes the terms, forms the cross-product matrix, inverts it, converts the result to an upper-Hermite form, and then performs the hypothesis tests. As a final touch, Stata reports the results in the same order that you typed the terms.

❑

▷ Example 6

We wish to estimate the effects on systolic blood pressure of drug and disease by using sequential sums of squares. We want to introduce disease first, then drug, and finally, the interaction of drug and disease:

```
. anova systolic disease drug disease#drug, sequential
                          Number of obs =      58     R-squared     =  0.4560
                          Root MSE      = 10.5096     Adj R-squared =  0.3259
```

Source	Seq. SS	df	MS	F	Prob > F
Model	4259.33851	11	387.212591	3.51	0.0013
disease	488.639383	2	244.319691	2.21	0.1210
drug	3063.43286	3	1021.14429	9.25	0.0001
disease#drug	707.266259	6	117.87771	1.07	0.3958
Residual	5080.81667	46	110.452536		
Total	9340.15517	57	163.862371		

The F statistic on `disease` is now 2.21. When we fit this same model by using partial sums of squares, the statistic was 1.88.

◁

N-way ANOVA

You may include high-order interaction terms, such as a third-order interaction between the variables `A`, `B`, and `C`, by typing `A#B#C`.

▷ Example 7

We wish to determine the operating conditions that maximize yield for a manufacturing process. There are three temperature settings, two chemical supply companies, and two mixing methods under investigation. Three observations are obtained for each combination of these three factors.

```
. use http://www.stata-press.com/data/r12/manuf
(manufacturing process data)
. describe
Contains data from http://www.stata-press.com/data/r12/manuf.dta
  obs:            36                          manufacturing process data
 vars:             4                          2 Jan 2011 13:28
 size:           144
```

variable name	storage type	display format	value label	variable label
temperature	byte	%9.0g	temp	machine temperature setting
chemical	byte	%9.0g	supplier	chemical supplier
method	byte	%9.0g	meth	mixing method
yield	byte	%9.0g		product yield

```
Sorted by:
```

We wish to perform a three-way factorial ANOVA. We could type

```
. anova yield temp chem temp#chem meth temp#meth chem#meth temp#chem#meth
```

but prefer to use the ## factor-variable operator for brevity.

```
. anova yield temp##chem##meth
```

```
                          Number of obs =      36     R-squared     =  0.5474
                          Root MSE      = 2.62996     Adj R-squared =  0.3399
```

Source	Partial SS	df	MS	F	Prob > F
Model	200.75	11	18.25	2.64	0.0227
temperature	30.5	2	15.25	2.20	0.1321
chemical	12.25	1	12.25	1.77	0.1958
temperature#chemical	24.5	2	12.25	1.77	0.1917
method	42.25	1	42.25	6.11	0.0209
temperature#method	87.5	2	43.75	6.33	0.0062
chemical#method	.25	1	.25	0.04	0.8508
temperature#chemical# method	3.5	2	1.75	0.25	0.7785
Residual	166	24	6.91666667		
Total	366.75	35	10.4785714		

The interaction between temperature and method appears to be the important story in these data. A table of means for this interaction is given below.

```
. table method temp, c(mean yield) row col f(%8.2f)
```

mixing method	machine temperature setting low	medium	high	Total
stir	7.50	6.00	6.00	6.50
fold	5.50	9.00	11.50	8.67
Total	6.50	7.50	8.75	7.58

Here our ANOVA is balanced (each cell has the same number of observations), and we obtain the same values as in the table above (but with additional information such as confidence intervals) by using the `margins` command. Because our ANOVA is balanced, using the `asbalanced` option with `margins` would not produce different results. We request the predictive margins for the two terms that appear significant in our ANOVA: `temperature#method` and `method`.

```
. margins temperature#method method
Predictive margins                                Number of obs   =         36
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
temperature# method						
1 1	7.5	1.073675	6.99	0.000	5.395636	9.604364
1 2	5.5	1.073675	5.12	0.000	3.395636	7.604364
2 1	6	1.073675	5.59	0.000	3.895636	8.104364
2 2	9	1.073675	8.38	0.000	6.895636	11.10436
3 1	6	1.073675	5.59	0.000	3.895636	8.104364
3 2	11.5	1.073675	10.71	0.000	9.395636	13.60436
method						
1	6.5	.6198865	10.49	0.000	5.285045	7.714955
2	8.666667	.6198865	13.98	0.000	7.451711	9.881622

We decide to use the folding method of mixing and a high temperature in our manufacturing process.

◁

Weighted data

Like all estimation commands, `anova` can produce estimates on weighted data. See [U] **11.1.6 weight** for details on specifying the weight.

▷ Example 8

We wish to investigate the prevalence of byssinosis, a form of pneumoconiosis that can afflict workers exposed to cotton dust. We have data on 5,419 workers in a large cotton mill. We know whether each worker smokes, his or her race, and the dustiness of the work area. The variables are

`smokes`	smoker or nonsmoker in the last five years
`race`	white or other
`workplace`	1 (most dusty), 2 (less dusty), 3 (least dusty)

We wish to fit an ANOVA model explaining the prevalence of byssinosis according to a full factorial model of `smokes`, `race`, and `workplace`.

The data are unbalanced. Moreover, although we have data on 5,419 workers, the data are grouped according to the explanatory variables, along with some other variables, resulting in 72 observations. For each observation, we know the number of workers in the group (`pop`), the prevalence of byssinosis (`prob`), and the values of the three explanatory variables. Thus we wish to fit a three-way factorial model on grouped data.

We begin by showing a bit of the data, which are from Higgins and Koch (1977).

```
. use http://www.stata-press.com/data/r12/byssin
(Byssinosis incidence)
. describe
Contains data from http://www.stata-press.com/data/r12/byssin.dta
  obs:            72                          Byssinosis incidence
 vars:             5                          19 Dec 2010 07:04
 size:           864
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
smokes          int    %8.0g       smokes     Smokes
race            int    %8.0g       race       Race
workplace       int    %8.0g       workplace
                                               Dustiness of workplace
pop             int    %8.0g                  Population size
prob            float  %9.0g                  Prevalence of byssinosis
-------------------------------------------------------------------------------
Sorted by:
. list in 1/5, abbrev(10) divider
```

	smokes	race	workplace	pop	prob
1.	yes	white	most	40	.075
2.	yes	white	less	74	0
3.	yes	white	least	260	.0076923
4.	yes	other	most	164	.152439
5.	yes	other	less	88	0

The first observation in the data represents a group of 40 white workers who smoke and work in a "most" dusty work area. Of those 40 workers, 7.5% have byssinosis. The second observation represents a group of 74 white workers who also smoke but who work in a "less" dusty environment. None of those workers has byssinosis.

Almost every Stata command allows weights. Here we want to weight the data by `pop`. We can, for instance, make a table of the number of workers by their smoking status and race:

```
. tabulate smokes race [fw=pop]
```

	Race		
Smokes	other	white	Total
no	799	1,431	2,230
yes	1,104	2,085	3,189
Total	1,903	3,516	5,419

The `[fw=pop]` at the end of the `tabulate` command tells Stata to count each observation as representing `pop` persons. When making the tally, `tabulate` treats the first observation as representing 40 workers, the second as representing 74 workers, and so on.

Similarly, we can make a table of the dustiness of the workplace:

```
. tabulate workplace [fw=pop]
```

Dustiness of workplace	Freq.	Percent	Cum.
least	3,450	63.66	63.66
less	1,300	23.99	87.65
most	669	12.35	100.00
Total	5,419	100.00	

We can discover the average incidence of byssinosis among these workers by typing

```
. summarize prob [fw=pop]
```

Variable	Obs	Mean	Std. Dev.	Min	Max
prob	5419	.0304484	.0567373	0	.287037

We discover that 3.04% of these workers have byssinosis. Across all cells, the byssinosis rates vary from 0 to 28.7%. Just to prove that there might be something here, let's obtain the average incidence rates according to the dustiness of the workplace:

```
. table workplace smokes race [fw=pop], c(mean prob)
```

Dustiness of workplace	Race and Smokes			
	other		white	
	no	yes	no	yes
least	.0107527	.0101523	.0081549	.0162774
less	.02	.0081633	.0136612	.0143149
most	.0820896	.1679105	.0833333	.2295082

Let's now fit the ANOVA model.

```
. anova prob workplace smokes race workplace#smokes workplace#race
> smokes#race workplace#smokes#race [aweight=pop]
(sum of wgt is   5.4190e+03)
```

Number of obs = 65 R-squared = 0.8300
Root MSE = .025902 Adj R-squared = 0.7948

Source	Partial SS	df	MS	F	Prob > F

Smoking combined with the most dusty workplace produces the highest byssinosis rates.

◁

Ronald Aylmer Fisher (1890–1962) (Sir Ronald from 1952) studied mathematics at Cambridge. Even before he finished his studies, he had published on statistics. He worked as a statistician at Rothamsted Experimental Station (1919–1933), as professor of eugenics at University College London (1933–1943), as professor of genetics at Cambridge (1943–1957), and in retirement at the CSIRO Division of Mathematical Statistics in Adelaide. His many fundamental and applied contributions to statistics and genetics mark him as one of the greatest statisticians of all time, including original work on tests of significance, distribution theory, theory of estimation, fiducial inference, and design of experiments.

ANCOVA

You can include multiple explanatory variables with the `anova` command, but unless you explicitly state otherwise by using the `c.` factor-variable operator, all the variables are interpreted as *categorical variables*. Using the `c.` operator, you can designate variables as *continuous* and thus perform ANCOVA.

▷ Example 9

We have census data recording the death rate (`drate`) and median age (`age`) for each state. The dataset also includes the region of the country in which each state is located (`region`):

```
. use http://www.stata-press.com/data/r12/census2
(1980 Census data by state)
. summarize drate age region
```

Variable	Obs	Mean	Std. Dev.	Min	Max
drate	50	84.3	13.07318	40	107
age	50	29.5	1.752549	24	35
region	50	2.66	1.061574	1	4

`age` is coded in integral years from 24 to 35, and `region` is coded from 1 to 4, with 1 standing for the Northeast, 2 for the North Central, 3 for the South, and 4 for the West.

When we examine the data more closely, we discover large differences in the death rate across regions of the country:

```
. tabulate region, summarize(drate)
```

Census region	Summary of Death Rate Mean	Std. Dev.	Freq.
NE	93.444444	7.0553368	9
N Cntrl	88.916667	5.5833899	12
South	88.3125	8.5457104	16
West	68.769231	13.342625	13
Total	84.3	13.073185	50

Naturally, we wonder if these differences might not be explained by differences in the median ages of the populations. To find out, we fit a regression model (via `anova`) of `drate` on `region` and `age`. In the `anova` example below, we treat `age` as a categorical variable.

```
. anova drate region age
```

```
                   Number of obs =      50     R-squared     =  0.7927
                   Root MSE      =  6.7583     Adj R-squared =  0.7328
```

Source	Partial SS	df	MS	F	Prob > F
Model	6638.86529	11	603.533208	13.21	0.0000
region	1320.00973	3	440.003244	9.63	0.0001
age	2237.24937	8	279.656171	6.12	0.0000
Residual	1735.63471	38	45.6745977		
Total	8374.5	49	170.908163		

We have the answer to our question: differences in median ages do not eliminate the differences in death rates across the four regions. The ANOVA table summarizes the two terms in the model, `region` and `age`. The `region` term contains 3 degrees of freedom, and the `age` term contains 8 degrees of freedom. Both are significant at better than the 1% level.

The `age` term contains 8 degrees of freedom. Because we did not explicitly indicate that `age` was to be treated as a continuous variable, it was treated as *categorical*, meaning that unique coefficients were estimated for each level of age. The only clue of this labeling is that the number of degrees of freedom associated with the `age` term exceeds 1. The labeling becomes more obvious if we review the regression coefficients:

```
. regress, baselevels
```

Source	SS	df	MS

```

Although we started analyzing these data to explain the regional differences in death rate, let's focus on the effect of age for a moment. In our first model, each level of `age` had a unique death rate associated with it. For instance, the predicted death rate in a north central state with a median age of 28 was

$$0.44 + 12.66 + 68.37 \approx 81.47$$

whereas the predicted death rate from our current model is

$$1.79 + 3.92 \times 28 - 28.60 \approx 82.95$$

Our previous model had an R^2 of 0.7927, whereas our current model has an R^2 of 0.7203. This "small" loss of predictive power accompanies a gain of 7 degrees of freedom, so we suspect that the continuous-age model is as good as the discrete-age model.

◁

❑ Technical note

There is enough information in the two ANOVA tables to attach a statistical significance to our suspicion that the loss of predictive power is offset by the savings in degrees of freedom. Because the continuous-age model is nested within the discrete-age model, we can perform a standard Chow test. For those of us who know such formulas off the top of our heads, the F statistic is

$$\frac{(2342.41746 - 1735.63471)/7}{45.6745977} = 1.90$$

There is, however, a better way.

We can find out whether our continuous model is as good as our discrete model by putting `age` in the model twice: once as a continuous variable and once as a categorical variable. The categorical variable will then measure deviations around the straight line implied by the continuous variable, and the F test for the significance of the categorical variable will test whether those deviations are jointly zero.

```
. anova drate region c.age age
                          Number of obs =      50     R-squared     =  0.7927
                          Root MSE      =  6.7583     Adj R-squared =  0.7328
```

Source	Partial SS	df	MS	F	Prob > F
Model	6638.86529	11	603.533208	13.21	0.0000
region	1320.00973	3	440.003244	9.63	0.0001
age	699.74137	1	699.74137	15.32	0.0004
age	606.782747	7	86.6832496	1.90	0.0970
Residual	1735.63471	38	45.6745977		
Total	8374.5	49	170.908163		

We find that the F test for the significance of the (categorical) `age` variable is 1.90, just as we calculated above. It is significant at the 9.7% level. If we hold to a 5% significance level, we cannot reject the null hypothesis that the effect of `age` is linear.

❑

▷ Example 10

In our census data, we still find significant differences across the regions after controlling for the median age of the population. We might now wonder whether the regional differences are differences in level—independent of age—or are instead differences in the regional effects of age. Just as we can interact categorical variables with other categorical variables, we can interact categorical variables with continuous variables.

```
. anova drate region c.age region#c.age
                          Number of obs =      50     R-squared     =  0.7365
                          Root MSE      = 7.24852     Adj R-squared =  0.6926
```

Source	Partial SS	df	MS	F	Prob > F
Model	6167.7737	7	881.110529	16.77	0.0000
region	188.713602	3	62.9045339	1.20	0.3225
age	873.425599	1	873.425599	16.62	0.0002
region#age	135.691162	3	45.2303874	0.86	0.4689
Residual	2206.7263	42	52.5411023		
Total	8374.5	49	170.908163		

The `region#c.age` term in our model measures the differences in slopes across the regions. We cannot reject the null hypothesis that there are no such differences. The `region` effect is now "insignificant". This status does not mean that there are no regional differences in death rates because each test is a *marginal* or *partial* test. Here, with `region#c.age` included in the model, `region` is being tested at the point where `age` is zero. Apart from this value not existing in the dataset, it is also a long way from the mean value of `age`, so the test of `region` at this point is meaningless (although it is valid if you acknowledge what is being tested).

To obtain a more sensible test of `region`, we can subtract the mean from the `age` variable and use this in the model.

```
. quietly summarize age
. generate mage = age - r(mean)
```

```
. anova drate region c.mage region#c.mage
                          Number of obs =      50     R-squared     =  0.7365
                          Root MSE      = 7.24852     Adj R-squared =  0.6926
```

Source	Partial SS	df	MS	F	Prob > F
Model	6167.7737	7	881.110529	16.77	0.0000
region	1166.14735	3	388.715783	7.40	0.0004
mage	873.425599	1	873.425599	16.62	0.0002

Residual	2206.7263	42	52.5411023		
Total	8374.5	49	170.908163		

`region` is significant when tested at the mean of the `age` variable.

◁

Remember that we can specify interactions by typing *varname*`#`*varname*. We have seen examples of interacting categorical variables with categorical variables and, in the examples above, a categorical variable (`region`) with a continuous variable (`age` or `mage`).

We can also interact continuous variables with continuous variables. To include an $\texttt{age}^2$ term in our model, we could type `c.age#c.age`. If we also wanted to interact the categorical variable `region` with the $\texttt{age}^2$ term, we could type `region#c.age#c.age` (or even `c.age#region#c.age`).

Nested designs

In addition to specifying interaction terms, nested terms can also be specified in an ANOVA. A vertical bar is used to indicate nesting: `A|B` is read as `A` nested within `B`. `A|B|C` is read as `A` nested within `B`, which is nested within `C`. `A|B#C` is read as `A` is nested within the interaction of `B` and `C`. `A#B|C` is read as the interaction of `A` and `B`, which is nested within `C`.

Different error terms can be specified for different parts of the model. The forward slash is used to indicate that the next term in the model is the error term for what precedes it. For instance, `anova y A / B|A` indicates that the F test for `A` is to be tested by using the mean square from `B|A` in the denominator. Error terms (terms following the slash) are generally not tested unless they are themselves followed by a slash. Residual error is the default error term.

For example, consider *A* `/` *B* `/` *C*, where *A*, *B*, and *C* may be arbitrarily complex terms. Then `anova` will report *A* tested by *B* and *B* tested by *C*. If we add one more slash on the end to form *A* `/` *B* `/` *C* `/`, then `anova` will also report *C* tested by the residual error.

▷ Example 11

We have collected data from a manufacturer that is evaluating which of five different brands of machinery to buy to perform a particular function in an assembly line. Twenty assembly-line employees were selected at random for training on these machines, with four employees assigned to learn a particular machine. The output from each employee (operator) on the brand of machine for which he trained was measured during four trial periods. In this example, the operator is nested within machine. Because of sickness and employee resignations, the final data are not balanced. The following table gives the mean output and sample size for each machine and operator combination.

```
. use http://www.stata-press.com/data/r12/machine, clear
(machine data)
```

```
. table machine operator, c(mean output n output) col f(%8.2f)
```

five brands of machine	operator nested in machine 1	2	3	4	Total
1	9.15	9.48	8.27	8.20	8.75
	2	4	3	4	13
2	15.03	11.55	11.45	11.52	12.47
	3	2	2	4	11
3	11.27	10.13	11.13		10.84
	3	3	3		9
4	16.10	18.97	15.35	16.60	16.65
	3	3	4	3	13
5	15.30	14.35	10.43		13.63
	4	4	3		11

Assuming that `operator` is random (that is, we wish to infer to the larger population of possible operators) and `machine` is fixed (that is, only these five machines are of interest), the typical test for `machine` uses `operator` nested within `machine` as the error term. `operator` nested within `machine` can be tested by residual error. Our earlier warning concerning designs with either unplanned missing cells or unbalanced cell sizes, or both, also applies to interpreting the ANOVA results from this unbalanced nested example.

```
. anova output machine / operator|machine /
                          Number of obs =      57     R-squared     =  0.8661
                          Root MSE      = 1.47089     Adj R-squared =  0.8077
```

Source	Partial SS	df	MS	F	Prob > F
Model	545.822288	17	32.1071934	14.84	0.0000
machine	430.980792	4	107.745198	13.82	0.0001
operator|machine	101.353804	13	7.79644648		
operator|machine	101.353804	13	7.79644648	3.60	0.0009
Residual	84.3766582	39	2.16350406		
Total	630.198947	56	11.2535526		

`operator|machine` is preceded by a slash, indicating that it is the error term for the terms before it (here `machine`). `operator|machine` is also followed by a slash that indicates it should be tested with residual error. The output lists the `operator|machine` term twice, once as the error term for machine, and again as a term tested by residual error. A line is placed in the ANOVA table to separate the two. In general, a dividing line is placed in the output to separate the terms into groups that are tested with the same error term. The overall model is tested by residual error and is separated from the rest of the table by a blank line at the top of the table.

The results indicate that the machines are not all equal and that there are significant differences between operators.

◁

▷ Example 12

Your company builds and operates sewage treatment facilities. You want to compare two particulate solutions during the particulate reduction step of the sewage treatment process. For each solution, two area managers are randomly selected to implement and oversee the change to the new treatment process in two of their randomly chosen facilities. Two workers at each of these facilities are trained to operate the new process. A measure of particulate reduction is recorded at various times during the month at each facility for each worker. The data are described below.

```
. use http://www.stata-press.com/data/r12/sewage
(Sewage treatment)
. describe

-------------------------------------------------------------------------------
Sorted by:  solution  manager  facility  worker
```

You want to determine if the two particulate solutions provide significantly different particulate reduction. You would also like to know if `manager`, `facility`, and `worker` are significant effects. `solution` is a fixed factor, whereas `manager`, `facility`, and `worker` are random factors.

In the following `anova` command, we use abbreviations for the variable names, which can sometimes make long ANOVA model statements easier to read.

```
. anova particulate s / m|s / f|m|s / w|f|m|s /, dropemptycells
                          Number of obs =      64     R-squared     =  0.6338
                          Root MSE      = 12.7445     Adj R-squared =  0.5194
```

Source	Partial SS	df	MS	F	Prob > F
Model	13493.6094	15	899.573958	5.54	0.0000
solution	7203.76563	1	7203.76563	17.19	0.0536
manager|solution	838.28125	2	419.140625		
manager|solution	838.28125	2	419.140625	0.55	0.6166
facility|manager|solution	3064.9375	4	766.234375		
facility|manager|solution	3064.9375	4	766.234375	2.57	0.1193
worker|facility|manager|solution	2386.625	8	298.328125		
worker|facility|manager|solution	2386.625	8	298.328125	1.84	0.0931
Residual	7796.25	48	162.421875		
Total	21289.8594	63	337.934276		

While solution is not declared significant at the 5% significance level, it is near enough to that threshold to warrant further investigation (see example 3 in [R] **anova postestimation** for a continuation of the analysis of these data).

◁

❑ Technical note

Why did we use the dropemptycells option with the previous anova? By default, Stata retains empty cells when building the design matrix and currently treats | and # the same in how it determines the possible number of cells. Retaining empty cells in an ANOVA with nested terms can cause your design matrix to become too large. In example 12, there are $1024 = 2 \times 4 \times 8 \times 16$ cells that are considered possible for the worker|facility|manager|solution term because the worker, facility, and manager variables are uniquely numbered. With the dropemptycells option, the worker|facility|manager|solution term requires just 16 columns in the design matrix (corresponding to the 16 unique workers).

Why did we not use the dropemptycells option in example 11, where operator is nested in machine? If you look at the table presented at the beginning of that example, you will see that operator is compactly instead of uniquely numbered (you need both operator number and machine number to determine the operator). Here the dropemptycells option would have only reduced our design matrix from 26 columns down to 24 columns (because there were only 3 operators instead of 4 for machines 3 and 5).

We suggest that you specify dropemptycells when there are nested terms in your ANOVA. You could also use the set emptycells drop command to accomplish the same thing; see [R] **set**.

❑

Mixed designs

An ANOVA can consist of both nested and crossed terms. A split-plot ANOVA design provides an example.

▷ Example 13

Two reading programs and three skill-enhancement techniques are under investigation. Ten classes of first-grade students were randomly assigned so that five classes were taught with one reading program and another five classes were taught with the other. The 30 students in each class were divided into six groups with 5 students each. Within each class, the six groups were divided randomly so that each of the three skill-enhancement techniques was taught to two of the groups within each class. At the end of the school year, a reading assessment test was administered to all the students. In this split-plot ANOVA, the whole-plot treatment is the two reading programs, and the split-plot treatment is the three skill-enhancement techniques.

In this split-plot ANOVA, the error term for `program` is `class` nested within `program`. The error term for `skill` and the `program` by `skill` interaction is the `class` by `skill` interaction nested within `program`. Other terms are also involved in the model and can be seen below.

Our `anova` command is too long to fit on one line of this manual. Where we have chosen to break the command into multiple lines is arbitrary. If we were typing this command into Stata, we would just type along and let Stata automatically wrap across lines, as necessary.

```

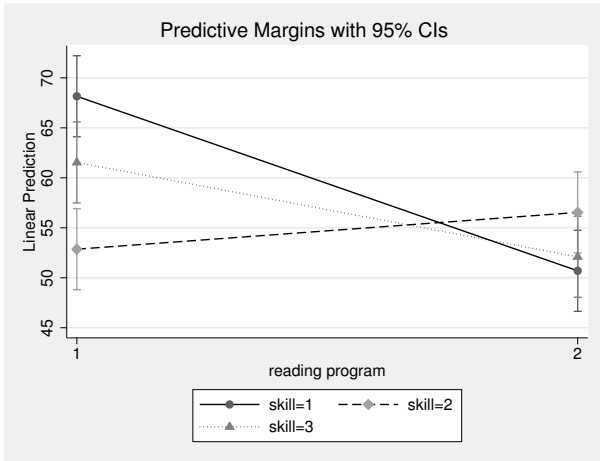
2 1	50.7	2.068542	24.51	0.000	46.64573	54.75427
2 2	56.54	2.068542	27.33	0.000	52.48573	60.59427
2 3	52.1	2.068542	25.19	0.000	48.04573	56.15427

```
. marginsplot, plot2opts(lp(dash) m(D)) plot3opts(lp(dot) m(T))
  Variables that uniquely identify margins: program skill
```



```
. margins, within(program)
Predictive margins                                Number of obs   =        300
Expression   : Linear prediction, predict()
within       : program
Empty cells  : reweight
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
program						
1	60.85333	1.194273	50.95	0.000	58.5126	63.19407
2	53.11333	1.194273	44.47	0.000	50.7726	55.45407

Because our ANOVA involves nested terms, we used the `within()` option of `margins`; see [R] **margins**.

skill 2 produces a low score when combined with program 1 and a high score when combined with program 2, demonstrating the interaction between the reading program and the skill-enhancement technique. You might conclude that the first reading program and the first skill-enhancement technique perform best when combined. However, notice the overlapping confidence interval for the first reading program and the third skill-enhancement technique.

◁

❑ Technical note

There are several valid ways to write complicated anova terms. In the reading experiment example (example 13), we had a term group|class#skill|program. This term can be read as group nested within both class and skill and further nested within program. You can also write this term as group|class#skill#program or group|program#class#skill or group|skill#class|program, etc. All variations will produce the same result. Some people prefer having only one '|' in a term and would use group|class#skill#program, which is read as group nested within class, skill, and program.

❑

Gertrude Mary Cox (1900–1978) was born on a farm near Dayton, Iowa. Initially intending to become superintendent of an orphanage, she enrolled at Iowa State College. There she majored in mathematics and attained the college's first Master's degree in statistics. After working on her PhD in psychological statistics for two years at the University of California–Berkeley, she decided to go back to Iowa State to work with George W. Snedecor. There she pursued her interest in and taught a course in design of experiments. That work led to her collaboration with W. G. Cochran, which produced a classic text. In 1940, when Snedecor shared with her his list of men he was nominating to head the statistics department at North Carolina State College, she wanted to know why she had not been included. He added her name, she won the position, and she built an outstanding department at North Carolina State. Cox retired early so she could work at the Research Triangle Institute in North Carolina. She consulted widely, served as editor of *Biometrics*, and was elected to the National Academy of Sciences.

Latin-square designs

You can use anova to analyze a Latin-square design. Consider the following example, published in Snedecor and Cochran (1989).

▷ Example 14

Data from a Latin-square design are as follows:

Row	Column 1	Column 2	Column 3	Column 4	Column 5
1	257(B)	230(E)	279(A)	287(C)	202(D)
2	245(D)	283(A)	245(E)	280(B)	260(C)
3	182(E)	252(B)	280(C)	246(D)	250(A)
4	203(A)	204(C)	227(D)	193(E)	259(B)
5	231(C)	271(D)	266(B)	334(A)	338(E)

In Stata, the data might appear as follows:

```
. use http://www.stata-press.com/data/r12/latinsq
. list
```

	row	c1	c2	c3	c4	c5
1.	1	257	230	279	287	202
2.	2	245	283	245	280	260
3.	3	182	252	280	246	250
4.	4	203	204	227	193	259
5.	5	231	271	266	334	338

Before `anova` can be used on these data, the data must be organized so that the outcome measurement is in one column. `reshape` is inadequate for this task because there is information about the treatments in the sequence of these observations. `pkshape` is designed to reshape this type of data; see [R] **pkshape**.

```
. pkshape row row c1-c5, order(beacd daebc ebcda acdeb cdbae)
. list
```

```

These methods will work with any type of Latin-square design, including those with replicated measurements. For more information, see [R] **pk**, [R] **pkcross**, and [R] **pkshape**.

Repeated-measures ANOVA

One approach for analyzing repeated-measures data is to use multivariate ANOVA (MANOVA); see [MV] **manova**. In this approach, the data are placed in wide form (see [D] **reshape**), and the repeated measures enter the MANOVA as dependent variables.

A second approach for analyzing repeated measures is to use `anova`. However, one of the underlying assumptions for the F tests in ANOVA is independence of observations. In a repeated-measures design, this assumption is almost certainly violated or is at least suspect. In a repeated-measures ANOVA, the subjects (or whatever the experimental units are called) are observed for each level of one or more of the other categorical variables in the model. These variables are called the repeated-measure variables. Observations from the same subject are likely to be correlated.

The approach used in repeated-measures ANOVA to correct for this lack of independence is to apply a correction to the degrees of freedom of the F test for terms in the model that involve repeated measures. This correction factor, ϵ, lies between the reciprocal of the degrees of freedom for the repeated term and 1. Box (1954) provided the pioneering work in this area. Milliken and Johnson (2009) refer to the lower bound of this correction factor as Box's conservative correction factor. Winer, Brown, and Michels (1991) call it simply the conservative correction factor.

Geisser and Greenhouse (1958) provide an estimate for the correction factor called the Greenhouse–Geisser ϵ. This value is estimated from the data. Huynh and Feldt (1976) show that the Greenhouse–Geisser ϵ tends to be conservatively biased. They provide a revised correction factor called the Huynh–Feldt ϵ. When the Huynh–Feldt ϵ exceeds 1, it is set to 1. Thus there is a natural ordering for these correction factors:

$$\text{Box's conservative } \epsilon \leq \text{Greenhouse–Geisser } \epsilon \leq \text{Huynh–Feldt } \epsilon \leq 1$$

A correction factor of 1 is the same as no correction.

`anova` with the `repeated()` option computes these correction factors and displays the revised test results in a table that follows the standard ANOVA table. In the resulting table, H-F stands for Huynh–Feldt, G-G stands for Greenhouse–Geisser, and Box stands for Box's conservative ϵ.

▷ Example 15

This example is taken from table 4.3 of Winer, Brown, and Michels (1991). The reaction time for five subjects each tested with four drugs was recorded in the variable `score`. Here is a table of the data (see [P] **tabdisp** if you are unfamiliar with `tabdisp`):

```
. use http://www.stata-press.com/data/r12/t43, clear
(T4.3 -- Winer, Brown, Michels)
. tabdisp person drug, cellvar(score)
```

person	drug 1	2	3	4
1	30	28	16	34
2	14	18	10	22
3	24	20	18	30
4	38	34	20	44
5	26	28	14	30

`drug` is the repeated variable in this simple repeated-measures ANOVA example. The ANOVA is specified as follows:

```
. anova score person drug, repeated(drug)
                          Number of obs =      20     R-squared     =  0.9244
                          Root MSE      = 3.06594     Adj R-squared =  0.8803

                     drug |       3     24.76     0.0000    0.0000   0.0006    0.0076
                 Residual |      12
--------------------------+----------------------------------------------------
```

Here the Huynh–Feldt ϵ is 1.0789, which is larger than 1. It is reset to 1, which is the same as making no adjustment to the standard test computed in the main ANOVA table. The Greenhouse–Geisser ϵ is 0.6049, and its associated p-value is computed from an F ratio of 24.76 using 1.8147 ($= 3\epsilon$) and 7.2588 ($= 12\epsilon$) degrees of freedom. Box's conservative ϵ is set equal to the reciprocal of the degrees of freedom for the repeated term. Here it is 1/3, so Box's conservative test is computed using 1 and 4 degrees of freedom for the observed F ratio of 24.76.

Even for Box's conservative ϵ, `drug` is significant with a p-value of 0.0076. The following table gives the predictive marginal mean `score` (that is, response time) for each of the four drugs:

```
. margins drug
Predictive margins                                Number of obs   =         20
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
drug						
1	26.4	1.371131	19.25	0.000	23.71263	29.08737
2	25.6	1.371131	18.67	0.000	22.91263	28.28737
3	15.6	1.371131	11.38	0.000	12.91263	18.28737
4	32	1.371131	23.34	0.000	29.31263	34.68737

The ANOVA table for this example provides an F test for `person`, but you should ignore it. An appropriate test for `person` would require replication (that is, multiple measurements for `person` and `drug` combinations). Also, without replication there is no test available for investigating the interaction between `person` and `drug`.

◁

▷ Example 16

Table 7.7 of Winer, Brown, and Michels (1991) provides another repeated-measures ANOVA example. There are four dial shapes and two methods for calibrating dials. Subjects are nested within calibration method, and an accuracy score is obtained. The data are shown below.

```
. use http://www.stata-press.com/data/r12/t77
(T7.7 -- Winer, Brown, Michels)
. tabdisp shape subject calib, cell(score)
```

4 dial shapes	2 methods for calibrating dials and subject nested in calib: 1			2		
	1	2	3	1	2	3
1	0	3	4	4	5	7
2	0	1	3	2	4	5
3	5	5	6	7	6	8
4	3	4	2	8	6	9

The calibration method and dial shapes are fixed factors, whereas subjects are random. The appropriate test for calibration method uses the nested subject term as the error term. Both the dial shape and the interaction between dial shape and calibration method are tested with the dial shape by subject interaction nested within calibration method. Here we drop this term from the `anova` command, and it becomes residual error. The dial shape is the repeated variable because each subject is tested with all four dial shapes. Here is the `anova` command that produces the desired results:

```
. anova score calib / subject|calib shape calib#shape, repeated(shape)
                          Number of obs =      24     R-squared     =  0.8925
                          Root MSE      = 1.11181     Adj R-squared =  0.7939

-------------------------+----------------------------------------------------
```

The repeated-measure ϵ corrections are applied to any terms that are tested in the main ANOVA table and have the repeated variable in the term. These ϵ corrections are given in a table below the main ANOVA table. Here the repeated-measures tests for `shape` and `calib#shape` are presented.

Calibration method is significant, as is dial shape. The interaction between calibration method and dial shape is not significant. The repeated-measure ϵ corrections do not change these conclusions, but they do change the significance level for the tests on `shape` and `calib#shape`. Here, though, unlike in the previous example, the Huynh–Feldt ϵ is less than 1.

Here are the predictive marginal mean scores for calibration method and dial shapes. Because the interaction was not significant, we request only the `calib` and `shape` predictive margins.

```
. margins, within(calib)

◁

❑ Technical note

The computation of the Greenhouse–Geisser and Huynh–Feldt epsilons in a repeated-measures ANOVA requires the number of levels and degrees of freedom for the between-subjects error term, as well as a value computed from a pooled covariance matrix. The observations are grouped based on all but the lowest-level variable in the between-subjects error term. The covariance over the repeated variables is computed for each resulting group, and then these covariance matrices are pooled. The dimension of the pooled covariance matrix is the number of levels of the repeated variable (or combination of levels for multiple repeated variables). In example 16, there are four levels of the repeated variable (`shape`), so the resulting covariance matrix is 4×4.

The `anova` command automatically attempts to determine the between-subjects error term and the lowest-level variable in the between-subjects error term to group the observations for computation of the pooled covariance matrix. `anova` issues an error message indicating that the `bse()` or `bseunit()` option is required when `anova` cannot determine them. You may override the default selections of `anova` by specifying the `bse()`, `bseunit()`, or `grouping()` option. The term specified in the `bse()` option must be a term in the ANOVA model.

The default selection for the between-subjects error term (the `bse()` option) is the interaction of the nonrepeated categorical variables in the ANOVA model. The first variable listed in the between-subjects error term is automatically selected as the lowest-level variable in the between-subjects error term but can be overridden with the `bseunit(`*varname*`)` option. *varname* is often a term, such as subject or subsample within subject, and is most often listed first in the term because of the nesting notation of ANOVA. This term makes sense in most repeated-measures ANOVA designs when the terms of the model are written in standard form. For instance, in example 16, there were three categorical variables (`subject`, `calib`, and `shape`), with `shape` being the repeated variable. Here `anova` looked for a term involving only `subject` and `calib` to determine the between-subjects error term. It found `subject|calib` as the term with six levels and 4 degrees of freedom. `anova` then picked `subject` as the default for the `bseunit()` option (the lowest variable in the between-subjects error term) because it was listed first in the term.

The grouping of observations proceeds, based on the different combinations of values of the variables in the between-subjects error term, excluding the lowest level variable (as found by default or as specified with the `bseunit()` option). You may specify the `grouping()` option to change the default grouping used in computing the pooled covariance matrix.

The between-subjects error term, number of levels, degrees of freedom, lowest variable in the term, and grouping information are presented after the main ANOVA table and before the rest of the repeated-measures output.

❑

▷ Example 17

Data with two repeated variables are given in table 7.13 of Winer, Brown, and Michels (1991). The accuracy scores of subjects making adjustments to three dials during three different periods are recorded. Three subjects are exposed to a certain noise background level, whereas a different set of three subjects is exposed to a different noise background level. Here is a table of accuracy scores for the `noise`, `subject`, `period`, and `dial` variables:

```
. use http://www.stata-press.com/data/r12/t713
(T7.13 -- Winer, Brown, Michels)
. tabdisp subject dial period, by(noise) cell(score) stubwidth(11)
```

noise background and subject nested in noise	10 minute time periods and dial								
	1			2			3		
	1	2	3	1	2	3	1	2	3
1									
1	45	53	60	40	52	57	28	37	46
2	35	41	50	30	37	47	25	32	41
3	60	65	75	58	54	70	40	47	50
2									
1	50	48	61	25	34	51	16	23	35
2	42	45	55	30	37	43	22	27	37
3	56	60	77	40	39	57	31	29	46

`noise`, `period`, and `dial` are fixed, whereas `subject` is random. Both `period` and `dial` are repeated variables. The ANOVA for this example is specified next.

```
. anova score noise / subject|noise period noise#period
> / period#subject|noise  dial noise#dial / dial#subject|noise
> period#dial noise#period#dial, repeated(period dial)
```

```
                          Number of obs =      54     R-squared     =  0.9872
                          Root MSE      = 2.81859     Adj R-squared =  0.9576
```

For each repeated variable and for each combination of interactions of repeated variables, there are different ϵ correction values. The `anova` command produces tables for each applicable combination.

The two most significant factors in this model appear to be `dial` and `period`. The `noise` by `period` interaction may also be significant, depending on the correction factor you use. Below is a table of predictive margins for the accuracy score for dial, period, and noise by period.

```
. margins, within(dial)
Predictive margins                              Number of obs   =         54
Expression   : Linear prediction, predict()

Expression   : Linear prediction, predict()
within       : noise period
Empty cells  : reweight
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
noise#period						
1 1	53.77778	.9395297	57.24	0.000	51.93633	55.61922
1 2	49.44444	.9395297	52.63	0.000	47.603	51.28589
1 3	38.44444	.9395297	40.92	0.000	36.603	40.28589
2 1	54.88889	.9395297	58.42	0.000	53.04744	56.73033
2 2	39.55556	.9395297	42.10	0.000	37.71411	41.397
2 3	29.55556	.9395297	31.46	0.000	27.71411	31.397

Dial shape 3 produces the highest score, and scores decrease over the periods.

◁

Example 17 had two repeated-measurement variables. Up to four repeated-measurement variables may be specified in the `anova` command.

Saved results

`anova` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(mss)`	model sum of squares
`e(df_m)`	model degrees of freedom
`e(rss)`	residual sum of squares
`e(df_r)`	residual degrees of freedom
`e(r2)`	R-squared
`e(r2_a)`	adjusted R-squared
`e(F)`	F statistic
`e(rmse)`	root mean squared error
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(ss_#)`	sum of squares for term #
`e(df_#)`	numerator degrees of freedom for term #
`e(ssdenom_#)`	denominator sum of squares for term # (when using nonresidual error)
`e(dfdenom_#)`	denominator degrees of freedom for term # (when using nonresidual error)
`e(F_#)`	F statistic for term # (if computed)
`e(N_bse)`	number of levels of the between-subjects error term
`e(df_bse)`	degrees of freedom for the between-subjects error term
`e(box#)`	Box's conservative epsilon for a particular combination of repeated variables (`repeated()` only)
`e(gg#)`	Greenhouse–Geisser epsilon for a particular combination of repeated variables (`repeated()` only)
`e(hf#)`	Huynh–Feldt epsilon for a particular combination of repeated variables (`repeated()` only)
`e(rank)`	rank of `e(V)`

Macros

e(cmd)	anova
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(varnames)	names of the right-hand-side variables
e(term_#)	term #
e(errorterm_#)	error term for term # (when using nonresidual error)
e(sstype)	type of sum of squares; sequential or partial
e(repvars)	names of repeated variables (repeated() only)
e(repvar#)	names of repeated variables for a particular combination (repeated() only)
e(model)	ols
e(wtype)	weight type
e(wexp)	weight expression
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators
e(Srep)	covariance matrix based on repeated measures (repeated() only)

Functions

e(sample)	marks estimation sample

Methods and formulas

anova is implemented as an ado-file.

Title

anova postestimation — Postestimation tools for anova

Description

The following postestimation commands are of special interest after `anova`:

Command	Description
`dfbeta`	DFBETA influence statistics
`estat hettest`	tests for heteroskedasticity
`estat imtest`	information matrix test
`estat ovtest`	Ramsey regression specification-error test for omitted variables
`estat szroeter`	Szroeter's rank test for heteroskedasticity
`estat vif`	variance inflation factors for the independent variables
`acprplot`	augmented component-plus-residual plot
`avplot`	added-variable plot
`avplots`	all added-variable plots in one image
`cprplot`	component-plus-residual plot
`lvr2plot`	leverage-versus-squared-residual plot
`rvfplot`	residual-versus-fitted plot
`rvpplot`	residual-versus-predictor plot

For information about these commands, see [R] **regress postestimation**.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation commands

In addition to the common estat commands (see [R] **estat**), estat hettest, estat imtest, estat ovtest, estat szroeter, and estat vif are also available. dfbeta is also available. The syntax for dfbeta and these estat commands is the same as after regress; see [R] **regress postestimation**.

In addition to the standard syntax of test (see [R] **test**), test after anova has three additionally allowed syntaxes; see below. test performs Wald tests of expressions involving the coefficients of the underlying regression model. Simple and composite linear hypotheses are possible.

Syntax for predict

predict after anova follows the same syntax as predict after regress and can provide predictions, residuals, standardized residuals, Studentized residuals, the standard error of the residuals, the standard error of the prediction, the diagonal elements of the projection (hat) matrix, and Cook's D. See [R] **regress postestimation** for details.

Syntax for test after anova

In addition to the standard syntax of test (see [R] **test**), test after anova also allows the following:

```
test, test(matname) [mtest[(opt)] matvlc(matname)]                    syntax a

test, showorder                                                       syntax b

test [term [term ...]] [/ term [term ...]] [, symbolic]               syntax c
```

syntax a test expression involving the coefficients of the underlying regression model; you provide information as a matrix

syntax b show underlying order of design matrix, which is useful when constructing *matname* argument of the test() option

syntax c test effects and show symbolic forms

Menu

Statistics > Linear models and related > ANOVA/MANOVA > Test linear hypotheses after anova

Options for test after anova

test(*matname*) is required with syntax a of test. The rows of *matname* specify linear combinations of the underlying design matrix of the ANOVA that are to be jointly tested. The columns correspond to the underlying design matrix (including the constant if it has not been suppressed). The column and row names of *matname* are ignored.

A listing of the constraints imposed by the test() option is presented before the table containing the tests. You should examine this table to verify that you have applied the linear combinations you desired. Typing test, showorder allows you to examine the ordering of the columns for the design matrix from the ANOVA.

`mtest`[`(`*opt*`)`] specifies that tests are performed for each condition separately. *opt* specifies the method for adjusting p-values for multiple testing. Valid values for *opt* are

`bonferroni`	Bonferroni's method
`holm`	Holm's method
`sidak`	Šidák's method
`noadjust`	no adjustment is to be made

Specifying `mtest` with no argument is equivalent to `mtest(noadjust)`.

`matvlc(`*matname*`)`, a programmer's option, saves the variance–covariance matrix of the linear combinations involved in the suite of tests. For the test $\mathbf{Lb} = \mathbf{c}$, what is returned in *matname* is $\mathbf{L}V\mathbf{L}'$, where V is the estimated variance–covariance matrix of $\mathbf{b}$.

`showorder` causes `test` to list the definition of each column in the design matrix. `showorder` is not allowed with any other option.

`symbolic` requests the symbolic form of the test rather than the test statistic. When this option is specified with no terms (`test, symbolic`), the symbolic form of the estimable functions is displayed.

Remarks

Remarks are presented under the following headings:

Testing effects
Obtaining symbolic forms
Testing coefficients and contrasts of margins

See examples 4, 7, 8, 13, 15, 16, and 17 in [R] **anova** for examples that use the `margins` command.

Testing effects

After fitting a model using `anova`, you can test for the significance of effects in the ANOVA table, as well as for effects that are not reported in the ANOVA table, by using the `test` or `contrast` command. You follow `test` or `contrast` by the list of effects that you wish to test. By default, these commands use the residual mean squared error in the denominator of the F ratio. You can specify other error terms by using the slash notation, just as you would with `anova`. See [R] **contrast** for details on this command.

▷ Example 1

Recall our byssinosis example (example 8) in [R] **anova**:

```
. anova prob workplace smokes race workplace#smokes workplace#race
> smokes#race workplace#smokes#race [aweight=pop]
(sum of wgt is   5.4190e+03)
                          Number of obs =      65     R-squared     =  0.8300
                          Root MSE      = .025902     Adj R-squared =  0.7948
```

Source	Partial SS	df	MS	F	Prob > F
Model	.173646538	11	.015786049	23.53	0.0000
workplace	.097625175	2	.048812588	72.76	0.0000
smokes	.013030812	1	.013030812	19.42	0.0001
race	.001094723	1	.001094723	1.63	0.2070
workplace#smokes	.019690342	2	.009845171	14.67	0.0000
workplace#race	.001352516	2	.000676258	1.01	0.3718
smokes#race	.001662874	1	.001662874	2.48	0.1214
workplace#smokes#race	.000950841	2	.00047542	0.71	0.4969
Residual	.035557766	53	.000670901		
Total	.209204304	64	.003268817		

We can easily obtain a test on a particular term from the ANOVA table. Here are two examples:

```
. test smokes
```

Source	Partial SS	df	MS	F	Prob > F
smokes	.013030812	1	.013030812	19.42	0.0001
Residual	.035557766	53	.000670901		

```
. test smokes#race
```

Source	Partial SS	df	MS	F	Prob > F
smokes#race	.001662874	1	.001662874	2.48	0.1214
Residual	.035557766	53	.000670901		

Both of these tests use residual error by default and agree with the ANOVA table produced earlier.

We could have performed these same tests with `contrast`:

```
. contrast smokes
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
smokes	1	19.42	0.0001
Residual	53		

```
. contrast smokes#race
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
smokes#race	1	2.48	0.1214
Residual	53		

❑ Technical note

After `anova`, you can use the '`/`' syntax in `test` or `contrast` to perform tests with a variety of non-$\sigma^2\mathbf{I}$ error structures. However, in most unbalanced models, the mean squares are not independent and do not have equal expectations under the null hypothesis. Also, be warned that you assume responsibility for the validity of the test statistic.

❑

▷ Example 2

We return to the nested ANOVA example (example 11) in [R] **anova**, where five brands of machinery were compared in an assembly line. We can obtain appropriate tests for the nested terms using `test`, even if we had run the `anova` command without initially indicating the proper error terms.

```
. use http://www.stata-press.com/data/r12/machine
(machine data)
. anova output machine operator|machine
                          Number of obs =      57     R-squared     =  0.8661
                          Root MSE      = 1.47089     Adj R-squared =  0.8077
                  Source |  Partial SS    df       MS           F     Prob > F
-------------------------+----------------------------------------------------
                   Model |  545.822288    17  32.1071934       14.84     0.0000
                         |
                 machine |  430.980792     4  107.745198       49.80     0.0000
         operator|machine |  101.353804    13  7.79644648        3.60     0.0009
                         |
                Residual |  84.3766582    39  2.16350406
-------------------------+----------------------------------------------------
                   Total |  630.198947    56  11.2535526
```

In this ANOVA table, `machine` is tested with residual error. With this particular nested design, the appropriate error term for testing `machine` is `operator` nested within `machine`, which is easily obtained from `test`.

```
. test machine / operator|machine
                  Source |  Partial SS    df       MS           F     Prob > F
-------------------------+----------------------------------------------------
                 machine |  430.980792     4  107.745198       13.82     0.0001
         operator|machine |  101.353804    13  7.79644648
```

This result from `test` matches what we obtained from our `anova` command.

◁

▷ Example 3

The other nested ANOVA example (example 12) in [R] **anova** was based on the sewage data. The ANOVA table is presented here again. As before, we will use abbreviations of variable names in typing the commands.

```
. use http://www.stata-press.com/data/r12/sewage
(Sewage treatment)
```

```
. anova particulate s / m|s / f|m|s / w|f|m|s /, dropemptycells
                          Number of obs =      64     R-squared     =  0.6338
                          Root MSE      = 12.7445     Adj R-squared =  0.5194
```

Source	Partial SS	df	MS	F	Prob > F
Model	13493.6094	15	899.573958	5.54	0.0000
solution	7203.76563	1	7203.76563	17.19	0.0536
manager|solution	838.28125	2	419.140625		
manager|solution	838.28125	2	419.140625	0.55	0.6166
facility|manager|solution	3064.9375	4	766.234375		
facility|manager|solution	3064.9375	4	766.234375	2.57	0.1193
worker|facility|manager|solution	2386.625	8	298.328125		
worker|facility|manager|solution	2386.625	8	298.328125	1.84	0.0931
Residual	7796.25	48	162.421875		
Total	21289.8594	63	337.934276		

In practice, it is often beneficial to pool nonsignificant nested terms to increase the power of tests on remaining terms. One rule of thumb is to allow the pooling of a term whose p-value is larger than 0.25. In this sewage example, the p-value for the test of `manager` is 0.6166. This value indicates that the manager effect is negligible and might be ignored. Currently, `solution` is tested by `manager|solution`, which has only 2 degrees of freedom. If we pool the `manager` and `facility` terms and use this pooled estimate as the error term for `solution`, we would have a term with 6 degrees of freedom.

Below are two tests: a test of `solution` with the pooled `manager` and `facility` terms and a test of this pooled term by `worker`.

```
. test s / m|s f|m|s
```

Source	Partial SS	df	MS	F	Prob > F
solution	7203.76563	1	7203.76563	11.07	0.0159
manager|solution facility|manager|solution	3903.21875	6	650.536458		

```
. test m|s f|m|s / w|f|m|s
```

Source	Partial SS	df	MS	F	Prob > F
manager|solution facility|manager|solution	3903.21875	6	650.536458	2.18	0.1520
worker|facility|manager|solution	2386.625	8	298.328125		

In the first test, we included two terms after the forward slash (`m|s` and `f|m|s`). `test` after `anova` allows multiple terms both before and after the slash. The terms before the slash are combined and are then tested by the combined terms that follow the slash (or residual error if no slash is present).

The p-value for `solution` using the pooled term is 0.0159. Originally, it was 0.0536. The increase in the power of the test is due to the increase in degrees of freedom for the pooled error term.

We can get identical results if we drop `manager` from the `anova` model. (This dataset has unique numbers for each facility so that there is no confusion of facilities when `manager` is dropped.)

```
. anova particulate s / f|s / w|f|s /, dropemptycells
                          Number of obs =      64     R-squared     =  0.6338
                          Root MSE      = 12.7445     Adj R-squared =  0.5194
```

Source	Partial SS	df	MS	F	Prob > F
Model	13493.6094	15	899.573958	5.54	0.0000
solution	7203.76563	1	7203.76563	11.07	0.0159
facility|solution	3903.21875	6	650.536458		
facility|solution	3903.21875	6	650.536458	2.18	0.1520
worker|facility|solution	2386.625	8	298.328125		
worker|facility|solution	2386.625	8	298.328125	1.84	0.0931
Residual	7796.25	48	162.421875		
Total	21289.8594	63	337.934276		

This output agrees with our earlier `test` results. ◁

In the following example, two terms from the `anova` are jointly tested (pooled).

▷ Example 4

In example 10 of [R] **anova**, we fit the model `anova drate region c.mage region#c.mage`. Now we use the `contrast` command to test for the overall significance of `region`.

```
. contrast region region#c.mage, overall
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
region	3	7.40	0.0004
region#c.mage	3	0.86	0.4689
Overall	6	5.65	0.0002
Residual	42		

The overall F statistic associated with the `region` and `region#c.mage` terms is 5.65, and it is significant at the 0.02% level.

In the ANOVA output, the `region` term, by itself, had a sum of squares of 1166.15, which, based on 3 degrees of freedom, yielded an F statistic of 7.40 and a significance level of 0.0004. This is the same test that is reported by `contrast` in the row labeled `region`. Likewise, the test from the ANOVA output for the `region#c.mage` term is reproduced in the second row of the `contrast` output. ◁

Obtaining symbolic forms

`test` can produce the symbolic form of the estimable functions and symbolic forms for particular tests.

▷ Example 5

After fitting an ANOVA model, we type `test, symbolic` to obtain the symbolic form of the estimable functions. For instance, returning to our blood pressure data introduced in example 4 of [R] **anova**, let's begin by reestimating `systolic` on `drug`, `disease`, and `drug#disease`:

```
. use http://www.stata-press.com/data/r12/systolic, clear
(Systolic Blood Pressure Data)
. anova systolic drug##disease
                          Number of obs =      58     R-squared     =  0.4560
                          Root MSE      = 10.5096     Adj R-squared =  0.3259
                 Source | Partial SS    df       MS           F     Prob > F
------------------------+----------------------------------------------------
                  Model |  4259.33851    11  387.212591       3.51     0.0013
                        |
                   drug |  2997.47186     3  999.157287       9.05     0.0001
                disease |  415.873046     2  207.936523       1.88     0.1637
           drug#disease |  707.266259     6   117.87771       1.07     0.3958
                        |
                Residual |  5080.81667    46  110.452536

To obtain the symbolic form of the estimable functions, type

```
. test, symbolic
drug
           1  -(r2+r3+r4-r0)
           2   r2
           3   r3
           4   r4
disease
           1  -(r6+r7-r0)
           2   r6
           3   r7
drug#disease
        1  1  -(r2+r3+r4+r6+r7-r12-r13-r15-r16-r18-r19-r0)
        1  2   r6 - (r12+r15+r18)
        1  3   r7 - (r13+r16+r19)
        2  1   r2 - (r12+r13)
        2  2   r12
        2  3   r13
        3  1   r3 - (r15+r16)
        3  2   r15
        3  3   r16
        4  1   r4 - (r18+r19)
        4  2   r18
        4  3   r19
_cons           r0
```

◁

▷ Example 6

To obtain the symbolic form for a particular test, we type `test` *term* [*term* ...], `symbolic`. For instance, the symbolic form for the test of the main effect of `drug` is

```
. test drug, symbolic
drug
           1  -(r2+r3+r4)
           2   r2
           3   r3
           4   r4
disease
           1  0
           2  0
           3  0
drug#disease
        1  1  -1/3 (r2+r3+r4)
        1  2  -1/3 (r2+r3+r4)
        1  3  -1/3 (r2+r3+r4)
        2  1   1/3 r2
        2  2   1/3 r2
        2  3   1/3 r2
        3  1   1/3 r3
        3  2   1/3 r3
        3  3   1/3 r3
        4  1   1/3 r4
        4  2   1/3 r4
        4  3   1/3 r4
_cons          0
```

If we omit the `symbolic` option, we instead see the result of the test:

```
. test drug
```

Source	Partial SS	df	MS	F	Prob > F
drug	2997.47186	3	999.157287	9.05	0.0001
Residual	5080.81667	46	110.452536		

◁

Testing coefficients and contrasts of margins

The `test` command allows you to perform tests directly on the coefficients of the underlying regression model. For instance, the coefficient on the third `drug` and the second `disease` is referred to as `3.drug#2.disease`. This could also be written as `i3.drug#i2.disease`, or `_b[3.drug#2.disease]`, or even `_coef[i3.drug#i2.disease]`; see [U] **13.5 Accessing coefficients and standard errors**.

▷ Example 7

Let's begin by testing whether the coefficient on the third `drug` is equal to the coefficient on the fourth in our blood pressure data. We have already fit the model `anova systolic drug##disease` (equivalent to `anova systolic drug disease drug#disease`), and you can see the results of that estimation in example 5. Even though we have performed many tasks since we fit the model, Stata still remembers, and we can perform tests at any time.

```
. test 3.drug = 4.drug
 ( 1)  3.drug - 4.drug = 0
       F(  1,    46) =    0.13
            Prob > F =    0.7234
```

We find that the two coefficients are not significantly different, at least at any significance level smaller than 73%.

For more complex tests, the `contrast` command often provides a more concise way to specify the test we are interested in and prevents us from having to write the tests in terms of the regression coefficients. With `contrast`, we instead specify our tests in terms of differences in the marginal means for the levels of a particular factor. For example, if we want to compare the third and fourth drugs, we can test the difference in the mean impact on systolic blood pressure separately for each disease using the `@` operator. We also use the reverse adjacent operator, `ar.`, to compare the fourth level of drug with the previous level.

```
. contrast ar4.drug@disease
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
drug@disease			
(4 vs 3) 1	1	0.13	0.7234
(4 vs 3) 2	1	1.76	0.1917
(4 vs 3) 3	1	0.65	0.4230
Joint	3	0.85	0.4761
Residual	46		

	Contrast	Std. Err.	[95% Conf.	Interval]
drug@disease				
(4 vs 3) 1	-2.733333	7.675156	-18.18262	12.71595
(4 vs 3) 2	8.433333	6.363903	-4.376539	21.24321
(4 vs 3) 3	5.7	7.050081	-8.491077	19.89108

None of the individual contrasts shows significant differences between the third drug and the fourth drug. Likewise, the overall F statistic is 0.85, which is hardly significant. We cannot reject the hypothesis that the third drug has the same effect as the fourth drug.

◁

❑ Technical note

Alternatively, we could have specified these tests based on the coefficients of the underlying regression model using the `test` command. We would have needed to perform tests on the coefficients for `drug` and for the coefficients on `drug` interacted with `disease` in order to test for differences in the means mentioned above. To do this, we start with our previous `test` command:

```
. test 3.drug = 4.drug
```

Notice that the F statistic for this test is equivalent to the test labeled `(4 vs 3) 1` in the `contrast` output. Let's now add the constraint that the coefficient on the third drug interacted with the third disease is equal to the coefficient on the fourth drug, again interacted with the third disease. We do that by typing the new constraint and adding the `accumulate` option:

```
. test 3.drug#3.disease = 4.drug#3.disease, accumulate
 ( 1)  3.drug - 4.drug = 0
 ( 2)  3.drug#3.disease - 4.drug#3.disease = 0
       F(  2,    46) =    0.39
            Prob > F =    0.6791
```

So far, our test includes the equality of the two drug coefficients, along with the equality of the two drug coefficients when interacted with the third disease. Now we add two more equations, one for each of the remaining two diseases:

```
. test 3.drug#2.disease = 4.drug#2.disease, accumulate
 ( 1)  3.drug - 4.drug = 0
 ( 2)  3.drug#3.disease - 4.drug#3.disease = 0
 ( 3)  3.drug#2.disease - 4.drug#2.disease = 0
       F(  3,    46) =    0.85
            Prob > F =    0.4761
. test 3.drug#1.disease = 4.drug#1.disease, accumulate
 ( 1)  3.drug - 4.drug = 0
 ( 2)  3.drug#3.disease - 4.drug#3.disease = 0
 ( 3)  3.drug#2.disease - 4.drug#2.disease = 0
 ( 4)  3o.drug#1b.disease - 4o.drug#1b.disease = 0
       Constraint 4 dropped
       F(  3,    46) =    0.85
            Prob > F =    0.4761
```

The overall F statistic reproduces the one from the joint test in the `contrast` output.

You may notice that we also got the message "Constraint 4 dropped". For the technically inclined, this constraint was unnecessary, given the normalization of the model. If we specify all the constraints involved in our test or use `contrast`, we need not worry about the normalization because Stata handles this automatically.

❑

The `test()` option of `test` provides another alternative for testing coefficients. Instead of spelling out each coefficient involved in the test, a matrix representing the test provides the needed information. `test, showorder` shows the order of the terms in the ANOVA corresponding to the order of the columns for the matrix argument of `test()`.

▷ Example 8

We repeat the last test of example 7 above with the `test()` option. First, we view the definition and order of the columns underlying the ANOVA performed on the systolic data.

```
. test, showorder
 Order of columns in the design matrix
      1: (drug==1)
      2: (drug==2)
      3: (drug==3)
      4: (drug==4)
      5: (disease==1)
      6: (disease==2)
      7: (disease==3)
      8: (drug==1)*(disease==1)
      9: (drug==1)*(disease==2)
     10: (drug==1)*(disease==3)
     11: (drug==2)*(disease==1)
     12: (drug==2)*(disease==2)
     13: (drug==2)*(disease==3)
     14: (drug==3)*(disease==1)
     15: (drug==3)*(disease==2)
     16: (drug==3)*(disease==3)
     17: (drug==4)*(disease==1)
     18: (drug==4)*(disease==2)
     19: (drug==4)*(disease==3)
     20: _cons
```

Columns 1–4 correspond to the four levels of `drug`. Columns 5–7 correspond to the three levels of `disease`. Columns 8–19 correspond to the interaction of `drug` and `disease`. The last column corresponds to `_cons`, the constant in the model.

We construct the matrix `dr3vs4` with the same four constraints as the last test shown in example 7 and then use the `test(dr3vs4)` option to perform the test.

```
. mat dr3vs4 = (0,0,1,-1,  0,0,0,  0,0,0,0,0,0,0,0,0, 0, 0, 0,  0 \
>               0,0,0, 0,  0,0,0,  0,0,0,0,0,0,0,0,1, 0, 0,-1,  0 \
>               0,0,0, 0,  0,0,0,  0,0,0,0,0,0,0,1,0, 0,-1, 0,  0 \
>               0,0,0, 0,  0,0,0,  0,0,0,0,0,0,1,0,0,-1, 0, 0,  0)
. test, test(dr3vs4)
 ( 1)  3.drug - 4.drug = 0
 ( 2)  3.drug#3.disease - 4.drug#3.disease = 0
 ( 3)  3.drug#2.disease - 4.drug#2.disease = 0
 ( 4)  3o.drug#1b.disease - 4o.drug#1b.disease = 0
       Constraint 4 dropped
       F(  3,    46) =    0.85
            Prob > F =    0.4761
```

Here the effort involved with spelling out the coefficients is similar to that of constructing a matrix and using it in the `test()` option. When the test involving coefficients is more complicated, the `test()` option may be more convenient than specifying the coefficients directly in `test`. However, as previously demonstrated, `contrast` may provide an even simpler method for testing the same hypothesis.

◁

After fitting an ANOVA model, various contrasts (1-degree-of-freedom tests comparing different levels of a categorical variable) are often of interest. `contrast` can perform each 1-degree-of-freedom test in addition to the combined test, even in cases in which the contrasts do not correspond to one of the contrast operators.

▷ Example 9

Rencher and Schaalje (2008) illustrate 1-degree-of-freedom contrasts for an ANOVA comparing the net weight of cans filled by five machines (labeled `A`–`E`). The data were originally obtained from Ostle and Mensing (1975). Rencher and Schaalje use a cell-means ANOVA model approach for this problem. We could do the same by using the `noconstant` option of `anova`; see [R] **anova**. Instead, we obtain the same results by using the standard overparameterized ANOVA approach (that is, we keep the constant in the model).

```
. use http://www.stata-press.com/data/r12/canfill
(Can Fill Data)
. list, sepby(machine)
```

	machine	weight
1.	A	11.95
2.	A	12.00
3.	A	12.25
4.	A	12.10
5.	B	12.18
6.	B	12.11
7.	C	12.16
8.	C	12.15
9.	C	12.08
10.	D	12.25
11.	D	12.30
12.	D	12.10
13.	E	12.10
14.	E	12.04
15.	E	12.02
16.	E	12.02

```
. anova weight machine
```

```
                   Number of obs =      16     R-squared     =  0.4123
                   Root MSE      = .087758     Adj R-squared =  0.1986
```

Source	Partial SS	df	MS	F	Prob > F
Model	.059426993	4	.014856748	1.93	0.1757
machine	.059426993	4	.014856748	1.93	0.1757
Residual	.084716701	11	.007701518		
Total	.144143694	15	.00960958		

The four 1-degree-of-freedom tests of interest among the five machines are `A` and `D` versus `B`, `C`, and `E`; `B` and `E` versus `C`; `A` versus `D`; and `B` versus `E`. We can specify these tests as user-defined contrasts by placing the corresponding contrast coefficients into positions related to the five levels of machine as described in *User-defined contrasts* of [R] **contrast**.

```
. contrast {machine 3 -2 -2  3 -2}
>          {machine 0  1 -2  0  1}
>          {machine 1  0  0 -1  0}
>          {machine 0  1  0  0 -1}, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
machine			
(1)	1	0.75	0.4055
(2)	1	0.31	0.5916
(3)	1	4.47	0.0582
(4)	1	1.73	0.2150
Joint	4	1.93	0.1757
Residual	11		

`contrast` produces a 1-degree-of-freedom test for each of the specified contrasts as well as a joint test. We included the `noeffects` option so that the table displaying the values of the individual contrasts with their confidence intervals was suppressed.

The significance values above are not adjusted for multiple comparisons. We could have produced the Bonferroni-adjusted significance values by using the `mcompare(bonferroni)` option.

```
. contrast {machine 3 -2 -2  3 -2}
>          {machine 0  1 -2  0  1}
>          {machine 1  0  0 -1  0}
>          {machine 0  1  0  0 -1}, mcompare(bonferroni) noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F	Bonferroni P>F
machine				
(1)	1	0.75	0.4055	1.0000
(2)	1	0.31	0.5916	1.0000
(3)	1	4.47	0.0582	0.2329
(4)	1	1.73	0.2150	0.8601
Joint	4	1.93	0.1757	
Residual	11			

```
Note: Bonferroni-adjusted p-values are reported for tests
      on individual contrasts only.
```

◁

▷ Example 10

Here there are two factors, `A` and `B`, each with three levels. The levels are quantitative so that linear and quadratic contrasts are of interest.

```
. use http://www.stata-press.com/data/r12/twowaytrend
. anova Y A B A#B
```

Source	Partial SS	df	MS	F	Prob > F
Model	2578.55556	8	322.319444	45.09	0.0000
A	2026.72222	2	1013.36111	141.77	0.0000
B	383.722222	2	191.861111	26.84	0.0000
A#B	168.111111	4	42.0277778	5.88	0.0015
Residual	193	27	7.14814815		
Total	2771.55556	35	79.1873016		

Number of obs = 36 R-squared = 0.9304
Root MSE = 2.6736 Adj R-squared = 0.9097

We can use the `p.` contrast operator to obtain the 1-degree-of-freedom tests for the linear and quadratic effects of `A` and `B`.

```
. contrast p.A p.B, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
A			
(linear)	1	212.65	0.0000
(quadratic)	1	70.88	0.0000
Joint	2	141.77	0.0000
B			
(linear)	1	26.17	0.0000
(quadratic)	1	27.51	0.0000
Joint	2	26.84	0.0000
Residual	27		

All the above tests appear to be significant. In addition to presenting the 1-degree-of-freedom tests, the combined tests for `A` and `B` are produced and agree with the original ANOVA results.

Now we explore the interaction between `A` and `B`.

```
. contrast p.A#p1.B, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
A#B			
(linear) (linear)	1	17.71	0.0003
(quadratic) (linear)	1	0.07	0.7893
Joint	2	8.89	0.0011
Residual	27		

The 2-degrees-of-freedom test of the interaction of `A` with the linear components of `B` is significant at the 0.0011 level. But, when we examine the two 1-degree-of-freedom tests that compose this result,

the significance is due to the linear A by linear B contrast (significance level of 0.0003). A significance value of 0.7893 for the quadratic A by linear B indicates that this factor is not significant for these data.

```
. contrast p.A#p2.B, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
A#B			
(linear) (quadratic)	1	2.80	0.1058
(quadratic) (quadratic)	1	2.94	0.0979
Joint	2	2.87	0.0741
Residual	27		

The test of A with the quadratic components of B does not fall below the 0.05 significance level. ◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

areg — Linear regression with a large dummy-variable set

Syntax

`areg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] , `absorb(`*varname*`)` [*options*]

options	Description
Model	
* `absorb(`*varname*`)`	categorical variable to be absorbed
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `ols`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
`coeflegend`	display legend instead of statistics

*`absorb(`*varname*`)` is required.

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `jackknife`, `mi estimate`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`aweights`, `fweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Other > Linear regression absorbing one cat. variable

Description

`areg` fits a linear regression absorbing one categorical factor. `areg` is designed for datasets with many groups, but not a number of groups that increases with the sample size. See the `xtreg, fe` command in [XT] **xtreg** for an estimator that handles the case in which the number of groups increases with the sample size.

Options

Model

`absorb(`*varname*`)` specifies the categorical variable, which is to be included in the regression as if it were specified by dummy variables. `absorb()` is required.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(ols)`, the default, uses the standard variance estimator for ordinary least-squares regression.

Exercise caution when using the `vce(cluster` *clustvar*`)` option with `areg`. The effective number of degrees of freedom for the robust variance estimator is $n_g - 1$, where n_g is the number of clusters. Thus the number of levels of the `absorb()` variable should not exceed the number of clusters.

Reporting

`level(#)`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `areg` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Suppose that you have a regression model that includes among the explanatory variables a large number, k, of mutually exclusive and exhaustive dummies:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{d}_1\gamma_1 + \mathbf{d}_2\gamma_2 + \cdots + \mathbf{d}_k\gamma_k + \boldsymbol{\epsilon}$$

For instance, the dummy variables, $\mathbf{d}_i$, might indicate countries in the world or states of the United States. One solution would be to fit the model with `regress`, but this solution is possible only if k is small enough so that the total number of variables (the number of columns of $\mathbf{X}$ plus the number of $\mathbf{d}_i$'s plus one for $\mathbf{y}$) is sufficiently small—meaning less than `matsize` (see [R] **matsize**). For problems with more variables than the largest possible value of `matsize` (100 for Small Stata, 800 for Stata/IC, and 11,000 for Stata/SE and Stata/MP), `regress` will not work. `areg` provides a way of obtaining estimates of $\boldsymbol{\beta}$—but not the γ_i's—in these cases. The effects of the dummy variables are said to be absorbed.

▷ Example 1

So that we can compare the results produced by `areg` with Stata's other regression commands, we will fit a model in which k is small. `areg`'s real use, however, is when k is large.

In our automobile data, we have a variable called `rep78` that is coded 1, 2, 3, 4, and 5, where 1 means poor and 5 means excellent. Let's assume that we wish to fit a regression of `mpg` on `weight`, `gear_ratio`, and `rep78` (parameterized as a set of dummies).

```
. use http://www.stata-press.com/data/r12/auto

Both `regress` and `areg` display the same R^2 values, root mean squared error, and—for `weight` and `gear_ratio`—the same parameter estimates, standard errors, t statistics, significance levels, and confidence intervals. `areg`, however, does not report the coefficients for `rep78`, and, in fact, they are not even calculated. This computational trick makes the problem manageable when k is large. `areg` reports a test that the coefficients associated with `rep78` are jointly zero. Here this test has a significance level of 35.6%. This F test for `rep78` is the same that we would obtain after `regress` if we were to specify `test 1.rep78 2.rep78 3.rep78 4.rep78`; see [R] **test**.

The model F tests reported by `regress` and `areg` also differ. The `regress` command reports a test that all coefficients except that of the constant are equal to zero; thus, the dummies are included in this test. The `areg` output shows a test that all coefficients excluding the dummies and the constant are equal to zero. This is the same test that can be obtained after `regress` by typing `test weight gear_ratio`.

◁

❑ Technical note

areg is designed for datasets with many groups, but not a number that grows with the sample size. Consider two different samples from the U.S. population. In the first sample, we have 10,000 individuals and we want to include an indicator for each of the 50 states, whereas in the second sample we have 3 observations on each of 10,000 individuals and we want to include an indicator for each individual. areg was designed for datasets similar to the first sample in which we have a fixed number of groups, the 50 states. In the second sample, the number of groups, which is the number of individuals, grows as we include more individuals in the sample. For an estimator designed to handle the case in which the number of groups grows with the sample size, see the xtreg, fe command in [XT] **xtreg**.

Although the point estimates produced by areg and xtreg, fe are the same, the estimated VCEs differ when cluster() is specified because the commands make different assumptions about whether the number of groups increases with the sample size.

❑

❑ Technical note

The intercept reported by areg deserves some explanation because, given k mutually exclusive and exhaustive dummies, it is arbitrary. areg identifies the model by choosing the intercept that makes the prediction calculated at the means of the independent variables equal to the mean of the dependent variable: $\overline{\mathbf{y}} = \overline{\mathbf{x}}\,\widehat{\boldsymbol{\beta}}$.

```
. predict yhat
(option xb assumed; fitted values)
. summarize mpg yhat if rep78 != .
```

Variable	Obs	Mean	Std. Dev.	Min	Max
mpg	69	21.28986	5.866408	12	41
yhat	69	21.28986	4.383224	11.58643	28.07367

We had to include if rep78 < . in our summarize command because we have missing values in our data. areg automatically dropped those missing values (as it should) in forming the estimates, but predict with the xb option will make predictions for cases with missing rep78 because it does not know that rep78 is really part of our model.

These predicted values do not include the absorbed effects (that is, the $\mathbf{d}_i\gamma_i$). For predicted values that include these effects, use the xbd option of predict (see [R] **areg postestimation**) or see [XT] **xtreg**.

❑

▷ Example 2

areg, vce(robust) is a Huberized version of areg; see [P] **_robust**. Just as areg is equivalent to using regress with dummies, areg, vce(robust) is equivalent to using regress, vce(robust) with dummies. You can use areg, vce(robust) when you expect heteroskedastic or nonnormal errors. areg, vce(robust), like ordinary regression, assumes that the observations are independent, unless the vce(cluster *clustvar*) option is specified. If the vce(cluster *clustvar*) option is specified, this independence assumption is relaxed and only the clusters identified by equal values of *clustvar* are assumed to be independent.

Assume that we were to collect data by randomly sampling 10,000 doctors (from 100 hospitals) and then sampling 10 patients of each doctor, yielding a total dataset of 100,000 patients in a cluster sample. If in some regression we wished to include effects of the hospitals to which the doctors belonged, we would want to include a dummy variable for each hospital, adding 100 variables to our model. `areg` could fit this model by

```
. areg depvar patient_vars, absorb(hospital) vce(cluster doctor)
```

◁

Saved results

`areg` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(tss)`	total sum of squares
`e(df_m)`	model degrees of freedom
`e(rss)`	residual sum of squares
`e(df_r)`	residual degrees of freedom
`e(r2)`	R-squared
`e(r2_a)`	adjusted R-squared
`e(df_a)`	degrees of freedom for absorbed effect
`e(rmse)`	root mean squared error
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(F)`	F statistic
`e(F_absorb)`	F statistic for absorbed effect (when `vce(robust)` is not specified)
`e(rank)`	rank of `e(V)`

Macros

`e(cmd)`	`areg`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(absvar)`	name of `absorb` variable
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(clustvar)`	name of cluster variable
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(datasignature)`	the checksum
`e(datasignaturevars)`	variables used in calculation of checksum
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(marginsnotok)`	predictions disallowed by `margins`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

`e(b)`	coefficient vector
`e(Cns)`	constraints matrix
`e(V)`	variance–covariance matrix of the estimators
`e(V_modelbased)`	model-based variance

Functions

`e(sample)`	marks estimation sample

Methods and formulas

areg is implemented as an ado-file.

areg begins by recalculating *depvar* and *indepvars* to have mean 0 within the groups specified by absorb(). The overall mean of each variable is then added back in. The adjusted *depvar* is then regressed on the adjusted *indepvars* with regress, yielding the coefficient estimates. The degrees of freedom of the variance–covariance matrix of the coefficients is then adjusted to account for the absorbed variables—this calculation yields the same results (up to numerical roundoff error) as if the matrix had been calculated directly by the formulas given in [R] **regress**.

areg with vce(robust) or vce(cluster *clustvar*) works similarly, calling _robust after regress to produce the Huber/White/sandwich estimator of the variance or its clustered version. See [P] **_robust**, particularly *Introduction* and *Methods and formulas*. The model F test uses the robust variance estimates. There is, however, no simple computational means of obtaining a robust test of the absorbed dummies; thus this test is not displayed when the vce(robust) or vce(cluster *clustvar*) option is specified.

The number of groups specified in absorb() are included in the degrees of freedom used in the finite-sample adjustment of the cluster–robust VCE estimator. This statement is only valid if the number of groups is small relative to the sample size. (Technically, the number of groups must remain fixed as the sample size grows.) For an estimator that allows the number of groups to grow with the sample size, see the xtreg, fe command in [XT] **xtreg**.

Title

areg postestimation — Postestimation tools for areg

Description

The following postestimation commands are available after `areg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

where $y_j = \mathbf{x}_j\mathbf{b} + d_{\text{absorbvar}} + e_j$ and *statistic* is

statistic	Description
Main	
`xb`	$\mathbf{x}_j\mathbf{b}$, fitted values; the default
`stdp`	standard error of the prediction
`dresiduals`	$d_{\text{absorbvar}} + e_j = y_j - \mathbf{x}_j\mathbf{b}$
* `xbd`	$\mathbf{x}_j\mathbf{b} + d_{\text{absorbvar}}$
* `d`	$d_{\text{absorbvar}}$
* `residuals`	residual
* `score`	score; equivalent to `residuals`

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the prediction of $\mathbf{x}_j\mathbf{b}$, the fitted values, by using the average effect of the absorbed variable. Also see `xbd` below.

`stdp` calculates the standard error of $\mathbf{x}_j\mathbf{b}$.

`dresiduals` calculates $y_j - \mathbf{x}_j\mathbf{b}$, which are the residuals plus the effect of the absorbed variable.

`xbd` calculates $\mathbf{x}_j\mathbf{b} + d_{\text{absorbvar}}$, which are the fitted values including the individual effects of the absorbed variable.

`d` calculates $d_{\text{absorbvar}}$, the individual coefficients for the absorbed variable.

`residuals` calculates the residuals, that is, $y_j - (\mathbf{x}_j\mathbf{b} + d_{\text{absorbvar}})$.

`score` is a synonym for `residuals`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

asclogit — Alternative-specific conditional logit (McFadden's choice) model

Syntax

```
asclogit depvar [indepvars] [if] [in] [weight], case(varname)
    alternatives(varname) [options]
```

options	Description
Model	
* `case(`*varname*`)`	use *varname* to identify cases
* `alternatives(`*varname*`)`	use *varname* to identify the alternatives available for each case
`casevars(`*varlist*`)`	case-specific variables
`basealternative(`*# | lbl | str*`)`	alternative to normalize location
`noconstant`	suppress alternative-specific constant terms
`altwise`	use alternativewise deletion instead of casewise deletion
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`or`	report odds ratios
`noheader`	do not display the header on the coefficient table
`nocnsreport`	do not display constraints
display_options	control column formats and line width
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

* `case(`*varname*`)` and `alternatives(`*varname*`)` are required.

`bootstrap`, `by`, `jackknife`, `statsby`, and `xi` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`fweights`, `iweights`, and `pweights` are allowed (see [U] **11.1.6 weight**), but they are interpreted to apply to cases as a whole, not to individual observations. See *Use of weights* in [R] **clogit**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Categorical outcomes > Alternative-specific conditional logit

Description

`asclogit` fits McFadden's choice model, which is a specific case of the more general conditional logistic regression model (McFadden 1974). `asclogit` requires multiple observations for each case (individual or decision), where each observation represents an alternative that may be chosen. The cases are identified by the variable specified in the `case()` option, whereas the alternatives are identified by the variable specified in the `alternatives()` option. The outcome or chosen alternative is identified by a value of 1 in *depvar*, whereas zeros indicate the alternatives that were not chosen. There can be multiple alternatives chosen for each case.

`asclogit` allows two types of independent variables: alternative-specific variables and case-specific variables. Alternative-specific variables vary across both cases and alternatives and are specified in *indepvars*. Case-specific variables vary only across cases and are specified in the `casevars()` option.

See [R] **clogit** for a more general application of conditional logistic regression. For example, `clogit` would be used when you have grouped data where each observation in a group may be a different individual, but all individuals in a group have a common characteristic. You may use `clogit` to obtain the same estimates as `asclogit` by specifying the `case()` variable as the `group()` variable in `clogit` and generating variables that interact the `casevars()` in `asclogit` with each alternative (in the form of an indicator variable), excluding the interaction variable associated with the base alternative. `asclogit` takes care of this data-management burden for you. Also, for `clogit`, each record (row in your data) is an observation, whereas in `asclogit` each case, consisting of several records (the alternatives) in your data, is an observation. This last point is important because `asclogit` will drop observations, by default, in a casewise fashion. That is, if there is at least one missing value in any of the variables for each record of a case, the entire case is dropped from estimation. To use alternativewise deletion, specify the `altwise` option and only the records with missing values will be dropped from estimation.

Options

Model

`case(`*varname*`)` specifies the numeric variable that identifies each case. `case()` is required and must be integer valued.

`alternatives(`*varname*`)` specifies the variable that identifies the alternatives for each case. The number of alternatives can vary with each case; the maximum number of alternatives cannot exceed the limits of `tabulate oneway`; see [R] **tabulate oneway**. `alternatives()` is required and may be a numeric or a string variable.

`casevars(`*varlist*`)` specifies the case-specific numeric variables. These are variables that are constant for each case. If there are a maximum of J alternatives, there will be $J - 1$ sets of coefficients associated with the `casevars()`.

`basealternative(`*# | lbl | str*`)` specifies the alternative that normalizes the latent-variable location (the level of utility). The base alternative may be specified as a number, label, or string depending on the storage type of the variable indicating alternatives. The default is the alternative with the highest frequency.

If `vce(bootstrap)` or `vce(jackknife)` is specified, you must specify the base alternative. This is to ensure that the same model is fit with each call to `asclogit`.

`noconstant` suppresses the $J-1$ alternative-specific constant terms.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion; that is, the entire group of observations making up a case is deleted if any missing values are encountered. This option does not apply to observations that are marked out by the `if` or `in` qualifier or the `by` prefix.

`offset(`*varname*`)`, `constraints(`*numlist* | *matname*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`or` reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`noheader` prevents the coefficient table header from being displayed.

`nocnsreport`; see [R] **estimation options**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

`technique(bhhh)` is not allowed.

The initial estimates must be specified as `from(`*matname* `[ , copy ])`, where *matname* is the matrix containing the initial estimates and the `copy` option specifies that only the position of each element in *matname* is relevant. If `copy` is not specified, the column stripe of *matname* identifies the estimates.

The following option is available with `asclogit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

`asclogit` fits McFadden's choice model (McFadden [1974]; for a brief introduction, see Greene [2012, sec. 18.2] or Cameron and Trivedi [2010, sec. 15.5]). In this model, we have a set of unordered alternatives indexed by $1, 2, \ldots, J$. Let y_{ij}, $j = 1, \ldots, J$, be an indicator variable for the alternative actually chosen by the ith individual (case). That is, $y_{ij} = 1$ if individual i chose alternative j and $y_{ij} = 0$ otherwise. The independent variables come in two forms: alternative specific and case specific. Alternative-specific variables vary among the alternatives (as well as cases), and case-specific

variables vary only among cases. Assume that we have p alternative-specific variables so that for case i we have a $J \times p$ matrix, $\mathbf{X}_i$. Further, assume that we have q case-specific variables so that we have a $1 \times q$ vector $\mathbf{z}_i$ for case i. Our random-utility model can then be expressed as

$$\mathbf{u}_i = \mathbf{X}_i\boldsymbol{\beta} + (\mathbf{z}_i\mathbf{A})' + \boldsymbol{\epsilon}_i$$

Here $\boldsymbol{\beta}$ is a $p \times 1$ vector of alternative-specific regression coefficients and $\mathbf{A} = (\boldsymbol{\alpha}_1, \ldots, \boldsymbol{\alpha}_J)$ is a $q \times J$ matrix of case-specific regression coefficients. The elements of the $J \times 1$ vector $\boldsymbol{\epsilon}_i$ are independent Type I (Gumbel-type) extreme-value random variables with mean γ (the Euler–Mascheroni constant, approximately 0.577) and variance $\pi^2/6$. We must fix one of the $\boldsymbol{\alpha}_j$ to the constant vector to normalize the location. We set $\boldsymbol{\alpha}_k = 0$, where k is specified by the `basealternative()` option. The vector $\mathbf{u}_i$ quantifies the utility that the individual gains from the J alternatives. The alternative chosen by individual i is the one that maximizes utility.

▷ Example 1

We have data on 295 consumers and their choice of automobile. Each consumer chose among an American, Japanese, or European car; the variable `car` indicates the nationality of the car for each alternative. We want to explore the relationship between the choice of `car` to the consumer's sex (variable `sex`) and income (variable `income` in thousands of dollars). We also have information on the number of dealerships of each nationality in the consumer's city in the variable `dealer` that we want to include as a regressor. We assume that consumers' preferences are influenced by the number of dealerships in an area but that the number of dealerships is not influenced by consumer preferences (which we admit is a rather strong assumption). The variable `dealer` is an alternative-specific variable ($\mathbf{X}_i$ is a 3×1 vector in our previous notation), and `sex` and `income` are case-specific variables ($\mathbf{z}_i$ is a 1×2 vector). Each consumer's chosen car is indicated by the variable `choice`.

Let's list some of the data.

```
. use http://www.stata-press.com/data/r12/choice
. list id car choice dealer sex income in 1/12, sepby(id)
```

	id	car	choice	dealer	sex	income
1.	1	American	0	18	male	46.7
2.	1	Japan	0	8	male	46.7
3.	1	Europe	1	5	male	46.7
4.	2	American	1	17	male	26.1
5.	2	Japan	0	6	male	26.1
6.	2	Europe	0	2	male	26.1
7.	3	American	1	12	male	32.7
8.	3	Japan	0	6	male	32.7
9.	3	Europe	0	2	male	32.7
10.	4	American	0	18	female	49.2
11.	4	Japan	1	7	female	49.2
12.	4	Europe	0	4	female	49.2

We see, for example, that the first consumer, a male earning \$46,700 per year, chose to purchase a European car even though there are more American and Japanese car dealers in his area. The fourth consumer, a female earning \$49,200 per year, purchased a Japanese car.

We now fit our model.

```

_cons	.0948699	.0808925	-2.76	0.006	.0178376	.5045693

These results indicate that men (sex = 1) are less likely to pick a Japanese car over an American car than women (odds ratio 0.59) but that men are more likely to choose a European car over an American car (odds ratio 1.77). Raising a person's income increases the likelihood that he or she purchases a Japanese or European car; interestingly, the effect of higher income is about the same for these two types of cars.

◁

Daniel Little McFadden was born in 1937 in North Carolina. He studied physics, psychology, and economics at the University of Minnesota and has taught economics at Pittsburgh, Berkeley, MIT, and the University of Southern California. His contributions to logit models were triggered by a student's project on freeway routing decisions, and his work consistently links economic theory and applied problems. In 2000, he shared the Nobel Prize in Economics with James J. Heckman.

❑ Technical note

McFadden's choice model is related to multinomial logistic regression (see [R] **mlogit**). If all the independent variables are case specific, then the two models are identical. We verify this supposition by running the previous example without the alternative-specific variable, `dealer`.

```
. asclogit choice, case(id) alternatives(car) casevars(sex income) nolog
Alternative-specific conditional logit          Number of obs      =        885
Case variable: id                               Number of cases    =        295
Alternative variable: car                       Alts per case: min =          3
                                                               avg =        3.0
                                                               max =          3
                                                Wald chi2(4)      =      12.53
Log likelihood = -252.72012                     Prob > chi2       =     0.0138
```

To run `mlogit`, we must rearrange the dataset. `mlogit` requires a dependent variable that indicates the choice—1, 2, or 3—for each individual. We will use `car` as our dependent variable for those observations that represent the choice actually chosen.

```
. keep if choice == 1
(590 observations deleted)
. mlogit car sex income
Iteration 0:   log likelihood =  -259.1712
Iteration 1:   log likelihood = -252.81165
Iteration 2:   log likelihood = -252.72014
Iteration 3:   log likelihood = -252.72012
Multinomial logistic regression                 Number of obs   =        295
                                                LR chi2(4)      =      12.90
                                                Prob > chi2     =     0.0118
Log likelihood = -252.72012                     Pseudo R2       =     0.0249
```

car	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
American	(base outcome)					
Japan

The results are the same except for the model statistic: `asclogit` uses a Wald test and `mlogit` uses a likelihood-ratio test. If you prefer the likelihood-ratio test, you can fit the constant-only model for `asclogit` followed by the full model and use [R] **lrtest**. The following example will carry this out.

```
. use http://www.stata-press.com/data/r12/choice, clear
. asclogit choice, case(id) alternatives(car)
. estimates store null
. asclogit choice, case(id) alternatives(car) casevars(sex income)
. lrtest null .
```

❑

❑ Technical note

We force you to explicitly identify the case-specific variables in the `casevars()` option to ensure that the program behaves as you expect. For example, an `if` or `in` qualifier may drop observations in such a way that (what was expected to be) an alternative-specific variable turns into a case-specific variable. Here you would probably want `asclogit` to terminate instead of interacting the variable with the alternative indicators. This situation could also occur if `asclogit` drops cases, or observations if you use the `altwise` option, because of missing values.

❑

Saved results

asclogit saves the following in e():

Scalars

e(N)	number of observations
e(N_case)	number of cases
e(k)	number of parameters
e(k_alt)	number of alternatives
e(k_indvars)	number of alternative-specific variables
e(k_casevars)	number of case-specific variables
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(df_m)	model degrees of freedom
e(ll)	log likelihood
e(N_clust)	number of clusters
e(const)	constant indicator
e(i_base)	base alternative index
e(chi2)	χ^2
e(F)	F statistic
e(p)	significance
e(alt_min)	minimum number of alternatives
e(alt_avg)	average number of alternatives
e(alt_max)	maximum number of alternatives
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	asclogit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(indvars)	alternative-specific independent variable
e(casevars)	case-specific variables
e(case)	variable defining cases
e(altvar)	variable defining alternatives
e(alteqs)	alternative equation names
e(alt#)	alternative labels
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald, type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(datasignature)	the checksum
e(datasignaturevars)	variables used in calculation of checksum
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(stats)	alternative statistics
e(altvals)	alternative values
e(altfreq)	alternative frequencies
e(alt_casevars)	indicators for estimated case-specific coefficients—e(k_alt)×e(k_casevars)
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

asclogit is implemented as an ado-file.

In this model, we have a set of unordered alternatives indexed by $1, 2, \ldots, J$. Let y_{ij}, $j = 1, \ldots, J$, be an indicator variable for the alternative actually chosen by the ith individual (case). That is, $y_{ij} = 1$ if individual i chose alternative j and $y_{ij} = 0$ otherwise. The independent variables come in two forms: alternative specific and case specific. Alternative-specific variables vary among the alternatives (as well as cases), and case-specific variables vary only among cases. Assume that we have p alternative-specific variables so that for case i we have a $J \times p$ matrix, $\mathbf{X}_i$. Further, assume that we have q case-specific variables so that we have a $1 \times q$ vector $\mathbf{z}_i$ for case i. The deterministic component of the random-utility model can then be expressed as

$$\begin{aligned}\eta_i &= \mathbf{X}_i\boldsymbol{\beta} + (\mathbf{z}_i\mathbf{A})' \\ &= \mathbf{X}_i\boldsymbol{\beta} + (\mathbf{z}_i \otimes \mathbf{I}_J)\,\mathrm{vec}(\mathbf{A}') \\ &= (\mathbf{X}_i,\ \mathbf{z}_i \otimes \mathbf{I}_J)\begin{pmatrix}\boldsymbol{\beta} \\ \mathrm{vec}(\mathbf{A}')\end{pmatrix} \\ &= \mathbf{X}_i^*\boldsymbol{\beta}^*\end{aligned}$$

As before, $\boldsymbol{\beta}$ is a $p \times 1$ vector of alternative-specific regression coefficients, and $\mathbf{A} = (\boldsymbol{\alpha}_1, \ldots, \boldsymbol{\alpha}_J)$ is a $q \times J$ matrix of case-specific regression coefficients; remember that we must fix one of the $\boldsymbol{\alpha}_j$ to the constant vector to normalize the location. Here $\mathbf{I}_J$ is the $J \times J$ identity matrix, vec() is the vector function that creates a vector from a matrix by placing each column of the matrix on top of the other (see [M-5] **vec( )**), and $\otimes$ is the Kronecker product (see [M-2] **op_kronecker**).

We have rewritten the linear equation so that it is a form that can be used by clogit, namely, $\mathbf{X}_i^*\boldsymbol{\beta}^*$, where

$$\mathbf{X}_i^* = (\mathbf{X}_i,\ \mathbf{z}_i \otimes \mathbf{I}_J)$$

$$\boldsymbol{\beta}^* = \begin{pmatrix}\boldsymbol{\beta} \\ \mathrm{vec}(\mathbf{A}')\end{pmatrix}$$

With this in mind, see *Methods and formulas* in [R] **clogit** for the computational details of the conditional logit model.

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using vce(robust) and vce(cluster *clustvar*). See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. Specifying vce(robust) is equivalent to specifying vce(cluster *casevar*), where *casevar* is the variable that identifies the cases.

Title

asclogit postestimation — Postestimation tools for asclogit

Description

The following postestimation commands are of special interest after `asclogit`:

Commands	Description
`estat alternatives`	alternative summary statistics
`estat mfx`	marginal effects

For information about these commands, see below.

The following standard postestimation commands are also available:

Commands	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predicted probabilities, estimated linear predictor and its standard error
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation commands

`estat alternatives` displays summary statistics about the alternatives in the estimation sample.

`estat mfx` computes probability marginal effects.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]

predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
pr	probability that each alternative is chosen; the default
xb	linear prediction
stdp	standard error of the linear prediction

options	Description
Main	
*k(# | observed)	condition on # alternatives per case or on observed number of alternatives
altwise	use alternativewise deletion instead of casewise deletion when computing probabilities
nooffset	ignore the offset() variable specified in asclogit

*k(# | observed) may be used only with pr.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

pr computes the probability of choosing each alternative conditioned on each case choosing k() alternatives. This is the default statistic with default k(1); one alternative per case is chosen.

xb computes the linear prediction.

stdp computes the standard error of the linear prediction.

k(# | observed) conditions the probability on # alternatives per case or on the observed number of alternatives. The default is k(1). This option may be used only with the pr option.

altwise specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The xb and stdp options always use alternativewise deletion.

nooffset is relevant only if you specified offset(*varname*) for asclogit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}\boldsymbol{\beta}$ rather than as $\mathbf{x}\boldsymbol{\beta} + \text{offset}$.

scores calculates the scores for each coefficient in e(b). This option requires a new variable list of length equal to the number of columns in e(b). Otherwise, use the *stub** option to have predict generate enumerated variables with prefix *stub*.

Syntax for estat alternatives

```
estat alternatives
```

Menu

Statistics > Postestimation > Reports and statistics

Syntax for estat mfx

```
estat mfx [if] [in] [, options]
```

options	Description
Main	
varlist(*varlist*)	display marginal effects for *varlist*
at(mean [*atlist*] | median [*atlist*])	calculate marginal effects at these values
k(#)	condition on the number of alternatives chosen to be #
Options	
level(#)	set confidence interval level; default is level(95)
nodiscrete	treat indicator variables as continuous
noesample	do not restrict calculation of means and medians to the estimation sample
nowght	ignore weights when calculating means and medians

Menu

Statistics > Postestimation > Reports and statistics

Options for estat mfx

Main

varlist(*varlist*) specifies the variables for which to display marginal effects. The default is all variables.

at(mean [*atlist*] | median [*atlist*]) specifies the values at which the marginal effects are to be calculated. *atlist* is

[[*alternative*:*variable* = #] [*variable* = #] [*alternative*:*offset* = #] [...]]

The default is to calculate the marginal effects at the means of the independent variables by using the estimation sample, at(mean). If offset() is used during estimation, the means of the offsets (by alternative) are computed by default.

After specifying the summary statistic, you can specify a series of specific values for variables. You can specify values for alternative-specific variables by alternative, or you can specify one value for all alternatives. You can specify only one value for case-specific variables. You specify values for the offset() variable (if present) the same way as for alternative-specific variables. For example, in the choice dataset (car choice), income is a case-specific variable, whereas dealer is an alternative-specific variable. The following would be a legal syntax for estat mfx:

```
. estat mfx, at(mean American:dealer=18 income=40)
```

When `nodiscrete` is not specified, `at(mean` [*atlist*]`)` or `at(median` [*atlist*]`)` has no effect on computing marginal effects for indicator variables, which are calculated as the discrete change in the simulated probability as the indicator variable changes from 0 to 1.

The mean and median computations respect any `if` or `in` qualifiers, so you can restrict the data over which the statistic is computed. You can even restrict the values to a specific case, for example,

```
. estat mfx if case==21
```

`k(#)` computes the probabilities conditioned on # alternatives chosen. The default is one alternative chosen.

Options

`level(#)` sets the confidence level; default is `level(95)`.

`nodiscrete` specifies that indicator variables be treated as continuous variables. An indicator variable is one that takes on the value 0 or 1 in the estimation sample. By default, the discrete change in the simulated probability is computed as the indicator variable changes from 0 to 1.

`noesample` specifies that the whole dataset be considered instead of only those marked in the `e(sample)` defined by the `asclogit` command.

`nowght` specifies that weights be ignored when calculating the medians.

Remarks

Remarks are presented under the following headings:

Predicted probabilities
Obtaining estimation statistics

Predicted probabilities

After fitting a McFadden's choice model with alternative-specific conditional logistic regression, you can use `predict` to obtain the estimated probability of alternative choices given case profiles.

▷ Example 1

In example 1 of [R] **asclogit**, we fit a model of consumer choice of automobile. The alternatives are nationality of the automobile manufacturer: American, Japanese, or European. There is one alternative-specific variable in the model, `dealer`, which contains the number of dealerships of each nationality in the consumer's city. The case-specific variables are `sex`, the consumer's sex, and `income`, the consumer's income in thousands of dollars.

```
. use http://www.stata-press.com/data/r12/choice
. asclogit choice dealer, case(id) alternatives(car) casevars(sex income)
  (output omitted)
. predict p
(option pr assumed; Pr(car))
. predict p2, k(2)
(option pr assumed; Pr(car))
. format p p2 %6.4f
```

```
. list car choice dealer sex income p p2 in 1/9, sepby(id)
```

	car	choice	dealer	sex	income	p	p2
1.	American	0	18	male	46.7	0.6025	0.8589
2.	Japan	0	8	male	46.7	0.2112	0.5974
3.	Europe	1	5	male	46.7	0.1863	0.5437
4.	American	1	17	male	26.1	0.7651	0.9293
5.	Japan	0	6	male	26.1	0.1282	0.5778
6.	Europe	0	2	male	26.1	0.1067	0.4929
7.	American	1	12	male	32.7	0.6519	0.8831
8.	Japan	0	6	male	32.7	0.1902	0.5995
9.	Europe	0	2	male	32.7	0.1579	0.5174

◁

Obtaining estimation statistics

Here we will demonstrate the specialized `estat` subcommands after `asclogit`. Use `estat alternatives` to obtain a table of alternative statistics. The table will contain the alternative values, labels (if any), the number of cases in which each alternative is present, the frequency that the alternative is selected, and the percent selected.

Use `estat mfx` to obtain marginal effects after `asclogit`.

▷ Example 2

We will continue with the automobile choice example, where we first list the alternative statistics and then compute the marginal effects at the mean income in our sample, assuming that there are five automobile dealers for each nationality. We will evaluate the probabilities for females because `sex` is coded 0 for females, and we will be obtaining the discrete change from 0 to 1.

```
. estat alternatives
    Alternatives summary for car
```

index	Alternative value	label	Cases present	Frequency selected	Percent selected
1	1	American	295	192	65.08
2	2	Japan	295	64	21.69
3	3	Europe	295	39	13.22

```
. estat mfx, at(dealer=0 sex=0) varlist(sex income)
Pr(choice = American|1 selected) = .41964329
```

variable	dp/dx	Std. Err.	z	P>|z|	[95% C.I.]		X
casevars							
sex*	.026238	.068311	0.38	0.701	-.107649	.160124	0
income	-.007891	.002674	-2.95	0.003	-.013132	-.00265	42.097

(*) dp/dx is for discrete change of indicator variable from 0 to 1

```
Pr(choice = Japan|1 selected) = .42696187
```

variable	dp/dx	Std. Err.	z	P>|z|	[95% C.I.]		X
casevars							
sex*	-.161164	.079238	-2.03	0.042	-.316468	-.005859	0
income	.005861	.002997	1.96	0.051	-.000014	.011735	42.097

```
(*) dp/dx is for discrete change of indicator variable from 0 to 1
Pr(choice = Europe|1 selected) = .15339484
```

variable	dp/dx	Std. Err.	z	P>|z|	[95% C.I.]		X
casevars							
sex*	.134926	.076556	1.76	0.078	-.015122	.284973	0
income	.00203	.001785	1.14	0.255	-.001469	.00553	42.097

```
(*) dp/dx is for discrete change of indicator variable from 0 to 1
```

The marginal effect of `income` indicates that there is a lower chance for a consumer to buy American automobiles with an increase in income. There is an indication that men have a higher preference for European automobiles than women but a lower preference for Japanese automobiles. We did not include the marginal effects for `dealer` because we view these as nuisance parameters, so we adjusted the probabilities by fixing dealer to a constant, 0.

◁

Saved results

`estat mfx` saves the following in `r()`:

Scalars

`r(pr_`*alt*`)` scalars containing the computed probability of each alternative evaluated at the value that is labeled X in the table output. Here *alt* are the labels in the macro `e(alteqs)`.

Matrices

`r(`*alt*`)` matrices containing the computed marginal effects and associated statistics. There is one matrix for each alternative, where *alt* are the labels in the macro `e(alteqs)`. Column 1 of each matrix contains the marginal effects; column 2, their standard errors; column 3, their z statistics; and columns 4 and 5, the confidence intervals. Column 6 contains the values of the independent variables used to compute the probabilities `r(pr_`*alt*`)`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

The deterministic component of the random-utility model can be expressed as

$$\begin{aligned}\boldsymbol{\eta} &= \mathbf{X}\boldsymbol{\beta} + (\mathbf{z}\mathbf{A})' \\ &= \mathbf{X}\boldsymbol{\beta} + (\mathbf{z} \otimes \mathbf{I}_J)\,\mathrm{vec}(\mathbf{A}') \\ &= (\mathbf{X},\ \mathbf{z} \otimes \mathbf{I}_J) \begin{pmatrix} \boldsymbol{\beta} \\ \mathrm{vec}(\mathbf{A}') \end{pmatrix} \\ &= \mathbf{X}^*\boldsymbol{\beta}^*\end{aligned}$$

where $\mathbf{X}$ is the $J \times p$ matrix containing the alternative-specific covariates, $\mathbf{z}$ is a $1 \times q$ vector of case-specific variables, $\boldsymbol{\beta}$ is a $p \times 1$ vector of alternative-specific regression coefficients, and $\mathbf{A} = (\boldsymbol{\alpha}_1, \ldots, \boldsymbol{\alpha}_J)$ is a $q \times J$ matrix of case-specific regression coefficients (with one of the $\boldsymbol{\alpha}_j$ fixed to the constant). Here $\mathbf{I}_J$ is the $J \times J$ identity matrix, vec() is the vector function that creates a vector from a matrix by placing each column of the matrix on top of the other (see [M-5] **vec( )**), and $\otimes$ is the Kronecker product (see [M-2] **op_kronecker**).

We have rewritten the linear equation so that it is a form that we all recognize, namely, $\boldsymbol{\eta} = \mathbf{X}^*\boldsymbol{\beta}^*$, where

$$\mathbf{X}^* = (\mathbf{X},\ \mathbf{z} \otimes \mathbf{I}_J)$$

$$\boldsymbol{\beta}^* = \begin{pmatrix} \boldsymbol{\beta} \\ \mathrm{vec}(\mathbf{A}') \end{pmatrix}$$

To compute the marginal effects, we use the derivative of the log likelihood $\partial\ell(\mathbf{y}|\boldsymbol{\eta})/\partial\boldsymbol{\eta}$, where $\ell(\mathbf{y}|\boldsymbol{\eta}) = \log \Pr(\mathbf{y}|\boldsymbol{\eta})$ is the log of the probability of the choice indicator vector $\mathbf{y}$ given the linear predictor vector $\boldsymbol{\eta}$. Namely,

$$\begin{aligned}\frac{\partial \Pr(\mathbf{y}|\boldsymbol{\eta})}{\partial \mathrm{vec}(\mathbf{X}^*)'} &= \Pr(\mathbf{y}|\boldsymbol{\eta}) \frac{\partial \ell(\mathbf{y}|\boldsymbol{\eta})}{\partial \boldsymbol{\eta}'} \frac{\partial \boldsymbol{\eta}}{\partial \mathrm{vec}(\mathbf{X}^*)'} \\ &= \Pr(\mathbf{y}|\boldsymbol{\eta}) \frac{\partial \ell(\mathbf{y}|\boldsymbol{\eta})}{\partial \boldsymbol{\eta}'} \left(\boldsymbol{\beta}^{*\prime} \otimes \mathbf{I}_J\right)\end{aligned}$$

The standard errors of the marginal effects are computed using the delta method.

Title

asmprobit — Alternative-specific multinomial probit regression

Syntax

```
asmprobit depvar [indepvars] [if] [in] [weight], case(varname)
    alternatives(varname) [options]
```

options	Description
Model	
* `case(`*varname*`)`	use *varname* to identify cases
* `alternatives(`*varname*`)`	use *varname* to identify the alternatives available for each case
`casevars(`*varlist*`)`	case-specific variables
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
Model 2	
`correlation(`*correlation*`)`	correlation structure of the latent-variable errors
`stddev(`*stddev*`)`	variance structure of the latent-variable errors
`structural`	use the structural covariance parameterization; default is the differenced covariance parameterization
`factor(#)`	use the factor covariance structure with dimension #
`noconstant`	suppress the alternative-specific constant terms
`basealternative(`*# | lbl | str*`)`	alternative used for normalizing location
`scalealternative(`*# | lbl | str*`)`	alternative used for normalizing scale
`altwise`	use alternativewise deletion instead of casewise deletion
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`notransform`	do not transform variance–covariance estimates to the standard deviation and correlation metric
`nocnsreport`	do not display constraints
display_options	control column formats and line width

Integration

`intmethod(`*seqtype*`)`	type of quasi- or pseudouniform point set
`intpoints(#)`	number of points in each sequence
`intburn(#)`	starting index in the Hammersley or Halton sequence
`intseed(`*code*`|#)`	pseudouniform random-number seed
`antithetics`	use antithetic draws
`nopivot`	do not use integration interval pivoting
`initbhhh(#)`	use the BHHH optimization algorithm for the first # iterations
`favor(speed|space)`	favor speed or space when generating integration points

Maximization

maximize_options	control the maximization process
`coeflegend`	display legend instead of statistics

correlation	Description
`unstructured`	one correlation parameter for each pair of alternatives; correlations with the `basealternative()` are zero; the default
`exchangeable`	one correlation parameter common to all pairs of alternatives; correlations with the `basealternative()` are zero
`independent`	constrain all correlation parameters to zero
`pattern` *matname*	user-specified matrix identifying the correlation pattern
`fixed` *matname*	user-specified matrix identifying the fixed and free correlation parameters

stddev	Description
`heteroskedastic`	estimate standard deviation for each alternative; standard deviations for `basealternative()` and `scalealternative()` set to one
`homoskedastic`	all standard deviations are one
`pattern` *matname*	user-specified matrix identifying the standard deviation pattern
`fixed` *matname*	user-specified matrix identifying the fixed and free standard deviations

seqtype	Description
`hammersley`	Hammersley point set
`halton`	Halton point set
`random`	uniform pseudorandom point set

*`case(`*varname*`)` and `alternatives(`*varname*`)` are required.
`bootstrap`, `by`, `jackknife`, `statsby`, and `xi` are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Statistics > Categorical outcomes > Alternative-specific multinomial probit

Description

`asmprobit` fits multinomial probit (MNP) models by using maximum simulated likelihood (MSL) implemented by the Geweke–Hajivassiliou–Keane (GHK) algorithm. By estimating the variance–covariance parameters of the latent-variable errors, the model allows you to relax the independence of irrelevant alternatives (IIA) property that is characteristic of the multinomial logistic model.

`asmprobit` requires multiple observations for each case (decision), where each observation represents an alternative that may be chosen. The cases are identified by the variable specified in the `case()` option, whereas the alternatives are identified by the variable specified in the `alternative()` option. The outcome (chosen alternative) is identified by a value of 1 in *depvar*, with 0 indicating the alternatives that were not chosen; only one alternative may be chosen for each case.

`asmprobit` allows two types of independent variables: alternative-specific variables and case-specific variables. Alternative-specific variables vary across both cases and alternatives and are specified in *indepvars*. Case-specific variables vary only across cases and are specified in the `casevars()` option.

Options

Model

`case(`*varname*`)` specifies the variable that identifies each case. This variable identifies the individuals or entities making a choice. `case()` is required.

`alternatives(`*varname*`)` specifies the variable that identifies the alternatives for each case. The number of alternatives can vary with each case; the maximum number of alternatives is 20. `alternatives()` is required.

`casevars(`*varlist*`)` specifies the case-specific variables that are constant for each `case()`. If there are a maximum of J alternatives, there will be $J-1$ sets of coefficients associated with `casevars()`.

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

Model 2

`correlation(`*correlation*`)` specifies the correlation structure of the latent-variable errors.

`correlation(unstructured)` is the most general and has $J(J-3)/2+1$ unique correlation parameters. This is the default unless `stdev()` or `structural` are specified.

`correlation(exchangeable)` provides for one correlation coefficient common to all latent variables, except the latent variable associated with the `basealternative()` option.

`correlation(independent)` assumes that all correlations are zero.

`correlation(pattern` *matname*`)` and `correlation(fixed` *matname*`)` give you more flexibility in defining the correlation structure. See *Variance structures* later in this entry for more information.

`stddev(`*stddev*`)` specifies the variance structure of the latent-variable errors.

`stddev(heteroskedastic)` is the most general and has $J-2$ estimable parameters. The standard deviations of the latent-variable errors for the alternatives specified in `basealternative()` and `scalealternative()` are fixed to one.

`stddev(homoskedastic)` constrains all the standard deviations to equal one.

`stddev(pattern` *matname*`)` and `stddev(fixed` *matname*`)` give you added flexibility in defining the standard deviation parameters. See *Variance structures* later in this entry for more information.

`structural` requests the $J \times J$ structural covariance parameterization instead of the default $J-1 \times J-1$ differenced covariance parameterization (the covariance of the latent errors differenced with that of the base alternative). The differenced covariance parameterization will achieve the same MSL regardless of the choice of `basealternative()` and `scalealternative()`. On the other hand, the structural covariance parameterization imposes more normalizations that may bound the model away from its maximum likelihood and thus prevent convergence with some datasets or choices of `basealternative()` and `scalealternative()`.

`factor(#)` requests that the factor covariance structure of dimension # be used. The `factor()` option can be used with the `structural` option but cannot be used with `stddev()` or `correlation()`. A $\# \times J$ (or $\# \times J-1$) matrix, $\mathbf{C}$, is used to factor the covariance matrix as $I + \mathbf{C}'\mathbf{C}$, where I is the identity matrix of dimension J (or $J-1$). The column dimension of $\mathbf{C}$ depends on whether the covariance is structural or differenced. The row dimension of $\mathbf{C}$, #, must be less than or equal to `floor(`$(J(J-1)/2-1)/(J-2)$`)`, because there are only $J(J-1)/2-1$ identifiable variance–covariance parameters. This covariance parameterization may be useful for reducing the number of covariance parameters that need to be estimated.

If the covariance is structural, the column of $\mathbf{C}$ corresponding to the base alternative contains zeros. The column corresponding to the scale alternative has a one in the first row and zeros elsewhere. If the covariance is differenced, the column corresponding to the scale alternative (differenced with the base) has a one in the first row and zeros elsewhere.

`noconstant` suppresses the $J-1$ alternative-specific constant terms.

`basealternative(#` | *lbl* | *str*`)` specifies the alternative used to normalize the latent-variable location (also referred to as the level of utility). The base alternative may be specified as a number, label, or string. The standard deviation for the latent-variable error associated with the base alternative is fixed to one, and its correlations with all other latent-variable errors are set to zero. The default is the first alternative when sorted. If a `fixed` or `pattern` matrix is given in the `stddev()` and `correlation()` options, the `basealternative()` will be implied by the fixed standard deviations and correlations in the matrix specifications. `basealternative()` cannot be equal to `scalealternative()`.

`scalealternative(#` | *lbl* | *str*`)` specifies the alternative used to normalize the latent-variable scale (also referred to as the scale of utility). The scale alternative may be specified as a number, label, or string. The default is to use the second alternative when sorted. If a `fixed` or `pattern` matrix is given in the `stddev()` option, the `scalealternative()` will be implied by the fixed standard deviations in the matrix specification. `scalealternative()` cannot be equal to `basealternative()`.

If a `fixed` or `pattern` matrix is given for the `stddev()` option, the base alternative and scale alternative are implied by the standard deviations and correlations in the matrix specifications, and they need not be specified in the `basealternative()` and `scalealternative()` options.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion; that is, the entire group of observations making up a case is deleted if any missing values are encountered. This option does not apply to observations that are marked out by the `if` or `in` qualifier or the `by` prefix.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `basealternative()` and `scalealternative()`.

Reporting

`level(#)`; see [R] **estimation options**.

`notransform` prevents retransforming the Cholesky-factored variance–covariance estimates to the correlation and standard deviation metric.

This option has no effect if `structural` is not specified because the default differenced variance–covariance estimates have no interesting interpretation as correlations and standard deviations. `notransform` also has no effect if the `correlation()` and `stddev()` options are specified with anything other than their default values. Here it is generally not possible to factor the variance–covariance matrix, so optimization is already performed using the standard deviation and correlation representations.

`nocnsreport`; see [R] **estimation options**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Integration

`intmethod(hammersley | halton | random)` specifies the method of generating the point sets used in the quasi–Monte Carlo integration of the multivariate normal density. `intmethod(hammersley)`, the default, uses the Hammersley sequence; `intmethod(halton)` uses the Halton sequence; and `intmethod(random)` uses a sequence of uniform random numbers.

`intpoints(#)` specifies the number of points to use in the quasi–Monte Carlo integration. If this option is not specified, the number of points is $50 \times J$ if `intmethod(hammersley)` or `intmethod(halton)` is used and $100 \times J$ if `intmethod(random)` is used. Larger values of `intpoints()` provide better approximations of the log likelihood, but at the cost of added computation time.

`intburn(#)` specifies where in the Hammersley or Halton sequence to start, which helps reduce the correlation between the sequences of each dimension. The default is 0. This option may not be specified with `intmethod(random)`.

`intseed(`*code* | `#)` specifies the seed to use for generating the uniform pseudorandom sequence. This option may be specified only with `intmethod(random)`. *code* refers to a string that records the state of the random-number generator `runiform()`; see [R] **set seed**. An integer value # may be used also. The default is to use the current seed value from Stata's uniform random-number generator, which can be obtained from `c(seed)`.

`antithetics` specifies that antithetic draws be used. The antithetic draw for the $J - 1$ vector uniform-random variables, $\mathbf{x}$, is $1 - \mathbf{x}$.

`nopivot` turns off integration interval pivoting. By default, `asmprobit` will pivot the wider intervals of integration to the interior of the multivariate integration. This improves the accuracy of the quadrature estimate. However, discontinuities may result in the computation of numerical second-order derivatives using finite differencing (for the Newton–Raphson optimize technique, `tech(nr)`) when few simulation points are used, resulting in a non–positive-definite Hessian. `asmprobit`

uses the Broyden–Fletcher–Goldfarb–Shanno optimization algorithm, by default, which does not require computing the Hessian numerically using finite differencing.

`initbhhh(#)` specifies that the Berndt–Hall–Hall–Hausman (BHHH) algorithm be used for the initial # optimization steps. This option is the only way to use the BHHH algorithm along with other optimization techniques. The algorithm switching feature of `ml`'s `technique()` option cannot include `bhhh`.

`favor(speed|space)` instructs `asmprobit` to favor either speed or space when generating the integration points. `favor(speed)` is the default. When favoring speed, the integration points are generated once and stored in memory, thus increasing the speed of evaluating the likelihood. This speed increase can be seen when there are many cases or when the user specifies a large number of integration points, `intpoints(#)`. When favoring space, the integration points are generated repeatedly with each likelihood evaluation.

For unbalanced data, where the number of alternatives varies with each case, the estimates computed using `intmethod(random)` will vary slightly between `favor(speed)` and `favor(space)`. This is because the uniform sequences will not be identical, even when initiating the sequences using the same uniform seed, `intseed(`*code*`|#)`. For `favor(speed)`, `ncase` blocks of `intpoints(#)` $\times$ $J-2$ uniform points are generated, where J is the maximum number of alternatives. For `favor(space)`, the column dimension of the matrices of points varies with the number of alternatives that each case has.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**.

The following options may be particularly useful in obtaining convergence with `asmprobit`: `difficult`, `technique(`*algorithm_spec*`)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`.

If `technique()` contains more than one algorithm specification, `bhhh` cannot be one of them. To use the BHHH algorithm with another algorithm, use the `initbhhh()` option and specify the other algorithm in `technique()`.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `asmprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Variance structures

Introduction

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms are assumed to have a multivariate normal distribution that is heteroskedastic and correlated. Say that you have a set of J unordered

alternatives that are modeled by a regression of both case-specific and alternative-specific covariates. A "case" refers to the information on one decision maker. Underlying the model is the set of J latent variables (utilities),

$$\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij} \tag{1}$$

where i denotes cases and j denotes alternatives. $\mathbf{x}_{ij}$ is a $1 \times p$ vector of alternative-specific variables, $\boldsymbol{\beta}$ is a $p \times 1$ vector of parameters, $\mathbf{z}_i$ is a $1 \times q$ vector of case-specific variables, $\boldsymbol{\alpha}_j$ is a $q \times 1$ vector of parameters for the jth alternative, and $\xi_i = (\xi_{i1}, \ldots, \xi_{iJ})$ is distributed multivariate normal with mean zero and covariance matrix $\boldsymbol{\Omega}$. The decision maker selects the alternative whose latent variable is highest.

Because the MNP model allows for a general covariance structure in ξ_{ij}, it does not impose the IIA property inherent in multinomial logistic and conditional logistic models. That is, the MNP model permits the odds of choosing one alternative over another to depend on the remaining alternatives. For example, consider the choice of travel mode between two cities: air, train, bus, or car, as a function of the travel mode cost, travel time (alternative-specific variables), and an individual's income (a case-specific variable). The odds of choosing air travel over a bus may not be independent of the train alternative because both bus and train travel are public ground transportation. That is, the probability of choosing air travel is $\Pr(\eta_{\text{air}} > \eta_{\text{bus}}, \eta_{\text{air}} > \eta_{\text{train}}, \eta_{\text{air}} > \eta_{\text{car}})$, and the two events $\eta_{\text{air}} > \eta_{\text{bus}}$ and $\eta_{\text{air}} > \eta_{\text{train}}$ may be correlated.

An alternative to MNP that will allow a nested correlation structure in ξ_{ij} is the nested logit model (see [R] **nlogit**).

The added flexibility of the MNP model does impose a significant computation burden because of the need to evaluate probabilities from the multivariate normal distribution. These probabilities are evaluated using simulation techniques because a closed-form solution does not exist. See *Methods and formulas* for more information.

Not all the J sets of regression coefficients $\boldsymbol{\alpha}_j$ are identifiable, nor are all $J(J+1)/2$ elements of the variance–covariance matrix $\boldsymbol{\Omega}$. As described by Train (2009, sec. 2.5), the model requires normalization because both the location (level) and scale of the latent variable are irrelevant. Increasing the latent variables by a constant does not change which η_{ij} is the maximum for decision maker i, nor does multiplying them by a constant. To normalize location, we choose an alternative, indexed by k, say, and take the difference between the latent variable k and the $J-1$ others,

$$\begin{aligned} v_{ijk} &= \eta_{ij} - \eta_{ik} \\ &= (\mathbf{x}_{ij} - \mathbf{x}_{ik})\boldsymbol{\beta} + \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \boldsymbol{\delta}_{ij'}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \\ &= \lambda_{ij'} + \epsilon_{ij'} \end{aligned} \tag{2}$$

where $j' = j$ if $j < k$ and $j' = j-1$ if $j > k$, so that $j' = 1, \ldots, J-1$. One can now work with the $(J-1) \times (J-1)$ covariance matrix $\boldsymbol{\Sigma}_{(k)}$ for $\boldsymbol{\epsilon}_i' = (\epsilon_{i1}, \ldots, \epsilon_{i,J-1})$. The kth alternative here is the `basealternative()` in `asmprobit`. From (2), the probability that decision maker i chooses alternative k, for example, is

$$\begin{aligned} \Pr(i \text{ chooses } k) &= \Pr(v_{i1k} \le 0, \ldots, v_{i,J-1,k} \le 0) \\ &= \Pr(\epsilon_{i1} \le -\lambda_{i1}, \ldots, \epsilon_{i,J-1} \le -\lambda_{i,J-1}) \end{aligned}$$

To normalize for scale, one of the diagonal elements of $\boldsymbol{\Sigma}_{(k)}$ must be fixed to a constant. In `asmprobit`, this is the error variance for the alternative specified by `scalealternative()`. Thus there are a total of, at most, $J(J-1)/2-1$ identifiable variance–covariance parameters. See *Variance structures* below for more on this issue.

In fact, the model is slightly more general in that not all cases need to have faced all J alternatives. The model allows for situations in which some cases chose among all possible alternatives, whereas other cases were given a choice among a subset of them, and perhaps other cases were given a choice among a different subset. The number of observations for each case is equal to the number of alternatives faced.

The MNP model is often motivated using a random-utility consumer-choice framework. Equation (1) represents the utility that consumer i receives from good j. The consumer purchases the good for which the utility is highest. Because utility is ordinal, all that matters is the ranking of the utilities from the alternatives. Thus one must normalize for location and scale.

▷ Example 1

Application of MNP models is common in the analysis of transportation data. Greene (2012, sec. 18.2.9) uses travel-mode choice data between Sydney and Melbourne to demonstrate estimating parameters of various discrete-choice models. The data contain information on 210 individuals' choices of travel mode. The four alternatives are air, train, bus, and car, with indices 1, 2, 3, and 4, respectively. One alternative-specific variable is `travelcost`, a measure of generalized cost of travel that is equal to the sum of in-vehicle cost and a wagelike measure times the amount of time spent traveling. A second alternative-specific variable is the terminal time, `termtime`, which is zero for car transportation. Household income, `income`, is a case-specific variable.

```
. use http://www.stata-press.com/data/r12/travel
. list id mode choice travelcost termtime income in 1/12, sepby(id)
```

	id	mode	choice	travel~t	termtime	income
1.	1	air	0	70	69	35
2.	1	train	0	71	34	35
3.	1	bus	0	70	35	35
4.	1	car	1	30	0	35
5.	2	air	0	68	64	30
6.	2	train	0	84	44	30
7.	2	bus	0	85	53	30
8.	2	car	1	50	0	30
9.	3	air	0	129	69	40
10.	3	train	0	195	34	40
11.	3	bus	0	149	35	40
12.	3	car	1	101	0	40

The model of travel choice is

$$\eta_{ij} = \beta_1 \texttt{travelcost}_{ij} + \beta_2 \texttt{termtime}_{ij} + \alpha_{1j} \texttt{income}_i + \alpha_{0j} + \xi_{ij}$$

The alternatives can be grouped as air and ground travel. With this in mind, we set the `air` alternative to be the `basealternative()` and choose `train` as the scaling alternative. Because these are the first and second alternatives in the `mode` variable, they are also the defaults.

```
. asmprobit choice travelcost termtime, case(id) alternatives(mode)
> casevars(income)
```

(*output omitted*)

```

```

By default, the differenced covariance parameterization is used, so the covariance matrix for this model is 3×3. There are two free variances to estimate and three correlations. To help ensure that the covariance matrix remains positive definite, `asmprobit` uses the square root transformation, where it optimizes on the Cholesky-factored variance–covariance. To ensure that the diagonal elements of the Cholesky estimates remain positive, we use the log transformation. The estimates labeled `/lnl2_2` and `/lnl3_3` in the coefficient table are the log-transformed diagonal elements of the Cholesky matrix. The estimates labeled `/l2_1`, `/l3_1`, and `/l3_2` are the off-diagonal entries for elements $(2, 1)$, $(3, 1)$, and $(3, 2)$ of the Cholesky matrix.

Although the transformed parameters of the differenced covariance parameterization are difficult to interpret, you can view them untransformed by using the `estat` command. Typing

```
. estat correlation
```

	train	bus	car
train	1.0000		
bus	0.8909	1.0000	
car	0.7895	0.8951	1.0000

```
Note: correlations are for alternatives differenced with air
```

gives the correlations, and typing

```
. estat covariance
```

	train	bus	car
train	2		
bus	1.600208	1.613068	
car	1.37471	1.399703	1.515884

```
Note: covariances are for alternatives differenced with air
```

gives the (co)variances.

We can reduce the number of covariance parameters in the model by using the factor model by Cameron and Trivedi (2005). For large models with many alternatives, the parameter reduction can be dramatic, but for our example we will use `factor(1)`, a one-dimension factor model, to reduce by 3 the number of parameters associated with the covariance matrix.

◁

Variance structures

The matrix $\mathbf{\Omega}$ has $J(J+1)/2$ distinct elements because it is symmetric. Selecting a base alternative, normalizing its error variance to one, and constraining the correlations between its error and the other errors reduces the number of estimable parameters by J. Moreover, selecting a scale alternative and normalizing its error variance to one reduces the number by one, as well. Hence, there are at most $m = J(J-1)/2 - 1$ estimable parameters in $\mathbf{\Omega}$.

In practice, estimating all m parameters can be difficult, so one must often place more restrictions on the parameters. The `asmprobit` command provides the `correlation()` option to specify restrictions on the $J(J-3)/2+1$ correlation parameters not already restricted as a result of choosing the base alternatives, and it provides `stddev()` to specify restrictions on the $J-2$ standard deviations not already restricted as a result of choosing the base and scale alternatives.

When the `structural` option is used, `asmprobit` fits the model by assuming that all m parameters can be estimated, which is equivalent to specifying `correlation(unstructured)` and `stddev(heteroskedastic)`. The unstructured correlation structure means that all $J(J-3)/2+1$ of the remaining correlation parameters will be estimated, and the heteroskedastic specification means that all $J-2$ standard deviations will be estimated. With these default settings, the log likelihood is maximized with respect to the Cholesky decomposition of $\boldsymbol{\Omega}$, and then the parameters are transformed to the standard deviation and correlation form.

The `correlation(exchangeable)` option forces the $J(J-3)/2+1$ correlation parameters to be equal, and `correlation(independent)` forces all the correlations to be zero. Using the `stddev(homoskedastic)` option forces all J standard deviations to be one. These options may help in obtaining convergence for a model if the default options do not produce satisfactory results. In fact, when fitting a complex model, it may be advantageous to first fit a simple one and then proceed with removing the restrictions one at a time.

Advanced users may wish to specify alternative variance structures of their own choosing, and the next few paragraphs explain how to do so.

`correlation(pattern` *matname*`)` allows you to give the name of a $J \times J$ matrix that identifies a correlation structure. Sequential positive integers starting at 1 are used to identify each correlation parameter: if there are three correlation parameters, they are identified by 1, 2, and 3. The integers can be repeated to indicate that correlations with the same number should be constrained to be equal. A zero or a missing value (`.`) indicates that the correlation is to be set to zero. `asmprobit` considers only the elements of the matrix *below* the main diagonal.

Suppose that you have a model with four alternatives, numbered 1–4, and alternative 1 is the base. The unstructured and exchangeable correlation structures identified in the 4×4 lower triangular matrices are

unstructured

	1	2	3	4
1	·			
2	0	·		
3	0	1	·	
4	0	2	3	·

exchangeable

	1	2	3	4
1	·			
2	0	·		
3	0	1	·	
4	0	1	1	·

`asmprobit` labels these correlation structures unstructured and exchangeable, even though the correlations corresponding to the base alternative are set to zero. More formally: these terms are appropriate when considering the $(J-1) \times (J-1)$ submatrix $\boldsymbol{\Sigma}_{(k)}$ defined in the *Introduction* above.

You can also use the `correlation(fixed` *matname*`)` option to specify a matrix that specifies fixed and free parameters. Here the free parameters (those that are to be estimated) are identified by a missing value, and nonmissing values represent correlations that are to be taken as given. Below is a correlation structure that would set the correlations of alternative 1 to be 0.5:

	1	2	3	4
1	·			
2	0.5	·		
3	0.5	·	·	
4	0.5	·	·	·

The order of the elements of the `pattern` or `fixed` matrices must be the same as the numeric order of the alternative levels.

To specify the structure of the standard deviations—the diagonal elements of $\boldsymbol{\Omega}$—you can use the `stddev(pattern` *matname*`)` option, where *matname* is a $1 \times J$ matrix. Sequential positive integers starting at 1 are used to identify each standard deviation parameter. The integers can be repeated to indicate that standard deviations with the same number are to be constrained to be equal. A missing value indicates that the corresponding standard deviation is to be set to one. In the four-alternative example mentioned above, suppose that you wish to set the first and second standard deviations to one and that you wish to constrain the third and fourth standard deviations to be equal; the following `pattern` matrix will do that:

$$\begin{array}{c} \\ 1 \end{array} \begin{array}{c} \begin{array}{cccc} 1 & 2 & 3 & 4 \end{array} \\ \begin{pmatrix} \cdot & \cdot & 1 & 1 \end{pmatrix} \end{array}$$

Using the `stddev(fixed` *matname*`)` option allows you to identify the fixed and free standard deviations. Fixed standard deviations are entered as positive real numbers, and free parameters are identified with missing values. For example, to constrain the first and second standard deviations to equal one and to allow the third and fourth to be estimated, you would use this `fixed` matrix:

$$\begin{array}{c} \\ 1 \end{array} \begin{array}{c} \begin{array}{cccc} 1 & 2 & 3 & 4 \end{array} \\ \begin{pmatrix} 1 & 1 & \cdot & \cdot \end{pmatrix} \end{array}$$

When supplying either the `pattern` or the `fixed` matrices, you must ensure that the model is properly scaled. At least two standard deviations must be constant for the model to be scaled. A warning is issued if `asmprobit` detects that the model is not scaled.

The order of the elements of the `pattern` or `fixed` matrices must be the same as the numeric order of the alternative levels.

▷ Example 2

In example 1, we used the differenced covariance parameterization, the default. We now use the `structural` option to view the $J-2$ standard deviation estimates and the $(J-1)(J-2)/2$ correlation estimates. Here we will fix the standard deviations for the `air` and `train` alternatives to 1 and the correlations between `air` and the rest of the alternatives to 0.

```
(mode=air is the alternative normalizing location)
(mode=train is the alternative normalizing scale)
```

When comparing this output to that of example 1, we see that we have achieved the same log likelihood. That is, the structural parameterization using `air` as the base alternative and `train` as the scale alternative applied no restrictions on the model. This will not always be the case. We leave it up to you to try different base and scale alternatives, and you will see that not all the different combinations will achieve the same log likelihood. This is not true for the differenced covariance parameterization: it will always achieve the same log likelihood (and the maximum possible likelihood) regardless of the base and scale alternatives. This is why it is the default parameterization.

For an exercise, we can compute the differenced covariance displayed in example 1 by using the following ado-code.

```
. estat covariance
```

	air	train	bus	car
air	1			
train	0	1		
bus	0	.6001436	.6129416	
car	0	.3747012	.399619	.5158776

```
. return list
matrices:
               r(cov) :  4 x 4
. matrix cov = r(cov)
. matrix M = (1,-1,0,0 \ 1,0,-1,0 \ 1,0,0,-1)
. matrix cov1 = M*cov*M'
. matrix list cov1
symmetric cov1[3,3]
           r1         r2         r3
r1          2
r2  1.6001436  1.6129416
r3  1.3747012   1.399619  1.5158776
```

The slight difference in the regression coefficients between the example 1 and example 2 coefficient tables reflects the accuracy of the [M-5] **ghk( )** algorithm using 200 points from the Hammersley sequence.

We now fit the model using the exchangeable correlation matrix and compare the models with a likelihood-ratio test.

```
(mode=air is the alternative normalizing location)
(mode=train is the alternative normalizing scale)
. lrtest full .
Likelihood-ratio test                                 LR chi2(2)  =      0.75
(Assumption: . nested in full)                        Prob > chi2 =    0.6882
```

The likelihood-ratio test suggests that a common correlation is a plausible hypothesis, but this could be an artifact of the small sample size. The labeling of the standard deviation and correlation estimates has changed from `/lnsigma` and `/atanhr`, in the previous example, to `/lnsigmaP` and `/atanhrP`. The "P" identifies the parameter's index in the pattern matrices used by `asmprobit`. The pattern matrices are saved in `e(stdpattern)` and `e(corpattern)`. ◁

❑ Technical note

Another way to fit the model with the exchangeable correlation structure in example 2 is to use the `constraint` command to define the constraints on the `rho` parameters manually and then apply those.

```
. constraint 1 [atanhr3_2]_cons = [atanhr4_2]_cons
. constraint 2 [atanhr3_2]_cons = [atanhr4_3]_cons
. asmprobit choice travelcost termtime, case(id) alternatives(mode)
> casevars(income) constraints(1 2) structural
```

With this method, however, we must keep track of what parameterization of the `rho`s is used in estimation, and that depends on the options specified.

❑

▷ Example 3

In the last example, we used the `correlation(exchangeable)` option, reducing the number of correlation parameters from three to one. We can explore a two–correlation parameter model by specifying a `pattern` matrix in the `correlation()` option. Suppose that we wish to have the correlation between train and bus be equal to the correlation between bus and car and to have the standard deviations for the bus and car equations be equal. We will use air as the base category and train as the scale category.

(mode=air is the alternative normalizing location)
(mode=train is the alternative normalizing scale)

In the call to `asmprobit`, we did not need to specify the `basealternative()` and `scalealternative()` options because they are implied by the specifications of the pattern matrices.

◁

❑ Technical note

If you experience convergence problems, try specifying `nopivot`, increasing `intpoints()`, specifying `antithetics`, specifying `technique(nr)` with `difficult`, or specifying a switching algorithm in the `technique()` option. As a last resort, you can use the `nrtolerance()` and `showtolerance` options. Changing the base and scale alternative in the model specification can also affect convergence if the `structural` option is used.

Because simulation methods are used to obtain multivariate normal probabilities, the estimates obtained have a limited degree of precision. Moreover, the solutions are particularly sensitive to the starting values used. Experimenting with different starting values may help in obtaining convergence, and doing so is a good way to verify previous results.

If you wish to use the BHHH algorithm along with another maximization algorithm, you must specify the `initbhhh(#)` option, where # is the number of BHHH iterations to use before switching to the algorithm specified in `technique()`. The BHHH algorithm uses an outer-product-of-gradients

approximation for the Hessian, and asmprobit must perform the gradient calculations differently than for the other algorithms.

❑

❑ Technical note

If there are no alternative-specific variables in your model, the variance–covariance matrix parameters are not identifiable. For such a model to converge, you would therefore need to use correlation(independent) and stddev(homoskedastic). A better alternative is to use mprobit, which is geared specifically toward models with only case-specific variables. See [R] **mprobit**.

❑

Saved results

asmprobit saves the following in e():

Scalars

e(N)	number of observations
e(N_case)	number of cases
e(k)	number of parameters
e(k_alt)	number of alternatives
e(k_indvars)	number of alternative-specific variables
e(k_casevars)	number of case-specific variables
e(k_sigma)	number of variance estimates
e(k_rho)	number of correlation estimates
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(df_m)	model degrees of freedom
e(ll)	log simulated-likelihood
e(N_clust)	number of clusters
e(const)	constant indicator
e(i_base)	base alternative index
e(i_scale)	scale alternative index
e(mc_points)	number of Monte Carlo replications
e(mc_burn)	starting sequence index
e(mc_antithetics)	antithetics indicator
e(chi2)	χ^2
e(p)	significance
e(fullcov)	unstructured covariance indicator
e(structcov)	1 if structured covariance; 0 otherwise
e(cholesky)	Cholesky-factored covariance indicator
e(alt_min)	minimum number of alternatives
e(alt_avg)	average number of alternatives
e(alt_max)	maximum number of alternatives
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	asmprobit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(indvars)	alternative-specific independent variable
e(casevars)	case-specific variables
e(case)	variable defining cases
e(altvar)	variable defining alternatives
e(alteqs)	alternative equation names
e(alt#)	alternative labels
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(correlation)	correlation structure
e(stddev)	variance structure
e(cov_class)	class of the covariance structure
e(chi2type)	Wald, type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(mc_method)	technique used to generate sequences
e(mc_seed)	random-number generator seed
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(datasignature)	the checksum
e(datasignaturevars)	variables used in calculation of checksum
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(mfx_dlg)	program used to implement estat mfx dialog
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(stats)	alternative statistics
e(stdpattern)	variance pattern
e(stdfixed)	fixed and free standard deviations
e(altvals)	alternative values
e(altfreq)	alternative frequencies
e(alt_casevars)	indicators for estimated case-specific coefficients—e(k_alt)×e(k_casevars)
e(corpattern)	correlation structure
e(corfixed)	fixed and free correlations
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

asmprobit is implemented as an ado-file.

The simulated maximum likelihood estimates for the MNP are obtained using ml; see [R] **ml**. The likelihood evaluator implements the GHK algorithm to approximate the multivariate distribution function (Geweke 1989; Hajivassiliou and McFadden 1998; Keane and Wolpin 1994). The technique

is also described in detail by Genz (1992), but Genz describes a more general algorithm where both lower and upper bounds of integration are finite. We briefly describe the GHK simulator and refer you to Bolduc (1999) for the score computations.

As discussed earlier, the latent variables for a J-alternative model are $\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$, for $j = 1, \ldots, J$, $i = 1, \ldots, n$, and $\boldsymbol{\xi}_i' = (\xi_{i,1}, \ldots, \xi_{i,\mathrm{J}}) \sim \mathrm{MVN}(\mathbf{0}, \boldsymbol{\Omega})$. The experimenter observes alternative k for the ith observation if $k = \arg\max(\eta_{ij}, j = 1, \ldots, J)$. Let

$$\begin{aligned} v_{ij'} &= \eta_{ij} - \eta_{ik} \\ &= (\mathbf{x}_{ij} - \mathbf{x}_{ik})\boldsymbol{\beta} + \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \boldsymbol{\delta}_{ij'}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned}$$

where $j' = j$ if $j < k$ and $j' = j - 1$ if $j > k$, so that $j' = 1, \ldots, J-1$. Further, $\epsilon_i = (\epsilon_{i1}, \ldots, \epsilon_{i,\mathrm{J}-1}) \sim \mathrm{MVN}(\mathbf{0}, \boldsymbol{\Sigma}_{(k)})$. $\boldsymbol{\Sigma}$ is indexed by k because it depends on the choice made. We denote the deterministic part of the model as $\lambda_{ij'} = \boldsymbol{\delta}_{ij'}\boldsymbol{\beta} + \mathbf{z}_j\boldsymbol{\gamma}_{j'}$, and the probability of this event is

$$\begin{aligned} \Pr(y_i = k) &= \Pr(v_{i1} \le 0, \ldots, v_{i,J-1} \le 0) \\ &= \Pr(\epsilon_{i1} \le -\lambda_{i1}, \ldots, \epsilon_{i,J-1} \le -\lambda_{i,J-1}) \\ &= (2\pi)^{-(J-1)/2} \, |\boldsymbol{\Sigma}_{(k)}|^{-1/2} \int_{-\infty}^{-\lambda_{i1}} \cdots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\tfrac{1}{2}\mathbf{z}'\boldsymbol{\Sigma}_{(k)}^{-1}\mathbf{z}\right) d\mathbf{z} \end{aligned} \tag{3}$$

Simulated likelihood

For clarity in the discussion that follows, we drop the index denoting case so that for an arbitrary observation $v' = (v_1, \ldots, v_{J-1})$, $\boldsymbol{\lambda}' = (\lambda_1, \ldots, \lambda_{J-1})$, and $\boldsymbol{\epsilon}' = (\epsilon_1, \ldots, \epsilon_{J-1})$.

The Cholesky-factored variance–covariance, $\boldsymbol{\Sigma} = \mathbf{L}\mathbf{L}'$, is lower triangular,

$$\mathbf{L} = \begin{pmatrix} l_{11} & 0 & \ldots & 0 \\ l_{21} & l_{22} & \ldots & 0 \\ \vdots & \vdots & & \vdots \\ l_{J-1,1} & l_{J-1,2} & \ldots & l_{J-1,J-1} \end{pmatrix}$$

and the correlated latent-variable errors can be expressed as linear functions of uncorrelated normal variates, $\epsilon = \mathbf{L}\zeta$, where $\zeta' = (\zeta_1, \ldots, \zeta_{J-1})$ and $\zeta_j \sim$ iid $\mathrm{N}(0, 1)$. We now have $v = \lambda + \mathbf{L}\zeta$, and by defining

$$z_j = \begin{cases} -\dfrac{\lambda_1}{l_{11}} & \text{for } j = 1 \\ -\dfrac{\lambda_j + \sum_{i=1}^{j-1} l_{ji}\zeta_i}{l_{jj}} & \text{for } j = 2, \ldots, J-1 \end{cases} \tag{4}$$

we can express the probability statement (3) as the product of conditional probabilities

$$\begin{aligned} \Pr(y_i = k) = \Pr(\zeta_1 \le z_1) \, &\Pr(\zeta_2 \le z_2 \mid \zeta_1 \le z_1) \cdots \\ &\Pr(\zeta_{J-1} \le z_{J-1} \mid \zeta_1 \le z_1, \ldots, \zeta_{J-2} \le z_{J-2}) \end{aligned}$$

because

$$\begin{aligned}\Pr(v_1 \le 0) &= \Pr(\lambda_1 + l_{11}\zeta_1 \le 0)\\ &= \Pr\left(\zeta_1 \le -\frac{\lambda_1}{l_{11}}\right)\\ \Pr(v_2 \le 0) &= \Pr(\lambda_2 + l_{21}\zeta_1 + l_{22}\zeta_2 \le 0)\\ &= \Pr\left(\zeta_2 \le -\frac{\lambda_2 + l_{21}\zeta_1}{l_{22}} \mid \zeta_1 \le -\frac{\lambda_1}{l_{11}}\right)\\ &\ldots\end{aligned}$$

The Monte Carlo algorithm then must make draws from the truncated standard normal distribution. It does so by generating $J-1$ uniform variates, $\delta_j, j = 1, \ldots, J-1$, and computing

$$\widetilde{\zeta}_j = \begin{cases} \Phi^{-1}\left\{\delta_1 \Phi\left(-\dfrac{\lambda_1}{l_{11}}\right)\right\} & \text{for } j = 1\\ \Phi^{-1}\left\{\delta_j \Phi\left(\dfrac{-\lambda_j - \sum_{i=1}^{j-1} l_{ji}\widetilde{\zeta}_i}{l_{jj}}\right)\right\} & \text{for } j = 2, \ldots, J-1 \end{cases}$$

Define $\widetilde{z}_j$ by replacing $\widetilde{\zeta}_i$ for ζ_i in (4) so that the simulated probability for the lth draw is

$$p_l = \prod_{j=1}^{J-1} \Phi(\widetilde{z}_j)$$

To increase accuracy, the bounds of integration, λ_j, are ordered so that the largest integration intervals are on the inside. The rows and columns of the variance–covariance matrix are pivoted accordingly (Genz 1992).

For a more detailed description of the GHK algorithm in Stata, see Gates (2006).

Repeated draws are made, say, N, and the simulated likelihood for the ith case, denoted $\widehat{L}_i$, is computed as

$$\widehat{L}_i = \frac{1}{N}\sum_{l=1}^{N} p_l$$

The overall simulated log likelihood is $\sum_i \log \widehat{L}_i$.

If the true likelihood is L_i, the error bound on the approximation can be expressed as

$$|\widehat{L}_i - L_i| \le V(L_i) D_N\{(\delta_i)\}$$

where $V(L_i)$ is the total variation of L_i and D_N is the discrepancy, or nonuniformity, of the set of abscissas. For the uniform pseudorandom sequence, δ_i, the discrepancy is of order $O\{(\log\log N/N)^{1/2}\}$. The order of discrepancy can be improved by using quasirandom sequences.

Quasi–Monte Carlo integration is carried out by `asmprobit` by replacing the uniform deviates with either the Halton or the Hammersley sequences. These sequences spread the points more evenly than the uniform random sequence and have a smaller order of discrepancy, $O\left[\{(\log N)^{J-1}\}/N\right]$ and $O\left[\{(\log N)^{J-2}\}/N\right]$, respectively. The Halton sequence of dimension $J-1$ is generated from the first $J-1$ primes, p_k, so that on draw l we have $\mathbf{h}_l = \{r_{p_1}(l), r_{p_2}(l), \ldots, r_{p_{J-1}}(l)\}$, where

$$r_{p_k}(l) = \sum_{j=0}^{q} b_{jk}(l) p_k^{-j-1} \in (0,1)$$

is the radical inverse function of l with base p_k so that $\sum_{j=0}^{q} b_{jk}(l) p_k^j = l$, where $p_k^q \leq l < p_k^{q+1}$ (Fang and Wang 1994).

This function is demonstrated with base $p_3 = 5$ and $l = 33$, which generates $r_5(33)$. Here $q = 2$, $b_{0,3}(33) = 3$, $b_{1,5}(33) = 1$, and $b_{2,5}(33) = 1$, so that $r_5(33) = 3/5 + 1/25 + 1/625$.

The Hammersley sequence uses an evenly spaced set of points with the first $J - 2$ components of the Halton sequence

$$\mathbf{h}_l = \left\{ \frac{2l-1}{2N}, r_{p_1}(l), r_{p_2}(l), \ldots, r_{p_{J-2}}(l) \right\}$$

for $l = 1, \ldots, N$.

For a more detailed description of the Halton and Hammersley sequences, see Drukker and Gates (2006).

Computations for the derivatives of the simulated likelihood are taken from Bolduc (1999). Bolduc gives the analytical first-order derivatives for the log of the simulated likelihood with respect to the regression coefficients and the parameters of the Cholesky-factored variance–covariance matrix. `asmprobit` uses these analytical first-order derivatives and numerical second-order derivatives.

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using `vce(robust)` and `vce(cluster` *clustvar*`)`. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. Specifying `vce(robust)` is equivalent to specifying `vce(cluster` *casevar*`)`, where *casevar* is the variable that identifies the cases.

Title

asmprobit postestimation — Postestimation tools for asmprobit

Description

The following postestimation commands are of special interest after `asmprobit`:

Command	Description
`estat alternatives`	alternative summary statistics
`estat covariance`	covariance matrix of the latent-variable errors for the alternatives
`estat correlation`	correlation matrix of the latent-variable errors for the alternatives
`estat facweights`	covariance factor weights matrix
`estat mfx`	marginal effects

For information about these commands, see below.

The following standard postestimation commands are also available:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predicted probabilities, estimated linear predictor and its standard error
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation commands

`estat alternatives` displays summary statistics about the alternatives in the estimation sample and provides a mapping between the index numbers that label the covariance parameters of the model and their associated values and labels for the alternative variable.

`estat covariance` computes the estimated variance–covariance matrix of the latent-variable errors for the alternatives. The estimates are displayed, and the variance–covariance matrix is stored in `r(cov)`.

`estat correlation` computes the estimated correlation matrix of the latent-variable errors for the alternatives. The estimates are displayed, and the correlation matrix is stored in `r(cor)`.

`estat facweights` displays the covariance factor weights matrix and stores it in `r(C)`.

`estat mfx` computes the simulated probability marginal effects.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic altwise]
predict [type] {stub*|newvarlist} [if] [in], scores
```

statistic	Description
Main	
`pr`	probability alternative is chosen; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability that alternative j is chosen in case i.

`xb` calculates the linear prediction $\mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j$ for alternative j and case i.

`stdp` calculates the standard error of the linear predictor.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The `xb` and `stdp` options always use alternativewise deletion.

`scores` calculates the scores for each coefficient in `e(b)`. This option requires a new variable list of length equal to the number of columns in `e(b)`. Otherwise, use the *stub*`*` option to have `predict` generate enumerated variables with prefix *stub*.

Syntax for estat alternatives

```
estat alternatives
```

Menu

Statistics > Postestimation > Reports and statistics

Syntax for estat covariance

```
estat covariance [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat covariance

`format(%fmt)` sets the matrix display format. The default is `format(%9.0g)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat correlation

```
estat correlation [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat correlation

`format(%fmt)` sets the matrix display format. The default is `format(%9.4f)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat facweights

```
estat facweights [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat facweights

`format(%fmt)` sets the matrix display format. The default is `format(%9.0f)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat mfx

```
estat mfx [if] [in] [, options]
```

options	Description
Main	
varlist(*varlist*)	display marginal effects for *varlist*
at(mean [*atlist*] | median [*atlist*])	calculate marginal effects at these values
Options	
level(#)	set confidence interval level; default is level(95)
nodiscrete	treat indicator variables as continuous
noesample	do not restrict calculation of means and medians to the estimation sample
nowght	ignore weights when calculating means and medians

Menu

Statistics > Postestimation > Reports and statistics

Options for estat mfx

Main

varlist(*varlist*) specifies the variables for which to display marginal effects. The default is all variables.

at(mean [*atlist*] | median [*atlist*]) specifies the values at which the marginal effects are to be calculated. *atlist* is

[[*alternative*:*variable* = #] [*variable* = #] [...]]

The default is to calculate the marginal effects at the means of the independent variables at the estimation sample, at(mean).

After specifying the summary statistic, you can specify a series of specific values for variables. You can specify values for alternative-specific variables by alternative, or you can specify one value for all alternatives. You can specify only one value for case-specific variables. For example, in the travel dataset, income is a case-specific variable, whereas termtime and travelcost are alternative-specific variables. The following would be a legal syntax for estat mfx:

```
. estat mfx, at(mean air:termtime=50 travelcost=100 income=60)
```

When nodiscrete is not specified, at(mean [*atlist*]) or at(median [*atlist*]) has no effect on computing marginal effects for indicator variables, which are calculated as the discrete change in the simulated probability as the indicator variable changes from 0 to 1.

The mean and median computations respect any if and in qualifiers, so you can restrict the data over which the means or medians are computed. You can even restrict the values to a specific case; for example,

```
. estat mfx if case==21
```

Options

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] **20.7 Specifying the width of confidence intervals**.

`nodiscrete` specifies that indicator variables be treated as continuous variables. An indicator variable is one that takes on the value 0 or 1 in the estimation sample. By default, the discrete change in the simulated probability is computed as the indicator variable changes from 0 to 1.

`noesample` specifies that the whole dataset be considered instead of only those marked in the `e(sample)` defined by the `asmprobit` command.

`nowght` specifies that weights be ignored when calculating the means or medians.

Remarks

Remarks are presented under the following headings:

Predicted probabilities
Obtaining estimation statistics
Obtaining marginal effects

Predicted probabilities

After fitting an alternative-specific multinomial probit model, you can use `predict` to obtain the simulated probabilities that an individual will choose each of the alternatives. When evaluating the multivariate normal probabilities via Monte Carlo simulation, `predict` uses the same method to generate the random sequence of numbers as the previous call to `asmprobit`. For example, if you specified `intmethod(Halton)` when fitting the model, `predict` also uses the Halton sequence.

▷ Example 1

In example 1 of [R] **asmprobit**, we fit a model of individuals' travel-mode choices. We can obtain the simulated probabilities that an individual chooses each alternative by using `predict`:

```
. use http://www.stata-press.com/data/r12/travel
. asmprobit choice travelcost termtime, case(id) alternatives(mode)
> casevars(income)
  (output omitted)
. predict prob
(option pr assumed; Pr(mode))
. list id mode prob choice in 1/12, sepby(id)
```

	id	mode	prob	choice
1.	1	air	.1494137	0
2.	1	train	.329167	0
3.	1	bus	.1320298	0
4.	1	car	.3898562	1
5.	2	air	.2565875	0
6.	2	train	.2761054	0
7.	2	bus	.0116135	0
8.	2	car	.4556921	1
9.	3	air	.2098406	0
10.	3	train	.1081824	0
11.	3	bus	.1671841	0
12.	3	car	.5147822	1

◁

Obtaining estimation statistics

Once you have fit a multinomial probit model, you can obtain the estimated variance or correlation matrices for the model alternatives by using the `estat` command.

▷ Example 2

To display the correlations of the errors in the latent-variable equations, we type

```
. estat correlation
```

	train	bus	car
train	1.0000		
bus	0.8909	1.0000	
car	0.7895	0.8951	1.0000

```
Note: correlations are for alternatives differenced with air
```

The covariance matrix can be displayed by typing

```
. estat covariance
```

	train	bus	car
train	2		
bus	1.600208	1.613068	
car	1.37471	1.399703	1.515884

```
Note: covariances are for alternatives differenced with air
```

◁

Obtaining marginal effects

The marginal effects are computed as the derivative of the simulated probability for an alternative with respect to an independent variable. A table of marginal effects is displayed for each alternative, with the table containing the marginal effect for each case-specific variable and the alternative for each alternative-specific variable.

By default, the marginal effects are computed at the means of each continuous independent variable over the estimation sample. For indicator variables, the difference in the simulated probability evaluated at 0 and 1 is computed by default. Indicator variables will be treated as continuous variables if the `nodiscrete` option is used.

▷ Example 3

Continuing with our model from example 1, we obtain the marginal effects for alternatives `air`, `train`, `bus`, and `car` evaluated at the mean values of each independent variable. Recall that the `travelcost` and `termtime` variables are alternative specific, taking on different values for each alternative, so they have a separate marginal effect for each alternative.

```
. estat mfx
```

Pr(choice = air) = .29434926

variable	dp/dx	Std. Err.	z	P>|z|	[95% C.I.]		X
travelcost

First, we note that there is a separate marginal effects table for each alternative and that table begins by reporting the overall probability of choosing the alternative, for example, 0.2944 for air travel. We see in the first table that a unit increase in terminal time for air travel from 61.01 minutes will result in a decrease in probability of choosing air travel (when the probability is evaluated at the mean of all variables) by approximately 0.01, with a 95% confidence interval of about -0.016 to -0.005. Travel cost has a less negative effect of choosing air travel (at the average cost of 102.65). Alternatively, an increase in terminal time and travel cost for train, bus, or car from these mean values will increase the chance for air travel to be chosen. Also, with an increase in income from 34.5, it would appear that an individual would be more likely to choose air or automobile travel over bus or train. (While the marginal effect for bus travel is positive, it is not significant.)

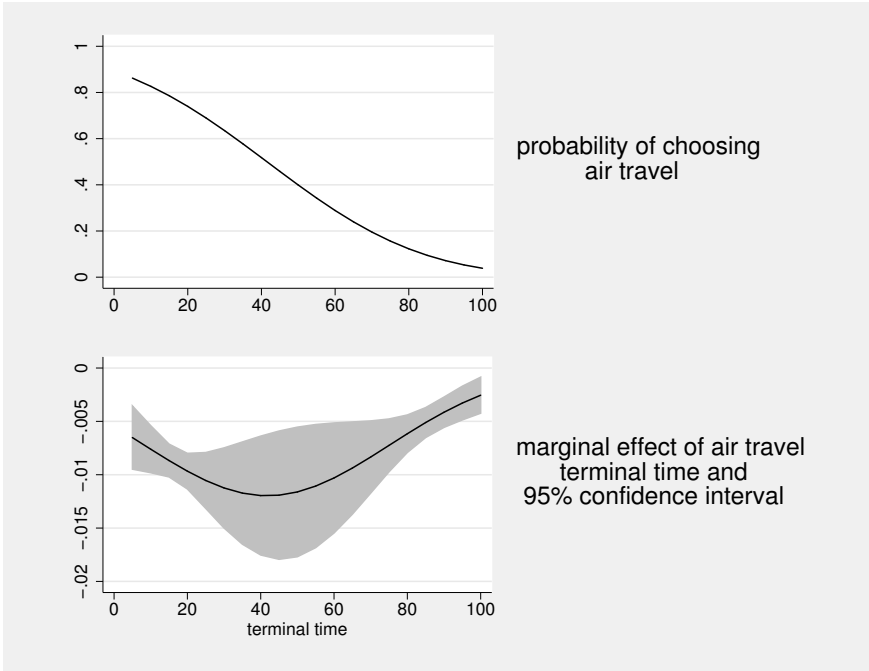
◁

▷ Example 4

Plotting the simulated probability marginal effect evaluated over a range of values for an independent variable may be more revealing than a table of values. Below are the commands for generating the simulated probability marginal effect of air travel for increasing air travel terminal time. We fix all other independent variables at their medians.

```
. qui gen meff = .
. qui gen tt = .
. qui gen lb = .
. qui gen ub = .
. forvalues i=0/19 {
  2.         local termtime = 5+5*`i'
  3.         qui replace tt = `termtime' if _n == `i'+1
  4.         qui estat mfx, at(median air:termtime=`termtime') var(termtime)
  5.         mat air = r(air)
  6.         qui replace meff = air[1,1] if _n == `i'+1
  7.         qui replace lb = air[1,5] if _n == `i'+1
  8.         qui replace ub = air[1,6] if _n == `i'+1
  9.         qui replace prob = r(pr_air) if _n == `i'+1
 10. }
. label variable tt "terminal time"
```

```
. twoway (rarea lb ub tt, pstyle(ci)) (line meff tt, lpattern(solid)), name(meff)
> legend(off) title("  marginal effect of air travel" "terminal time and"
> "95% confidence interval", position(3))
. twoway line prob tt, name(prob) title("  probability of choosing" "air travel",
> position(3)) graphregion(margin(r+9)) ytitle("") xtitle("")
. graph combine prob meff, cols(1) graphregion(margin(l+5 r+5))
```



From the graphs, we see that the simulated probability of choosing air travel decreases in an sigmoid fashion. The marginal effects display the rate of change in the simulated probability as a function of the air travel terminal time. The rate of change in the probability of choosing air travel decreases until the air travel terminal time reaches about 45; thereafter, it increases.

◁

Saved results

`estat mfx` saves the following in `r()`:

Scalars

`r(pr_`*alt*`)` scalars containing the computed probability of each alternative evaluated at the value that is labeled X in the table output. Here *alt* are the labels in the macro `e(alteqs)`.

Matrices

`r(`*alt*`)` matrices containing the computed marginal effects and associated statistics. There is one matrix for each alternative, where *alt* are the labels in the macro `e(alteqs)`. Column 1 of each matrix contains the marginal effects; column 2, their standard errors; columns 3 and 4, their z statistics and the p-values for the z statistics; and columns 5 and 6, the confidence intervals. Column 7 contains the values of the independent variables used to compute the probabilities `r(pr_`*alt*`)`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Marginal effects

The marginal effects are computed as the derivative of the simulated probability with respect to each independent variable. A set of marginal effects is computed for each alternative; thus, for J alternatives, there will be J tables. Moreover, the alternative-specific variables will have J entries, one for each alternative in each table. The details of computing the effects are different for alternative-specific variables and case-specific variables, as well as for continuous and indicator variables.

We use the latent-variable notation of `asmprobit` (see [R] **asmprobit**) for a J-alternative model and, for notational convenience, we will drop any subscripts involving observations. We then have the following linear functions $\eta_j = \mathbf{x}_j\boldsymbol{\beta} + \mathbf{z}\boldsymbol{\alpha}_j$, for $j = 1, \ldots, J$. Let k index the alternative of interest, and then

$$\begin{aligned} v_{j'} &= \eta_j - \eta_k \\ &= (\mathbf{x}_j - \mathbf{x}_k)\boldsymbol{\beta} + \mathbf{z}(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \boldsymbol{\epsilon}_{j'} \end{aligned}$$

where $j' = j$ if $j < k$ and $j' = j - 1$ if $j > k$, so that $j' = 1, \ldots, J-1$ and $\boldsymbol{\epsilon}_{j'} \sim \text{MVN}(\mathbf{0}, \boldsymbol{\Sigma})$. Denote $p_k = \Pr(v_1 \leq 0, \ldots, v_{J-1} \leq 0)$ as the simulated probability of choosing alternative k given profile $\mathbf{x}_k$ and $\mathbf{z}$. The marginal effects are then $\partial p_k/\partial \mathbf{x}_k$, $\partial p_k/\partial \mathbf{x}_j$, and $\partial p_k/\partial \mathbf{z}$, where $k = 1, \ldots, J$, $j \neq k$. `asmprobit` analytically computes the first-order derivatives of the simulated probability with respect to the v's, and the marginal effects for $\mathbf{x}$'s and $\mathbf{z}$ are obtained via the chain rule. The standard errors for the marginal effects are computed using the delta method.

Title

asroprobit — Alternative-specific rank-ordered probit regression

Syntax

```
asroprobit depvar [indepvars] [if] [in] [weight], case(varname)
    alternatives(varname) [options]
```

options	Description
Model	
* `case(`*varname*`)`	use *varname* to identify cases
* `alternatives(`*varname*`)`	use *varname* to identify the alternatives available for each case
`casevars(`*varlist*`)`	case-specific variables
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
Model 2	
`correlation(`*correlation*`)`	correlation structure of the latent-variable errors
`stddev(`*stddev*`)`	variance structure of the latent-variable errors
`structural`	use the structural covariance parameterization; default is the differenced covariance parameterization
`factor(#)`	use the factor covariance structure with dimension #
`noconstant`	suppress the alternative-specific constant terms
`basealternative(`*# | lbl | str*`)`	alternative used for normalizing location
`scalealternative(`*# | lbl | str*`)`	alternative used for normalizing scale
`altwise`	use alternativewise deletion instead of casewise deletion
`reverse`	interpret the lowest rank in *depvar* as the best; the default is the highest rank is the best
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`notransform`	do not transform variance–covariance estimates to the standard deviation and correlation metric
`nocnsreport`	do not display constraints
display_options	control column formats and line width

Integration

intmethod(*seqtype*)	type of quasi- or pseudouniform sequence
intpoints(#)	number of points in each sequence
intburn(#)	starting index in the Hammersley or Halton sequence
intseed(*code* | #)	pseudouniform random-number seed
antithetics	use antithetic draws
nopivot	do not use integration interval pivoting
initbhhh(#)	use the BHHH optimization algorithm for the first # iterations
favor(speed | space)	favor speed or space when generating integration points

Maximization

maximize_options	control the maximization process
coeflegend	display legend instead of statistics

correlation	Description
unstructured	one correlation parameter for each pair of alternatives; correlations with the basealternative() are zero; the default
exchangeable	one correlation parameter common to all pairs of alternatives; correlations with the basealternative() are zero
independent	constrain all correlation parameters to zero
pattern *matname*	user-specified matrix identifying the correlation pattern
fixed *matname*	user-specified matrix identifying the fixed and free correlation parameters

stddev	Description
heteroskedastic	estimate standard deviation for each alternative; standard deviations for basealternative() and scalealternative() set to one
homoskedastic	all standard deviations are one
pattern *matname*	user-specified matrix identifying the standard deviation pattern
fixed *matname*	user-specified matrix identifying the fixed and free standard deviations

seqtype	Description
hammersley	Hammersley point set
halton	Halton point set
random	uniform pseudorandom point set

*case(*varname*) and alternatives(*varname*) are required.
bootstrap, by, jackknife, statsby, and xi are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Statistics > Ordinal outcomes > Rank-ordered probit regression

Description

`asroprobit` fits rank-ordered probit (ROP) models by using maximum simulated likelihood (MSL). The model allows you to relax the independence of irrelevant alternatives (IIA) property that is characteristic of the rank-ordered logistic model by estimating the variance–covariance parameters of the latent-variable errors. Each unique identifier in the `case()` variable has multiple alternatives identified in the `alternatives()` variable, and *depvar* contains the ranked alternatives made by each case. Only the order in the ranks, not the magnitude of their differences, is assumed to be relevant. By default, the largest rank indicates the more desirable alternative. Use the `reverse` option if the lowest rank should be interpreted as the more desirable alternative. Tied ranks are allowed, but they increase the computation time because all permutations of the tied ranks are used in computing the likelihood for each case. `asroprobit` allows two types of independent variables: alternative-specific variables, in which the values of each variable vary with each alternative, and case-specific variables, which vary with each case.

The estimation technique of `asroprobit` is nearly identical to that of `asmprobit`, and the two routines share many of the same options; see [R] **asmprobit**.

Options

Model

`case(`*varname*`)` specifies the variable that identifies each case. This variable identifies the individuals or entities making a choice. `case()` is required.

`alternatives(`*varname*`)` specifies the variable that identifies the alternatives available for each case. The number of alternatives can vary with each case; the maximum number of alternatives is 20. `alternatives()` is required.

`casevars(`*varlist*`)` specifies the case-specific variables that are constant for each `case()`. If there are a maximum of J alternatives, there will be $J-1$ sets of coefficients associated with `casevars()`.

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

Model 2

`correlation(`*correlation*`)` specifies the correlation structure of the latent-variable errors.

`correlation(unstructured)` is the most general and has $J(J-3)/2+1$ unique correlation parameters. This is the default unless `stddev()` or `structural` are specified.

`correlation(exchangeable)` provides for one correlation coefficient common to all latent variables, except the latent variable associated with the `basealternative()`.

`correlation(independent)` assumes that all correlations are zero.

`correlation(pattern` *matname*`)` and `correlation(fixed` *matname*`)` give you more flexibility in defining the correlation structure. See *Variance structures* in [R] **asmprobit** for more information.

`stddev(`*stddev*`)` specifies the variance structure of the latent-variable errors.

`stddev(heteroskedastic)` is the most general and has $J-2$ estimable parameters. The standard deviations of the latent-variable errors for the alternatives specified in `basealternative()` and `scalealternative()` are fixed to one.

`stddev(homoskedastic)` constrains all the standard deviations to equal one.

`stddev(pattern` *matname*`)` and `stddev(fixed` *matname*`)` give you added flexibility in defining the standard deviation parameters. See *Variance structures* in [R] **asmprobit** for more information.

`structural` requests the $J \times J$ structural covariance parameterization instead of the default $J-1 \times J-1$ differenced covariance parameterization (the covariance of the latent errors differenced with that of the base alternative). The differenced covariance parameterization will achieve the same maximum simulated likelihood regardless of the choice of `basealternative()` and `scalealternative()`. On the other hand, the structural covariance parameterization imposes more normalizations that may bound the model away from its maximum likelihood and thus prevent convergence with some datasets or choices of `basealternative()` and `scalealternative()`.

`factor(#)` requests that the factor covariance structure of dimension # be used. The `factor()` option can be used with the `structural` option but cannot be used with `stddev()` or `correlation()`. A $\# \times J$ (or $\# \times J-1$) matrix, $\mathbf{C}$, is used to factor the covariance matrix as $I + \mathbf{C}'\mathbf{C}$, where I is the identity matrix of dimension J (or $J-1$). The column dimension of $\mathbf{C}$ depends on whether the covariance is structural or differenced. The row dimension of $\mathbf{C}$, #, must be less than or equal to `floor(`$(J(J-1)/2-1)/(J-2)$`)`, because there are only $J(J-1)/2-1$ identifiable variance–covariance parameters. This covariance parameterization may be useful for reducing the number of covariance parameters that need to be estimated.

If the covariance is structural, the column of $\mathbf{C}$ corresponding to the base alternative contains zeros. The column corresponding to the scale alternative has a one in the first row and zeros elsewhere. If the covariance is differenced, the column corresponding to the scale alternative (differenced with the base) has a one in the first row and zeros elsewhere.

`noconstant` suppresses the $J-1$ alternative-specific constant terms.

`basealternative(#` | *lbl* | *str*`)` specifies the alternative used to normalize the latent-variable location (also referred to as the level of utility). The base alternative may be specified as a number, label, or string. The standard deviation for the latent-variable error associated with the base alternative is fixed to one, and its correlations with all other latent-variable errors are set to zero. The default is the first alternative when sorted. If a `fixed` or `pattern` matrix is given in the `stddev()` and `correlation()` options, the `basealternative()` will be implied by the fixed standard deviations and correlations in the matrix specifications. `basealternative()` cannot be equal to `scalealternative()`.

`scalealternative(#` | *lbl* | *str*`)` specifies the alternative used to normalize the latent-variable scale (also referred to as the scale of utility). The scale alternative may be specified as a number, label, or string. The default is to use the second alternative when sorted. If a `fixed` or `pattern` matrix is given in the `stddev()` option, the `scalealternative()` will be implied by the fixed standard deviations in the matrix specification. `scalealternative()` cannot be equal to `basealternative()`.

If a `fixed` or `pattern` matrix is given for the `stddev()` option, the base alternative and scale alternative are implied by the standard deviations and correlations in the matrix specifications, and they need not be specified in the `basealternative()` and `scalealternative()` options.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion; that is, the entire group of observations making up a case is deleted if any missing values are encountered. This option does not apply to observations that are marked out by the `if` or `in` qualifier or the `by` prefix.

`reverse` directs `asroprobit` to interpret the rank in *depvar* that is smallest in value as the preferred alternative. By default, the rank that is largest in value is the favored alternative.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `basealternative()` and `scalealternative()`.

Reporting

`level(#)`; see [R] **estimation options**.

`notransform` prevents retransforming the Cholesky-factored variance–covariance estimates to the correlation and standard deviation metric.

This option has no effect if `structural` is not specified because the default differenced variance–covariance estimates have no interesting interpretation as correlations and standard deviations. `notransform` also has no effect if the `correlation()` and `stddev()` options are specified with anything other than their default values. Here it is generally not possible to factor the variance–covariance matrix, so optimization is already performed using the standard deviation and correlation representations.

`nocnsreport`; see [R] **estimation options**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Integration

`intmethod(hammersley | halton | random)` specifies the method of generating the point sets used in the quasi–Monte Carlo integration of the multivariate normal density. `intmethod(hammersley)`, the default, uses the Hammersley sequence; `intmethod(halton)` uses the Halton sequence; and `intmethod(random)` uses a sequence of uniform random numbers.

`intpoints(#)` specifies the number of points to use in the quasi–Monte Carlo integration. If this option is not specified, the number of points is $50 \times J$ if `intmethod(hammersley)` or `intmethod(halton)` is used and $100 \times J$ if `intmethod(random)` is used. Larger values of `intpoints()` provide better approximations of the log likelihood, but at the cost of added computation time.

`intburn(#)` specifies where in the Hammersley or Halton sequence to start, which helps reduce the correlation between the sequences of each dimension. The default is 0. This option may not be specified with `intmethod(random)`.

`intseed(`*code* | `#)` specifies the seed to use for generating the uniform pseudorandom sequence. This option may be specified only with `intmethod(random)`. *code* refers to a string that records the state of the random-number generator `runiform()`; see [R] **set seed**. An integer value # may be used also. The default is to use the current seed value from Stata's uniform random-number generator, which can be obtained from `c(seed)`.

`antithetics` specifies that antithetic draws be used. The antithetic draw for the $J - 1$ vector uniform-random variables, $\mathbf{x}$, is $1 - \mathbf{x}$.

`nopivot` turns off integration interval pivoting. By default, `asroprobit` will pivot the wider intervals of integration to the interior of the multivariate integration. This improves the accuracy of the quadrature estimate. However, discontinuities may result in the computation of numerical second-order derivatives using finite differencing (for the Newton–Raphson optimize technique, `tech(nr)`) when few simulation points are used, resulting in a non–positive-definite Hessian. `asroprobit`

uses the Broyden–Fletcher–Goldfarb–Shanno optimization algorithm, by default, which does not require computing the Hessian numerically using finite differencing.

`initbhhh(#)` specifies that the Berndt–Hall–Hall–Hausman (BHHH) algorithm be used for the initial # optimization steps. This option is the only way to use the BHHH algorithm along with other optimization techniques. The algorithm switching feature of `ml`'s `technique()` option cannot include `bhhh`.

`favor(speed | space)` instructs `asroprobit` to favor either speed or space when generating the integration points. `favor(speed)` is the default. When favoring speed, the integration points are generated once and stored in memory, thus increasing the speed of evaluating the likelihood. This speed increase can be seen when there are many cases or when the user specifies a large number of integration points, `intpoints(#)`. When favoring space, the integration points are generated repeatedly with each likelihood evaluation.

For unbalanced data, where the number of alternatives varies with each case, the estimates computed using `intmethod(random)` will vary slightly between `favor(speed)` and `favor(space)`. This is because the uniform sequences will not be identical, even when initiating the sequences using the same uniform seed, `intseed(`*code* | `#)`. For `favor(speed)`, `ncase` blocks of `intpoints(#)` $\times$ $J - 2$ uniform points are generated, where J is the maximum number of alternatives. For `favor(space)`, the column dimension of the matrices of points varies with the number of alternatives that each case has.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, [`no`]`log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**.

The following options may be particularly useful in obtaining convergence with `asroprobit`: `difficult`, `technique(`*algorithm_spec*`)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`.

If `technique()` contains more than one algorithm specification, `bhhh` cannot be one of them. To use the BHHH algorithm with another algorithm, use the `initbhhh()` option and specify the other algorithm in `technique()`.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

When specifying `from(`*matname* [`, copy`]`)`, the values in *matname* associated with the latent-variable error variances must be for the log-transformed standard deviations and inverse-hyperbolic tangent-transformed correlations. This option makes using the coefficient vector from a previously fitted `asroprobit` model convenient as a starting point.

The following option is available with `asroprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

The mathematical description and numerical computations of the rank-ordered probit model are similar to that of the multinomial probit model. The only difference is that the dependent variable of the rank-ordered probit model is ordinal, showing preferences among alternatives, as opposed to the binary dependent variable of the multinomial probit model, indicating a chosen alternative. We will describe how the likelihood of a ranking is computed using the latent-variable framework here, but for details of the latent-variable parameterization of these models and the method of maximum simulated likelihood, see [R] **asmprobit**.

Consider the latent-variable parameterization of a J alternative rank-ordered probit model. Using the notation from `asmprobit`, we have variables η_{ij}, $j = 1, \ldots, J$, such that

$$\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$$

Here the $\mathbf{x}_{ij}$ are the alternative-specific independent variables, the $\mathbf{z}_i$ are the case-specific variables, and the ξ_{ij} are multivariate normal with mean zero and covariance $\boldsymbol{\Omega}$. Without loss of generality, assume that individual i ranks the alternatives in order of the alternative indices $j = 1, 2, \ldots, J$, so the alternative J is the preferred alternative and alternative 1 is the least preferred alternative. The probability of this ranking given $\boldsymbol{\beta}$ and $\boldsymbol{\alpha}_j$ is the probability that $\eta_{i,J-1} - \eta_{i,J} \leq 0$ and $\eta_{i,J-2} - \eta_{i,J-1} \leq 0$, ..., and $\eta_{i,1} - \eta_{i,2} \leq 0$.

▷ Example 1

Long and Freese (2006) provide an example of a rank-ordered logit model with alternative-specific variables. We use this dataset to demonstrate `asroprobit`. The data come from the Wisconsin Longitudinal Study. This is a study of 1957 Wisconsin high school graduates that were asked to rate their relative preference of four job characteristics: esteem, a job other people regard highly; variety, a job that is not repetitive and allows you to do a variety of things; autonomy, a job where your supervisor does not check on you frequently; and security, a job with a low risk of being laid off. The case-specific covariates are gender, `female`, an indicator variable for females, and `score`, a score on a general mental ability test measured in standard deviations. The alternative-specific variables are `high` and `low`, which indicate whether the respondent's current job is high or low in esteem, variety, autonomy, or security. This approach provides three states for a respondent's current job status for each alternative, $(1, 0)$, $(0, 1)$, and $(0, 0)$, using the notation (`high`, `low`). The score $(1, 1)$ is omitted because the respondent's current job cannot be considered both high and low in one of the job characteristics. The $(0, 0)$ score would indicate that the respondent's current job does not rank high or low (is neutral) in a job characteristic. The alternatives are ranked such that 1 is the preferred alternative and 4 is the least preferred.

```
. use http://www.stata-press.com/data/r12/wlsrank
(1992 Wisconsin Longitudinal Study data on job values)
. list id jobchar rank female score high low in 1/12, sepby(id)
```

	id	jobchar	rank	female	score	high	low
1.	1	security	1	1	.0492111	0	0
2.	1	autonomy	4	1	.0492111	0	0
3.	1	variety	1	1	.0492111	0	0
4.	1	esteem	3	1	.0492111	0	0
5.	5	security	2	1	2.115012	1	0
6.	5	variety	2	1	2.115012	1	0
7.	5	esteem	2	1	2.115012	1	0
8.	5	autonomy	1	1	2.115012	0	0
9.	7	autonomy	1	0	1.701852	1	0
10.	7	variety	1	0	1.701852	0	1
11.	7	esteem	4	0	1.701852	0	0
12.	7	security	1	0	1.701852	0	0

The three cases listed have tied ranks. `asroprobit` will allow ties, but at the cost of increased computation time. To evaluate the likelihood of the first observation, `asroprobit` must compute

$$\Pr(\texttt{esteem} = 3,\ \texttt{variety} = 1,\ \texttt{autonomy} = 4,\ \texttt{security} = 2) +$$
$$\Pr(\texttt{esteem} = 3,\ \texttt{variety} = 2,\ \texttt{autonomy} = 4,\ \texttt{security} = 1)$$

and both of these probabilities are estimated using simulation. In fact, the full dataset contains 7,237 tied ranks and `asroprobit` takes a great deal of time to estimate the parameters. For exposition, we estimate the rank-ordered probit model by using the cases without ties. These cases are marked in the variable `noties`.

The model of job preference is

$$\eta_{ij} = \beta_1 \texttt{high}_{ij} + \beta_2 \texttt{low}_{ij} \; + \; \alpha_{1j}\texttt{female}_i + \alpha_{2j}\texttt{score}_i + \alpha_{0j} + \xi_{ij}$$

for $j = 1, 2, 3, 4$. The base alternative will be `esteem`, so $\alpha_{01} = \alpha_{11} = \alpha_{21} = 0$.

```
. asroprobit rank high low if noties, case(id) alternatives(jobchar)
> casevars(female score) reverse
note: variable high has 107 cases that are not alternative-specific: there is
      no within-case variability

```
(jobchar=esteem is the alternative normalizing location)
(jobchar=variety is the alternative normalizing scale)
```

We specified the `reverse` option because a rank of 1 is the highest preference. The variance–covariance estimates are for the Cholesky-factored variance–covariance for the latent-variable errors differenced with that of alternative `esteem`. We can view the estimated correlations by entering

```
. estat correlation
```

	variety	autonomy	security
variety	1.0000		
autonomy	0.4516	1.0000	
security	0.2652	0.2399	1.0000

```
Note: correlations are for alternatives differenced with esteem
```

and typing

```
. estat covariance
```

	variety	autonomy	security
variety	2		
autonomy	.8573015	1.80229	
security	.6376996	.5475882	2.890048

```
Note: covariances are for alternatives differenced with esteem
```

gives the (co)variances. [R] **mprobit** explains that if the latent-variable errors are independent, then the correlations in the differenced parameterization should be ∼0.5 and the variances should be ∼2.0, which seems to be the case here.

The coefficient estimates for the probit models can be difficult to interpret because of the normalization for location and scale. The regression estimates for the case-specific variables will be relative to the base alternative and the regression estimates for both the case-specific and alternative-specific variables are affected by the scale normalization. The more pronounced the heteroskedasticity and correlations, the more pronounced the resulting estimate differences when choosing alternatives to normalize for location and scale. However, when using the differenced covariance structure, you will obtain the same model likelihood regardless of which alternatives you choose as the base and scale alternatives. For model interpretation, you can examine the estimated probabilities and marginal effects by using postestimation routines `predict` and `estat mfx`. See [R] **asroprobit postestimation**. ◁

Saved results

asroprobit saves the following in e():

Scalars

e(N)	number of observations

Functions

e(sample)	marks estimation sample

Methods and formulas

asroprobit is implemented as an ado-file.

From a computational perspective, asroprobit is similar to asmprobit and the two programs share many numerical tools. Therefore, we will use the notation from *Methods and formulas* in [R] **asmprobit** to discuss the rank-ordered probit probability model.

The latent variables for a J-alternative model are $\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$, for $j = 1, \ldots, J$, $i = 1, \ldots, n$, and $\boldsymbol{\xi}_i' = (\xi_{i,1}, \ldots, \xi_{i,\mathrm{J}}) \sim \mathrm{MVN}(\mathbf{0}, \boldsymbol{\Omega})$. Without loss of generality, assume for the ith observation that an individual ranks the alternatives in the order of their numeric indices, $\mathbf{y}_i = (J, J-1, \ldots, 1)$, so the first alternative is the most preferred and the last alternative is the least preferred. We can then difference the latent variables such that

$$\begin{aligned} v_{ik} &= \eta_{i,k+1} - \eta_{i,k} \\ &= (\mathbf{x}_{i,k+1} - \mathbf{x}_{i,k})\boldsymbol{\beta} + \mathbf{z}_i(\boldsymbol{\alpha}_{k+1} - \boldsymbol{\alpha}_k) + \xi_{i,k+1} - \xi_{ik} \\ &= \boldsymbol{\delta}_{ik}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\gamma}_k + \epsilon_{ik} \end{aligned}$$

for $k = 1, \ldots, J-1$ and where $\epsilon_i = (\epsilon_{i1}, \ldots, \epsilon_{i,\mathrm{J}-1}) \sim \mathrm{MVN}(\mathbf{0}, \boldsymbol{\Sigma}_{(i)})$. $\boldsymbol{\Sigma}$ is indexed by i because it is specific to the ranking of individual i. We denote the deterministic part of the model as $\lambda_{ik} = \boldsymbol{\delta}_{ik}\boldsymbol{\beta} + \mathbf{z}_j\boldsymbol{\gamma}_k$, and the probability of this event is

$$\begin{aligned} \Pr(\mathbf{y}_i) &= \Pr(v_{i1} \le 0, \ldots, v_{i,J-1} \le 0) \\ &= \Pr(\epsilon_{i1} \le -\lambda_{i1}, \ldots, \epsilon_{i,J-1} \le -\lambda_{i,J-1}) \\ &= (2\pi)^{-(J-1)/2} \, |\boldsymbol{\Sigma}_{(i)}|^{-1/2} \int_{-\infty}^{-\lambda_{i1}} \cdots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\tfrac{1}{2}\mathbf{z}'\boldsymbol{\Sigma}_{(i)}^{-1}\mathbf{z}\right) d\mathbf{z} \end{aligned}$$

The integral has the same form as (3) of *Methods and formulas* in [R] **asmprobit**. See [R] **asmprobit** for details on evaluating this integral numerically by using simulation.

`asroprobit` handles tied ranks by enumeration. For k tied ranks, it will generate $k!$ rankings, where ! is the factorial operator $k! = k(k-1)(k-2)\cdots(2)(1)$. For two sets of tied ranks of size k_1 and k_2, `asroprobit` will generate $k_1!k_2!$ rankings. The total probability is the sum of the probability of each ranking. For example, if there are two tied ranks such that $\mathbf{y}_i = (J, J, J-2, \ldots, 1)$, then `asroprobit` will evaluate $\Pr(\mathbf{y}_i) = \Pr(\mathbf{y}_i^{(1)}) + \Pr(\mathbf{y}_i^{(2)})$, where $\mathbf{y}_i^{(1)} = (J, J-1, J-2, \ldots, 1)$ and $\mathbf{y}_i^{(2)} = (J-1, J, J-2, \ldots, 1)$.

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using `vce(robust)` and `vce(cluster` *clustvar*`)`. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. Specifying `vce(robust)` is equivalent to specifying `vce(cluster` *casevar*`)`, where *casevar* is the variable that identifies the cases.

Title

asroprobit postestimation — Postestimation tools for asroprobit

Description

The following postestimation commands are of special interest after `asroprobit`:

Command	Description
`estat alternatives`	alternative summary statistics
`estat covariance`	covariance matrix of the latent-variable errors for the alternatives
`estat correlation`	correlation matrix of the latent-variable errors for the alternatives
`estat facweights`	covariance factor weights matrix
`estat mfx`	marginal effects

For information about these commands, see below.

The following standard postestimation commands are also available:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predicted probabilities, estimated linear predictor and its standard error
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation commands

`estat alternatives` displays summary statistics about the alternatives in the estimation sample. The command also provides a mapping between the index numbers that label the covariance parameters of the model and their associated values and labels for the alternative variable.

`estat covariance` computes the estimated variance–covariance matrix of the latent-variable errors for the alternatives. The estimates are displayed, and the variance–covariance matrix is stored in `r(cov)`.

`estat correlation` computes the estimated correlation matrix of the latent-variable errors for the alternatives. The estimates are displayed, and the correlation matrix is stored in `r(cor)`.

`estat facweights` displays the covariance factor weights matrix and stores it in `r(C)`.

`estat mfx` computes marginal effects of a simulated probability of a set of ranked alternatives. The probability is stored in `r(pr)`, the matrix of rankings is stored in `r(ranks)`, and the matrix of marginal-effect statistics is stored in `r(mfx)`.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic altwise]

predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
pr	probability of each ranking, by case; the default
pr1	probability that each alternative is preferred
xb	linear prediction
stdp	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of each ranking. For each case, one probability is computed for the ranks in `e(depvar)`.

`pr1` calculates the probability that each alternative is preferred.

`xb` calculates the linear prediction $\mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j$ for alternative j and case i.

`stdp` calculates the standard error of the linear predictor.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The `xb` and `stdp` options always use alternativewise deletion.

`scores` calculates the scores for each coefficient in `e(b)`. This option requires a new variable list of length equal to the number of columns in `e(b)`. Otherwise, use the *stub*`*` option to have `predict` generate enumerated variables with prefix *stub*.

Syntax for estat alternatives

```
estat alternatives
```

Menu

Statistics > Postestimation > Reports and statistics

Syntax for estat covariance

```
estat covariance [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat covariance

`format(%fmt)` sets the matrix display format. The default is `format(%9.0g)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat correlation

```
estat correlation [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat correlation

`format(%fmt)` sets the matrix display format. The default is `format(%9.4f)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat facweights

```
estat facweights [ , format(%fmt) border(bspec) left(#) ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat facweights

`format(%fmt)` sets the matrix display format. The default is `format(%9.0f)`.

`border(bspec)` sets the matrix display border style. The default is `border(all)`. See [P] **matlist**.

`left(#)` sets the matrix display left indent. The default is `left(2)`. See [P] **matlist**.

Syntax for estat mfx

```
estat mfx [if] [in] [, options]
```

options	Description
Main	
varlist(*varlist*)	display marginal effects for *varlist*
at(median [*atlist*])	calculate marginal effects at these values
rank(*ranklist*)	calculate marginal effects for the simulated probability of these ranked alternatives
Options	
level(#)	set confidence interval level; default is level(95)
nodiscrete	treat indicator variables as continuous
noesample	do not restrict calculation of the medians to the estimation sample
nowght	ignore weights when calculating medians

Menu

Statistics > Postestimation > Reports and statistics

Options for estat mfx

Main

varlist(*varlist*) specifies the variables for which to display marginal effects. The default is all variables.

at(median [*atlist*]) specifies the values at which the marginal effects are to be calculated. *atlist* is

[[*alternative*:*variable* = #] [*variable* = #] [...]])

The marginal effects are calculated at the medians of the independent variables.

After specifying the summary statistic, you can specify specific values for variables. You can specify values for alternative-specific variables by alternative, or you can specify one value for all alternatives. You can specify only one value for case-specific variables. For example, in the wlsrank dataset, female and score are case-specific variables, whereas high and low are alternative-specific variables. The following would be a legal syntax for estat mfx:

```
. estat mfx, at(median high=0 esteem:high=1 low=0 security:low=1 female=1)
```

When nodiscrete is not specified, at(median [*atlist*]) has no effect on computing marginal effects for indicator variables, which are calculated as the discrete change in the simulated probability as the indicator variable changes from 0 to 1.

The median computations respect any if or in qualifiers, so you can restrict the data over which the medians are computed. You can even restrict the values to a specific case, for example,

```
. estat mfx if case==13
```

rank(*ranklist*) specifies the ranks for the alternatives. *ranklist* is

alternative = # *alternative* = # [...])

The default is to rank the calculated latent variables. Alternatives excluded from `rank()` are omitted from the analysis. You must therefore specify at least two alternatives in `rank()`. You may have tied ranks in the rank specification. Only the order in the ranks is relevant.

Options

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`nodiscrete` specifies that indicator variables be treated as continuous variables. An indicator variable is one that takes on the value 0 or 1 in the estimation sample. By default, the discrete change in the simulated probability is computed as the indicator variable changes from 0 to 1.

`noesample` specifies that the whole dataset be considered instead of only those marked in the `e(sample)` defined by the `asroprobit` command.

`nowght` specifies that weights be ignored when calculating the medians.

Remarks

Remarks are presented under the following headings:

Predicted probabilities
Obtaining estimation statistics

Predicted probabilities

After fitting an alternative-specific rank-ordered probit model, you can use `predict` to obtain the probabilities of alternative rankings or the probabilities of each alternative being preferred. When evaluating the multivariate normal probabilities via (quasi) Monte Carlo, `predict` uses the same method to generate the (quasi) random sequence of numbers as the previous call to `asroprobit`. For example, if you specified `intmethod(halton)` when fitting the model, `predict` also uses Halton sequences.

▷ Example 1

In example 1 of [R] **asroprobit**, we fit a model of job characteristic preferences. This is a study of 1957 Wisconsin high school graduates that were asked to rate their relative preference of four job characteristics: esteem, a job other people regard highly; variety, a job that is not repetitive and allows you to do a variety of things; autonomy, a job where your supervisor does not check on you frequently; and security, a job with a low risk of being laid off. The case-specific covariates are gender, `female`, an indicator variable for females, and `score`, a score on a general mental ability test measured in standard deviations. The alternative-specific variables are `high` and `low`, which indicate whether the respondent's current job is high or low in esteem, variety, autonomy, or security. This approach provides three states for a respondent's current job status for each alternative, $(1,0)$, $(0,1)$, and $(0,0)$, using the notation (`high`, `low`). The score $(1,1)$ is omitted because the respondent's current job cannot be considered both high and low in one of the job characteristics. The $(0,0)$ score would indicate that the respondent's current job does not rank high or low (is neutral) in a job characteristic. The alternatives are ranked such that 1 is the preferred alternative and 4 is the least preferred.

We can obtain the probabilities of the observed alternative rankings, the `pr` option, and the probability of each alternative being preferred, the `pr1` option, by using `predict`:

```
. use http://www.stata-press.com/data/r12/wlsrank
(1992 Wisconsin Longitudinal Study data on job values)
. asroprobit rank high low if noties, case(id) alternatives(jobchar)
> casevars(female score) reverse
  (output omitted)
. keep if e(sample)
(11244 observations deleted)
. predict prob, pr
. predict prob1, pr1
. list id jobchar prob prob1 rank female score high low in 1/12
```

	id	jobchar	prob	prob1	rank	female	score	high	low
1.	13	security	.0421807	.2784269	3	0	.3246512	0	1
2.	13	autonomy	.0421807	.1029036	1	0	.3246512	0	0
3.	13	variety	.0421807	.6026725	2	0	.3246512	1	0
4.	13	esteem	.0421807	.0160111	4	0	.3246512	0	1
5.	19	autonomy	.0942025	.1232488	4	1	.0492111	0	0
6.	19	esteem	.0942025	.0140261	3	1	.0492111	0	0
7.	19	security	.0942025	.4601368	1	1	.0492111	1	0
8.	19	variety	.0942025	.4025715	2	1	.0492111	0	0
9.	22	esteem	.1414177	.0255264	4	1	1.426412	1	0
10.	22	variety	.1414177	.4549441	1	1	1.426412	0	0
11.	22	security	.1414177	.2629494	3	1	1.426412	0	0
12.	22	autonomy	.1414177	.2566032	2	1	1.426412	1	0

The `prob` variable is constant for each case because it contains the probability of the ranking in the `rank` variable. On the other hand, the `prob1` variable contains the estimated probability of each alternative being preferred. For each case, the sum of the values in `prob1` will be approximately 1.0. They do not add up to exactly 1.0 because of approximations due to the GHK algorithm.

◁

Obtaining estimation statistics

For examples of the specialized `estat` subcommands `covariance` and `correlation`, see [R] **asmprobit postestimation**. The entry also has a good example of computing marginal effects after `asmprobit` that is applicable to `asroprobit`. Below we will elaborate further on marginal effects after `asroprobit` where we manipulate the `rank()` option.

▷ Example 2

We will continue with the preferred job characteristics example where we first compute the marginal effects for case `id` = 13.

```
. estat mfx if id==13, rank(security=3 autonomy=1 variety=2 esteem=4)

Pr(esteem=4 variety=2 autonomy=1 security=3) = .04218068
```

variable	dp/dx	Std. Err.	z	P>|z|	[	95% C.I.	]	X
high*								
esteem	-.008713	.001964	-4.44	0.000	-.012562	-.004864		0
variety	-.009102	.003127	-2.91	0.004	-.015231	-.002973		1
autonomy	.025535	.007029	3.63	0.000	.011758	.039313		0
security	-.003745	.001394	-2.69	0.007	-.006477	-.001013		0
low*								
esteem	.001614	.002646	0.61	0.542	-.003572	.0068		1
variety	.001809	.003012	0.60	0.548	-.004094	.007712		0
autonomy	-.003849	.006104	-0.63	0.528	-.015813	.008115		0
security	.000582	.000985	0.59	0.554	-.001348	.002513		1
casevars								
female*	.009767	.009064	1.08	0.281	-.007998	.027533		0
score	.008587	.004488	1.91	0.056	-.00021	.017384		.32465

```
(*) dp/dx is for discrete change of indicator variable from 0 to 1
```

Next we compute the marginal effects for the probability that autonomy is preferred given the profile of case `id` = 13.

```
. estat mfx if id==13, rank(security=2 autonomy=1 variety=2 esteem=2)

Pr(esteem=3 variety=4 autonomy=1 security=2) +
Pr(esteem=4 variety=3 autonomy=1 security=2) +
Pr(esteem=2 variety=4 autonomy=1 security=3) +
Pr(esteem=4 variety=2 autonomy=1 security=3) +
Pr(esteem=2 variety=3 autonomy=1 security=4) +
Pr(esteem=3 variety=2 autonomy=1 security=4) = .10276103
```

variable	dp/dx	Std. Err.	z	P>|z|	[	95% C.I.	]	X
high*								
esteem	-.003524	.001258	-2.80	0.005	-.005989	-.001059		0
variety	-.036203	.00894	-4.05	0.000	-.053724	-.018681		1
autonomy	.057279	.013801	4.15	0.000	.030231	.084328		0
security	-.0128	.002665	-4.80	0.000	-.018024	-.007576		0
low*								
esteem	.000518	.000833	0.62	0.534	-.001116	.002151		1
variety	.006409	.010588	0.61	0.545	-.014343	.027161		0
autonomy	-.008818	.013766	-0.64	0.522	-.035799	.018163		0
security	.002314	.003697	0.63	0.531	-.004932	.009561		1
casevars								
female*	.013839	.021607	0.64	0.522	-.028509	.056188		0
score	.017917	.011062	1.62	0.105	-.003764	.039598		.32465

```
(*) dp/dx is for discrete change of indicator variable from 0 to 1
```

The probability computed by `estat mfx` matches the probability computed by `predict, pr1` only within three digits. This outcome is because of how the computation is carried out and the numeric inaccuracy of the GHK simulator using a Hammersley point set of length 200. The computation carried out by `estat mfx` literally computes all six probabilities listed in the header of the MFX table and sums them. The computation by `predict, pr1` is the same as `predict` after `asmprobit` (multinomial probit): it computes the probability that `autonomy` is chosen, thus requiring only one

call to the GHK simulator. Hence, there is a difference in the reported values even though the two probability statements are equivalent.

◁

Saved results

`estat mfx` saves the following in `r()`:

Scalars

`r(pr)` scalar containing the computed probability of the ranked alternatives.

Matrices

`r(ranks)` column vector containing the alternative ranks. The rownames identify the alternatives.

`r(mfx)` matrix containing the computed marginal effects and associated statistics. Column 1 of the matrix contains the marginal effects; column 2, their standard errors; column 3, their z statistics; and columns 4 and 5, the confidence intervals. Column 6 contains the values of the independent variables used to compute the probabilities `r(pr)`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

BIC note — Calculating and interpreting BIC

Description

This entry discusses a statistical issue that arises when using the Bayesian information criterion (BIC) to compare models.

Stata calculates BIC, assuming $N =$ `e(N)`—we will explain—but sometimes it would be better if a different N were used. Commands that calculate BIC have an `n()` option, allowing you to specify the N to be used.

In summary,

1. If you are comparing results estimated by the same estimation command, using the default BIC calculation is probably fine. There is an issue, but most researchers would ignore it.
2. If you are comparing results estimated by different estimation commands, you need to be on your guard.
    a. If the different estimation commands share the same definitions of observations, independence, and the like, you are back in case 1.
    b. If they differ in these regards, you need to think about the value of N that should be used. For example, `logit` and `xtlogit` differ in that the former assumes independent observations and the latter, independent panels.
    c. If estimation commands differ in the events being used over which the likelihood function is calculated, the information criteria may not be comparable at all. We say information *criteria* because this would apply equally to the Akaike information criterion (AIC), as well as to BIC. For instance, `streg` and `stcox` produce such incomparable results. The events used by `streg` are the actual survival times, whereas the events used by `stcox` are failures within risk pools, conditional on the times at which failures occurred.

Remarks

Remarks are presented under the following headings:

Background
The problem of determining N
The problem of conformable likelihoods
The first problem does not arise with AIC; the second problem does
Calculating BIC correctly

Background

The AIC and the BIC are two popular measures for comparing maximum likelihood models. AIC and BIC are defined as

$$\text{AIC} = -2 \times \ln(\text{likelihood}) + 2 \times k$$

$$\text{BIC} = -2 \times \ln(\text{likelihood}) + \ln(N) \times k$$

where

$$k = \text{number of parameters estimated}$$

$$N = \text{number of observations}$$

We are going to discuss AIC along with BIC because AIC has some of the problems that BIC has, but not all.

AIC and BIC can be viewed as measures that combine fit and complexity. Fit is measured negatively by $-2 \times \ln(\text{likelihood})$; the larger the value, the worse the fit. Complexity is measured positively, either by $2 \times k$ (AIC) or $\ln(N) \times k$ (BIC).

Given two models fit on the same data, the model with the smaller value of the information criterion is considered to be better.

There is substantial literature on these measures: see Akaike (1974); Raftery (1995); Sakamoto, Ishiguro, and Kitagawa (1986); and Schwarz (1978).

When Stata calculates the above measures, it uses the rank of `e(V)` for k and it uses `e(N)` for N. `e(V)` and `e(N)` are Stata notation for results stored by the estimation command. `e(V)` is the variance–covariance matrix of the estimated parameters, and `e(N)` is the number of observations in the dataset used in calculating the result.

The problem of determining N

The difference between AIC and BIC is that AIC uses the constant 2 to weight k, whereas BIC uses $\ln(N)$.

Determining what value of N should be used is problematic. Despite appearances, the definition "N is the number of observations" is not easy to make operational. N does not appear in the likelihood function itself, N is not the output of a standard statistical formula, and what is an observation is often subjective.

▷ Example 1

Often what is meant by N is obvious. Consider a simple logit model. What is meant by N is the number of observations that are statistically independent and that corresponds to M, the number of observations in the dataset used in the calculation. We will write $N = M$.

But now assume that the same dataset has a grouping variable and the data are thought to be clustered within group. To keep the problem simple, let's pretend that there are G groups and m observations within group, so that $M = G \times m$. Because you are worried about intragroup correlation, you fit your model with `xtlogit`, grouping on the grouping variable. Now you wish to calculate BIC. What is the N that should be used? $N = M$ or $N = G$?

That is a deep question. If the observations really are independent, then you should use $N = M$. If the observations within group are not just correlated but are duplicates of one another, and they had to be so, then you should use $N = G$. Between those two extremes, you should probably use a number between N and G, but determining what that number should be from measured correlations is difficult. Using $N = M$ is conservative in that, if anything, it overweights complexity. Conservativeness, however, is subjective, too: using $N = G$ could be considered more conservative in that fewer constraints are being placed on the data.

When the estimated correlation is high, our reaction would be that using $N = G$ is probably more reasonable. Our first reaction, however, would be that using BIC to compare models is probably a misuse of the measure.

Stata uses $N = M$. An informal survey of web-based literature suggests that $N = M$ is the popular choice.

There is another reason, not so good, to choose $N = M$. It makes across-model comparisons more likely to be valid when performed without thinking about the issue. Say that you wish to compare the `logit` and `xtlogit` results. Thus you need to calculate

$$\text{BIC}_p = -2 \times \ln(\text{likelihood}_p) + \ln(N_p) \times k$$

$$\text{BIC}_x = -2 \times \ln(\text{likelihood}_x) + \ln(N_x) \times k$$

Whatever N you use, you must use the same N in both formulas. Stata's choice of $N = M$ at least meets that test.

◁

▷ Example 2

In the above example, using $N = M$ is reasonable. Now let's look at when using $N = M$ is wrong, even if popular.

Consider a model fit by `stcox`. Using $N = M$ is certainly wrong if for no other reason than M is not even a well-defined number. The same data can be represented by different datasets with different numbers of observations. For example, in one dataset, there might be 1 observation per subject. In another, the same subjects could have two records each, the first recording the first half of the time at risk and the second recording the remaining part. All statistics calculated by Stata on either dataset would be the same, but M would be different.

Deciding on the right definition, however, is difficult. Viewed one way, N in the Cox regression case should be the number of risk pools, R, because the Cox regression calculation is made on the basis of the independent risk pools. Viewed another way, N should be the number of subjects, N_{subj}, because, even though the likelihood function is based on risk pools, the parameters estimated are at the subject level.

You can decide which argument you prefer.

For parametric survival models, in single-record data, $N = M$ is unambiguously correct. For multirecord data, there is an argument for $N = M$ and for $N = N_{\text{subj}}$.

◁

The problem of conformable likelihoods

The problem of conformable likelihoods does not concern N. Researchers sometimes use information criteria such as BIC and AIC to make comparisons across models. For that to be valid, the likelihoods must be conformable; that is, the likelihoods must all measure the same thing.

It is common to think of the likelihood function as the $\Pr(\text{data} \mid \text{parameters})$, but in fact, the likelihood is

$$\Pr(\text{particular events in the data} \mid \text{parameters})$$

You must ensure that the events are the same.

For instance, they are not the same in the semiparametric Cox regression and the various parametric survival models. In Cox regression, the events are, at each failure time, that the subjects observed to fail in fact failed, given that failures occurred at those times. In the parametric models, the events are that each subject failed exactly when the subject was observed to fail.

The formula for AIC and BIC is

$$\text{measure} = -2 \times \ln(\text{likelihood}) + \text{complexity}$$

When you are comparing models, if the likelihoods are measuring different events, even if the models obtain estimates of the same parameters, differences in the information measures are irrelevant.

The first problem does not arise with AIC; the second problem does

Regardless of model, the problem of defining N never arises with AIC because N is not used in the AIC calculation. AIC uses a constant 2 to weight complexity as measured by k, rather than $\ln(N)$.

For both AIC and BIC, however, the likelihood functions must be conformable; that is, they must be measuring the same event.

Calculating BIC correctly

When using BIC to compare results, and especially when using BIC to compare results from different models, you should think carefully about how N should be defined. Then specify that number by using the `n()` option:

```
. estimates stats full sub, n(74)
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
full	102	-45.03321	-20.59083	4	49.18167	58.39793
sub	102	-45.03321	-27.17516	3	60.35031	67.26251

Note: N = 74 used in calculating BIC

Both `estimates stats` and `estat ic` allow the `n()` option; see [R] **estimates stats** and [R] **estat**.

Methods and formulas

AIC and BIC are defined as

$$\text{AIC} = -2 \times \ln(\text{likelihood}) + 2 \times k$$

$$\text{BIC} = -2 \times \ln(\text{likelihood}) + \ln(N) \times k$$

where k is the model degrees of freedom calculated as the rank of variance–covariance matrix of the parameters `e(V)` and N is the number of observations used in estimation or, more precisely, the number of independent terms in the likelihood. Operationally, N is defined as `e(N)` unless the `n()` option is specified.

Title

binreg — Generalized linear models: Extensions to the binomial family

Syntax

`binreg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`noconstant`	suppress constant term
`or`	use logit link and report odds ratios
`rr`	use log link and report risk ratios
`hr`	use log-complement link and report health ratios
`rd`	use identity link and report risk differences
`n(#|`*varname*`)`	use # or *varname* for number of trials
`exposure(`*varname*`)`	include ln(*varname*) in model with coefficient constrained to 1
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
`mu(`*varname*`)`	use *varname* as the initial estimate for the mean of *depvar*
`init(`*varname*`)`	synonym for `mu(`*varname*`)`
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `eim`, `robust`, `cluster` *clustvar*, `oim`, `opg`, `bootstrap`, `jackknife`, `hac` *kernel*, `jackknife1`, or `unbiased`
`t(`*varname*`)`	variable name corresponding to time
`vfactor(#)`	multiply variance matrix by scalar #
`disp(#)`	quasi-likelihood multiplier
`scale(x2|dev|#)`	set the scale parameter; default is `scale(1)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`coefficients`	report nonexponentiated coefficients
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
`irls`	use iterated, reweighted least-squares optimization; the default
`ml`	use maximum likelihood optimization
maximize_options	control the maximization process; seldom used
`fisher(#)`	Fisher scoring steps
`search`	search for good starting values
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`bootstrap`, `by`, `jackknife`, `mi estimate`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.
`vce(bootstrap)`, `vce(jackknife)`, and `vce(jackknife1)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.
`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Generalized linear models > GLM for the binomial family

Description

`binreg` fits generalized linear models for the binomial family. It estimates odds ratios, risk ratios, health ratios, and risk differences. The available links are

Option	Implied link	Parameter
`or`	`logit`	odds ratios = exp(β)
`rr`	`log`	risk ratios = exp(β)
`hr`	`log complement`	health ratios = exp(β)
`rd`	`identity`	risk differences = β

Estimates of odds, risk, and health ratios are obtained by exponentiating the appropriate coefficients. The `or` option produces the same results as Stata's `logistic` command, and `or coefficients` yields the same results as the `logit` command. When no link is specified, `or` is assumed.

Options

Model

`noconstant`; see [R] **estimation options**.

`or` requests the logit link and results in odds ratios if `coefficients` is not specified.

`rr` requests the log link and results in risk ratios if `coefficients` is not specified.

`hr` requests the log-complement link and results in health ratios if `coefficients` is not specified.

`rd` requests the identity link and results in risk differences.

`n(#|`*varname*`)` specifies either a constant integer to use as the denominator for the binomial family or a variable that holds the denominator for each observation.

`exposure(`*varname*`)`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**. `constraints(`*constraints*`)` and `collinear` are not allowed with `irls`.

`mu(`*varname*`)` specifies *varname* containing an initial estimate for the mean of *depvar*. This option can be useful if you encounter convergence difficulties. `init(`*varname*`)` is a synonym.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification, that allow for intragroup correlation, that are derived from asymptotic theory, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(eim)`, the default, uses the expected information matrix (EIM) for the variance estimator.

`binreg` also allows the following:

`vce(hac` *kernel* [*#*]`)` specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels built into `binreg`. *kernel* is a user-written program or one of

`nwest` | `gallant` | `anderson`

If *#* is not specified, $N - 2$ is assumed.

`vce(jackknife1)` specifies that the one-step jackknife estimate of variance be used.

`vce(unbiased)` specifies that the unbiased sandwich estimate of variance be used.

`t(`*varname*`)` specifies the variable name corresponding to time; see [TS] **tsset**. `binreg` does not always need to know `t()`, though it does if `vce(hac ...)` is specified. Then you can either specify the time variable with `t()`, or you can `tsset` your data before calling `binreg`. When the time variable is required, `binreg` assumes that the observations are spaced equally over time.

`vfactor(#)` specifies a scalar by which to multiply the resulting variance matrix. This option allows users to match output with other packages, which may apply degrees of freedom or other small-sample corrections to estimates of variance.

`disp(#)` multiplies the variance of *depvar* by *#* and divides the deviance by *#*. The resulting distributions are members of the quasilikelihood family.

`scale(x2` | `dev` | `#)` overrides the default scale parameter. This option is allowed only with Hessian (information matrix) variance estimates.

By default, `scale(1)` is assumed for the discrete distributions (binomial, Poisson, and negative binomial), and `scale(x2)` is assumed for the continuous distributions (Gaussian, gamma, and inverse Gaussian).

`scale(x2)` specifies that the scale parameter be set to the Pearson chi-squared (or generalized chi-squared) statistic divided by the residual degrees of freedom, which was recommended by McCullagh and Nelder (1989) as a good general choice for continuous distributions.

`scale(dev)` sets the scale parameter to the deviance divided by the residual degrees of freedom. This option provides an alternative to `scale(x2)` for continuous distributions and overdispersed or underdispersed discrete distributions.

`scale(#)` sets the scale parameter to *#*.

Reporting

`level(#)`, `noconstant`; see [R] **estimation options**.

`coefficients` displays the nonexponentiated coefficients and corresponding standard errors and confidence intervals. This option has no effect when the `rd` option is specified, because it always presents the nonexponentiated coefficients.

`nocnsreport`; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

irls requests iterated, reweighted least-squares (IRLS) optimization of the deviance instead of Newton–Raphson optimization of the log likelihood. This option is the default.

ml requests that optimization be carried out by using Stata's ml command; see [R] **ml**.

maximize_options: technique(*algorithm_spec*), [no]log, trace, gradient, showstep, hessian, showtolerance, difficult, iterate(#), tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

Setting the optimization method to ml, with technique() set to something other than BHHH, changes the *vcetype* to vce(oim). Specifying technique(bhhh) changes *vcetype* to vce(opg).

fisher(#) specifies the number of Newton–Raphson steps that should use the Fisher scoring Hessian or EIM before switching to the observed information matrix (OIM). This option is available only if ml is specified and is useful only for Newton–Raphson optimization.

search specifies that the command search for good starting values. This option is available only if ml is specified and is useful only for Newton–Raphson optimization.

The following option is available with binreg but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Remarks

Wacholder (1986) suggests methods for estimating risk ratios and risk differences from prospective binomial data. These estimates are obtained by selecting the proper link functions in the generalized linear-model framework. (See *Methods and formulas* for details; also see [R] **glm**.)

▷ Example 1

Wacholder (1986) presents an example, using data from Wright et al. (1983), of an investigation of the relationship between alcohol consumption and the risk of a low-birthweight baby. Covariates examined included whether the mother smoked (yes or no), mother's social class (three levels), and drinking frequency (light, moderate, or heavy). The data for the 18 possible categories determined by the covariates are illustrated below.

Let's first describe the data and list a few observations.

```
. use http://www.stata-press.com/data/r12/binreg
. list
```

	cat	d	n	alc	smo	soc
1.	1	11	84	3	1	1
2.	2	5	79	2	1	1
3.	3	11	169	1	1	1
4.	4	6	28	3	2	1
5.	5	3	13	2	2	1
6.	6	1	26	1	2	1
7.	7	4	22	3	1	2
8.	8	3	25	2	1	2
9.	9	12	162	1	1	2
10.	10	4	17	3	2	2
11.	11	2	7	2	2	2
12.	12	6	38	1	2	2
13.	13	0	14	3	1	3
14.	14	1	18	2	1	3
15.	15	12	91	1	1	3
16.	16	7	19	3	2	3
17.	17	2	18	2	2	3
18.	18	8	70	1	2	3

Each observation corresponds to one of the 18 covariate structures. The number of low-birthweight babies from `n` in each category is given by the `d` variable.

We begin by estimating risk ratios:

```
. binreg d i.soc i.alc i.smo, n(n) rr
Iteration 1:   deviance =   14.2879
Iteration 2:   deviance =    13.607
Iteration 3:   deviance =  13.60503
Iteration 4:   deviance =  13.60503
Generalized linear models                         No. of obs      =         18
Optimization     : MQL Fisher scoring             Residual df     =         12
                   (IRLS EIM)                     Scale parameter =          1
Deviance         =   13.6050268                   (1/df) Deviance =   1.133752
Pearson          =  11.51517095                   (1/df) Pearson  =   .9595976
Variance function: V(u) = u*(1-u/n)               [Binomial]
Link function    : g(u) = ln(u/n)                 [Log]
                                                  BIC             = -21.07943
```

d	Risk Ratio	EIM Std. Err.	z	P>|z|	[95% Conf.	Interval]
soc						
2	1.340001	.3127382	1.25	0.210	.848098	2.11721
3	1.349487	.3291488	1.23	0.219	.8366715	2.176619
alc						
2	1.191157	.3265354	0.64	0.523	.6960276	2.038503
3	1.974078	.4261751	3.15	0.002	1.293011	3.013884
2.smo	1.648444	.332875	2.48	0.013	1.109657	2.448836
_cons	.0630341	.0128061	-13.61	0.000	.0423297	.0938656

By default, Stata reports the risk ratios (the exponentiated regression coefficients) estimated by the model. We can see that the risk ratio comparing heavy drinkers with light drinkers, after adjusting for smoking and social class, is 1.974078. That is, mothers who drink heavily during their pregnancy have approximately twice the risk of delivering low-birthweight babies as mothers who are light drinkers.

The nonexponentiated coefficients can be obtained with the `coefficients` option:

```
. binreg d i.soc i.alc i.smo, n(n) rr coefficients

Iteration 1:   deviance =   14.2879
Iteration 2:   deviance =    13.607
Iteration 3:   deviance =  13.60503
Iteration 4:   deviance =  13.60503

Generalized linear models                         No. of obs      =        18
Optimization     : MQL Fisher scoring             Residual df     =        12
                   (IRLS EIM)                     Scale parameter =         1
Deviance         =   13.6050268                   (1/df) Deviance =  1.133752
Pearson          =  11.51517095                   (1/df) Pearson  =  .9595976

Variance function: V(u) = u*(1-u/n)               [Binomial]
Link function    : g(u) = ln(u/n)                 [Log]

                                                  BIC             = -21.07943
```

d	EIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]

_cons	.059028	.0160693	3.67	0.000	.0275327	.0905232

The risk difference between heavy drinkers and light drinkers is simply the value of the coefficient for `3.alc` $= 0.0801291$. Because the risk differences are obtained directly from the coefficients estimated by using the identity link, the `coefficients` option has no effect here.

Health ratios are obtained with the `hr` option. The health ratios (exponentiated coefficients for the log-complement link) are reported directly.

To see the nonexponentiated coefficients, we can specify the `coefficients` option. ◁

Saved results

`binreg, irls` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(k)`	number of parameters
`e(k_eq_model)`	number of equations in overall model test
`e(df_m)`	model degrees of freedom
`e(df)`	residual degrees of freedom
`e(phi)`	model scale parameter
`e(disp)`	dispersion parameter
`e(bic)`	model BIC
`e(N_clust)`	number of clusters
`e(deviance)`	deviance
`e(deviance_s)`	scaled deviance
`e(deviance_p)`	Pearson deviance
`e(deviance_ps)`	scaled Pearson deviance
`e(dispers)`	dispersion
`e(dispers_s)`	scaled dispersion
`e(dispers_p)`	Pearson dispersion
`e(dispers_ps)`	scaled Pearson dispersion
`e(vf)`	factor set by `vfactor()`, `1` if not set
`e(rank)`	rank of `e(V)`
`e(rc)`	return code

Macros

`e(cmd)`	`binreg`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(eform)`	`eform()` option implied by `or`, `rr`, `hr`, or `rd`
`e(varfunc)`	program to calculate variance function
`e(varfunct)`	variance title
`e(varfuncf)`	variance function
`e(link)`	program to calculate link function
`e(linkt)`	link title
`e(linkf)`	link function
`e(m)`	number of binomial trials
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title_fl)`	family–link title
`e(clustvar)`	name of cluster variable
`e(offset)`	linear offset variable
`e(cons)`	`noconstant` or not set
`e(hac_kernel)`	HAC kernel
`e(hac_lag)`	HAC lag
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(opt)`	type of optimization
`e(opt1)`	optimization title, line 1
`e(opt2)`	optimization title, line 2
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(marginsok)`	predictions allowed by `margins`
`e(marginsnotok)`	predictions disallowed by `margins`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

binreg, ml saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(df)	residual degrees of freedom
e(phi)	model scale parameter
e(aic)	model AIC, if ml
e(bic)	model BIC
e(ll)	log likelihood, if ml
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance of model test
e(deviance)	deviance
e(deviance_s)	scaled deviance
e(deviance_p)	Pearson deviance
e(deviance_ps)	scaled Pearson deviance
e(dispers)	dispersion
e(dispers_s)	scaled dispersion
e(dispers_p)	Pearson dispersion
e(dispers_ps)	scaled Pearson dispersion
e(vf)	factor set by vfactor(), 1 if not set
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	binreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(eform)	eform() option implied by or, rr, hr, or rd
e(varfunc)	program to calculate variance function
e(varfunct)	variance title
e(varfuncf)	variance function
e(link)	program to calculate link function
e(linkt)	link title
e(linkf)	link function
e(m)	number of binomial trials
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(title_fl)	family–link title
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(cons)	noconstant or not set
e(hac_kernel)	HAC kernel
e(hac_lag)	HAC lag
e(chi2type)	Wald; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(opt1)	optimization title, line 1
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

binreg is implemented as an ado-file.

Let π_i be the probability of success for the ith observation, $i = 1, \ldots, N$, and let $X\beta$ be the linear predictor. The link function relates the covariates of each observation to its respective probability through the linear predictor.

In logistic regression, the logit link is used:

$$\ln\left(\frac{\pi}{1-\pi}\right) = X\beta$$

The regression coefficient β_k represents the change in the logarithm of the odds associated with a one-unit change in the value of the X_k covariate; thus $\exp(\beta_k)$ is the ratio of the odds associated with a change of one unit in X_k.

For risk differences, the identity link $\pi = X\beta$ is used. The regression coefficient β_k represents the risk difference associated with a change of one unit in X_k. When using the identity link, you can obtain fitted probabilities outside the interval $(0, 1)$. As suggested by Wacholder, at each iteration, fitted probabilities are checked for range conditions (and put back in range if necessary). For example, if the identity link results in a fitted probability that is smaller than 1e–4, the probability is replaced with 1e–4 before the link function is calculated.

A similar adjustment is made for the logarithmic link, which is used for estimating the risk ratio, $\ln(\pi) = X\beta$, where $\exp(\beta_k)$ is the risk ratio associated with a change of one unit in X_k, and for the log-complement link used to estimate the probability of no disease or health, where $\exp(\beta_k)$ represents the "health ratio" associated with a change of one unit in X_k.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

Title

binreg postestimation — Postestimation tools for binreg

Description

The following postestimation commands are available after `binreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

statistic	Description
Main	
`mu`	expected value of y; the default
`xb`	linear prediction $\eta = \mathbf{x}\widehat{\boldsymbol{\beta}}$
`eta`	synonym for `xb`
`stdp`	standard error of the linear prediction
`anscombe`	Anscombe (1953) residuals
`cooksd`	Cook's distance
`deviance`	deviance residuals
`hat`	diagonals of the "hat" matrix as an analog to simple linear regression
`likelihood`	weighted average of the standardized deviance and standard Pearson residuals
`pearson`	Pearson residuals
`response`	differences between the observed and fitted outcomes
`score`	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$
`working`	working residuals

options	Description
Options	
`nooffset`	modify calculations to ignore the offset variable
`adjusted`	adjust deviance residual to speed up convergence
`standardized`	multiply residual by the factor $(1-h)^{1/2}$
`studentized`	multiply residual by one over the square root of the estimated scale parameter
`modified`	modify denominator of residual to be a reasonable estimate of the variance of *depvar*

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`mu`, the default, specifies that `predict` calculate the expected value of y, equal to $g^{-1}(\mathbf{x}\widehat{\boldsymbol{\beta}})$ [$ng^{-1}(\mathbf{x}\widehat{\boldsymbol{\beta}})$ for the binomial family].

`xb` calculates the linear prediction $\eta = \mathbf{x}\widehat{\boldsymbol{\beta}}$.

`eta` is a synonym for `xb`.

`stdp` calculates the standard error of the linear prediction.

`anscombe` calculates the Anscombe (1953) residuals to produce residuals that closely follow a normal distribution.

`cooksd` calculates Cook's distance, which measures the aggregate change in the estimated coefficients when each observation is left out of the estimation.

`deviance` calculates the deviance residuals, which are recommended by McCullagh and Nelder (1989) and others as having the best properties for examining goodness of fit of a GLM. They are approximately normally distributed if the model is correct and may be plotted against the fitted values or against a covariate to inspect the model's fit. Also see the `pearson` option below.

`hat` calculates the diagonals of the "hat" matrix as an analog to simple linear regression.

`likelihood` calculates a weighted average of the standardized deviance and standardized Pearson (described below) residuals.

`pearson` calculates the Pearson residuals, which often have markedly skewed distributions for nonnormal family distributions. Also see the `deviance` option above.

`response` calculates the differences between the observed and fitted outcomes.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

`working` calculates the working residuals, which are response residuals weighted according to the derivative of the link function.

Options

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `binreg`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`adjusted` adjusts the deviance residual to make the convergence to the limiting normal distribution faster. The adjustment deals with adding to the deviance residual a higher-order term depending on the variance function family. This option is allowed only when `deviance` is specified.

`standardized` requests that the residual be multiplied by the factor $(1 - h)^{-1/2}$, where h is the diagonal of the hat matrix. This step is done to take into account the correlation between *depvar* and its predicted value.

`studentized` requests that the residual be multiplied by one over the square root of the estimated scale parameter.

`modified` requests that the denominator of the residual be modified to be a reasonable estimate of the variance of *depvar*. The base residual is multiplied by the factor $(k/w)^{-1/2}$, where k is either one or the user-specified dispersion parameter and w is the specified weight (or one if left unspecified).

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar$_1$, *depvar*$_2$, *indepvars*, and *depvar* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
vce(), noskip, and weights are not allowed with the svy prefix; see [SVY] **svy**.
pweights, fweights, and iweights are allowed; see [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

biprobit

Statistics > Binary outcomes > Bivariate probit regression

seemingly unrelated biprobit

Statistics > Binary outcomes > Seemingly unrelated bivariate probit regression

Description

biprobit fits maximum-likelihood two-equation probit models—either a bivariate probit or a seemingly unrelated probit (limited to two equations).

Options

Model

`noconstant`; see [R] **estimation options**.

`partial` specifies that the partial observability model be fit. This particular model commonly has poor convergence properties, so we recommend that you use the `difficult` option if you want to fit the Poirier partial observability model; see [R] **maximize**.

This model computes the product of the two dependent variables so that you do not have to replace each with the product.

`offset1(`*varname*`)`, `offset2(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`noskip` specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test of all the parameters in the regression equation being zero (except the constant). For many models, this option can substantially increase estimation time.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `biprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

For a good introduction to the bivariate probit models, see Greene (2012, 738–752) and Pindyck and Rubinfeld (1998). Poirier (1980) explains the partial observability model. Van de Ven and Van Pragg (1981) explain the probit model with sample selection; see [R] **heckprob** for details.

▷ Example 1

We use the data from Pindyck and Rubinfeld (1998, 332). In this dataset, the variables are whether children attend private school (`private`), number of years the family has been at the present residence (`years`), log of property tax (`logptax`), log of income (`loginc`), and whether the head of the household voted for an increase in property taxes (`vote`).

We wish to model the bivariate outcomes of whether children attend private school and whether the head of the household voted for an increase in property tax based on the other covariates.

                                                Wald chi2(6)    =       9.59
Log likelihood = -89.254028                     Prob > chi2     =     0.1431
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
private						
years	-.0118884	.0256778	-0.46	0.643	-.0622159	.0384391
logptax	-.1066962	.6669782	-0.16	0.873	-1.413949	1.200557
loginc	.3762037	.5306484	0.71	0.478	-.663848	1.416255
_cons	-4.184694	4.837817	-0.86	0.387	-13.66664	5.297253
vote						
years	-.0168561	.0147834	-1.14	0.254	-.0458309	.0121188
logptax	-1.288707	.5752266	-2.24	0.025	-2.416131	-.1612839
loginc	.998286	.4403565	2.27	0.023	.1352031	1.861369
_cons	-.5360573	4.068509	-0.13	0.895	-8.510188	7.438073
/athrho	-.2764525	.2412099	-1.15	0.252	-.7492153	.1963102
rho	-.2696186	.2236753			-.6346806	.1938267

```
Likelihood-ratio test of rho=0:     chi2(1) =  1.38444    Prob > chi2 = 0.2393
```

The output shows several iteration logs. The first iteration log corresponds to running the univariate probit model for the first equation, and the second log corresponds to running the univariate probit for the second model. If $\rho = 0$, the sum of the log likelihoods from these two models will equal the log likelihood of the bivariate probit model; this sum is printed in the iteration log as the comparison log likelihood.

The final iteration log is for fitting the full bivariate probit model. A likelihood-ratio test of the log likelihood for this model and the comparison log likelihood is presented at the end of the output. If we had specified the `vce(robust)` option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

We could have fit the same model by using the seemingly unrelated syntax as

```
. biprobit (private=years logptax loginc) (vote=years logptax loginc)
```

◁

Saved results

`biprobit` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(k)`	number of parameters
`e(k_eq)`	number of equations in `e(b)`
`e(k_aux)`	number of auxiliary parameters
`e(k_eq_model)`	number of equations in overall model test
`e(k_dv)`	number of dependent variables
`e(df_m)`	model degrees of freedom
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model (`noskip` only)
`e(ll_c)`	log likelihood, comparison model
`e(N_clust)`	number of clusters
`e(chi2)`	χ^2
`e(chi2_c)`	χ^2 for comparison test
`e(p)`	significance
`e(rho)`	ρ
`e(rank)`	rank of `e(V)`
`e(rank0)`	rank of `e(V)` for constant-only model
`e(ic)`	number of iterations
`e(rc)`	return code
`e(converged)`	`1` if converged, `0` otherwise

Macros

`e(cmd)`	`biprobit`
`e(cmdline)`	command as typed
`e(depvar)`	names of dependent variables
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(clustvar)`	name of cluster variable
`e(offset1)`	offset for first equation
`e(offset2)`	offset for second equation
`e(chi2type)`	`Wald` or `LR`; type of model χ^2 test
`e(chi2_ct)`	`Wald` or `LR`; type of model χ^2 test corresponding to `e(chi2_c)`
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(opt)`	type of optimization
`e(which)`	`max` or `min`; whether optimizer is to perform maximization or minimization
`e(ml_method)`	type of `ml` method
`e(user)`	name of likelihood-evaluator program
`e(technique)`	maximization technique
`e(properties)`	`b V`
`d(predict)`	program used to implement `predict`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

biprobit is implemented as an ado-file.

The log likelihood, $\ln L$, is given by

$$\begin{aligned}
\xi_j^{\beta} &= x_j\beta + \text{offset}_j^{\beta} \\
\xi_j^{\gamma} &= z_j\gamma + \text{offset}_j^{\gamma} \\
q_{1j} &= \begin{cases} 1 & \text{if } y_{1j} \neq 0 \\ -1 & \text{otherwise} \end{cases} \\
q_{2j} &= \begin{cases} 1 & \text{if } y_{2j} \neq 0 \\ -1 & \text{otherwise} \end{cases} \\
\rho_j^{*} &= q_{1j}q_{2j}\rho \\
\ln L &= \sum_{j=1}^{n} w_j \ln\Phi_2\left(q_{1j}\xi_j^{\beta}, q_{2j}\xi_j^{\gamma}, \rho_j^{*}\right)
\end{aligned}$$

where $\Phi_2()$ is the cumulative bivariate normal distribution function (with mean $[\,0\ \ 0\,]'$) and w_j is an optional weight for observation j. This derivation assumes that

$$\begin{aligned}
y_{1j}^{*} &= x_j\beta + \epsilon_{1j} + \text{offset}_j^{\beta} \\
y_{2j}^{*} &= z_j\gamma + \epsilon_{2j} + \text{offset}_j^{\gamma} \\
E(\epsilon_1) &= E(\epsilon_2) = 0 \\
\text{Var}(\epsilon_1) &= \text{Var}(\epsilon_2) = 1 \\
\text{Cov}(\epsilon_1, \epsilon_2) &= \rho
\end{aligned}$$

where y_{1j}^{*} and y_{2j}^{*} are the unobserved latent variables; instead, we observe only $y_{ij} = 1$ if $y_{ij}^{*} > 0$ and $y_{ij} = 0$ otherwise (for $i = 1, 2$).

In the maximum likelihood estimation, ρ is not directly estimated, but atanh ρ is

$$\text{atanh}\,\rho = \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right)$$

From the form of the likelihood, if $\rho = 0$, then the log likelihood for the bivariate probit models is equal to the sum of the log likelihoods of the two univariate probit models. A likelihood-ratio test may therefore be performed by comparing the likelihood of the full bivariate model with the sum of the log likelihoods for the univariate probit models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`biprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

biprobit postestimation — Postestimation tools for biprobit

Description

The following postestimation commands are available after `biprobit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]

```

statistic	Description
Main	
p11	$\Phi_2(\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, \rho)$, predicted probability $\Pr(y_{1j}=1, y_{2j}=1)$; the default
p10	$\Phi_2(\mathbf{x}_j\mathbf{b}, -\mathbf{z}_j\mathbf{g}, -\rho)$, predicted probability $\Pr(y_{1j}=1, y_{2j}=0)$
p01	$\Phi_2(-\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, -\rho)$, predicted probability $\Pr(y_{1j}=0, y_{2j}=1)$
p00	$\Phi_2(-\mathbf{x}_j\mathbf{b}, -\mathbf{z}_j\mathbf{g}, \rho)$, predicted probability $\Pr(y_{1j}=0, y_{2j}=0)$
pmarg1	$\Phi(\mathbf{x}_j\mathbf{b})$, marginal success probability for equation 1
pmarg2	$\Phi(\mathbf{z}_j\mathbf{g})$, marginal success probability for equation 2
pcond1	$\Phi_2(\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, \rho)/\Phi(\mathbf{z}_j\mathbf{g})$, conditional probability of success for equation 1
pcond2	$\Phi_2(\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, \rho)/\Phi(\mathbf{x}_j\mathbf{b})$, conditional probability of success for equation 2
xb1	$\mathbf{x}_j\mathbf{b}$, linear prediction for equation 1
xb2	$\mathbf{z}_j\mathbf{g}$, linear prediction for equation 2
stdp1	standard error of the linear prediction for equation 1
stdp2	standard error of the linear prediction for equation 2

where $\Phi()$ is the standard normal-distribution function and $\Phi_2()$ is the bivariate standard normal-distribution function.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

p11, the default, calculates the bivariate predicted probability $\Pr(y_{1j}=1, y_{2j}=1)$.

p10 calculates the bivariate predicted probability $\Pr(y_{1j}=1, y_{2j}=0)$.

p01 calculates the bivariate predicted probability $\Pr(y_{1j}=0, y_{2j}=1)$.

p00 calculates the bivariate predicted probability $\Pr(y_{1j}=0, y_{2j}=0)$.

pmarg1 calculates the univariate (marginal) predicted probability of success $\Pr(y_{1j}=1)$.

pmarg2 calculates the univariate (marginal) predicted probability of success $\Pr(y_{2j}=1)$.

pcond1 calculates the conditional (on success in equation 2) predicted probability of success $\Pr(y_{1j}=1, y_{2j}=1)/\Pr(y_{2j}=1)$.

pcond2 calculates the conditional (on success in equation 1) predicted probability of success $\Pr(y_{1j}=1, y_{2j}=1)/\Pr(y_{1j}=1)$.

`xb1` calculates the probit linear prediction $\mathbf{x}_j\mathbf{b}$.

`xb2` calculates the probit linear prediction $\mathbf{z}_j\mathbf{g}$.

`stdp1` calculates the standard error of the linear prediction for equation 1.

`stdp2` calculates the standard error of the linear prediction for equation 2.

`nooffset` is relevant only if you specified `offset1(`*varname*`)` or `offset2(`*varname*`)` for `biprobit`. It modifies the calculations made by `predict` so that they ignore the offset variables; the linear predictions are treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_{1\text{j}}$ and $\mathbf{z}_j\boldsymbol{\gamma}$ rather than as $\mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_{2\text{j}}$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\mathbf{z}_j\boldsymbol{\gamma})$.

The third new variable will contain $\partial \ln L/\partial(\text{atanh}\,\rho)$.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

bitest — Binomial probability test

Syntax

Binomial probability test

`bitest` *varname*`==` $\#_p$ [*if*] [*in*] [*weight*] [`,` `detail`]

Immediate form of binomial probability test

`bitesti` $\#_N$ $\#_{\text{succ}}$ $\#_p$ [`,` `detail`]

`by` is allowed with `bitest`; see [D] **by**.
`fweights` are allowed with `bitest`; see [U] **11.1.6 weight**.

Menu

bitest

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Binomial probability test

bitesti

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Binomial probability test calculator

Description

`bitest` performs exact hypothesis tests for binomial random variables. The null hypothesis is that the probability of a success on a trial is $\#_p$. The total number of trials is the number of nonmissing values of *varname* (in `bitest`) or $\#_N$ (in `bitesti`). The number of observed successes is the number of 1s in *varname* (in `bitest`) or $\#_{\text{succ}}$ (in `bitesti`). *varname* must contain only 0s, 1s, and missing.

`bitesti` is the immediate form of `bitest`; see [U] **19 Immediate commands** for a general introduction to immediate commands.

Option

Advanced

`detail` shows the probability of the observed number of successes, k_{obs}; the probability of the number of successes on the opposite tail of the distribution that is used to compute the two-sided p-value, k_{opp}; and the probability of the point next to k_{opp}. This information can be safely ignored. See the technical note below for details.

Remarks

Remarks are presented under the following headings:

bitest
bitesti

bitest

▷ Example 1

We test 15 university students for high levels of one measure of visual quickness which, from other evidence, we believe is present in 30% of the nonuniversity population. Included in our data is `quick`, taking on the values 1 ("success") or 0 ("failure") depending on the outcome of the test.

```
. use http://www.stata-press.com/data/r12/quick
. bitest quick == 0.3
```

Variable	N	Observed k	Expected k	Assumed p	Observed p
quick	15	7	4.5	0.30000	0.46667

```
Pr(k >= 7)            = 0.131143  (one-sided test)
Pr(k <= 7)            = 0.949987  (one-sided test)
Pr(k <= 1 or k >= 7) = 0.166410  (two-sided test)
```

The first part of the output reveals that, assuming a true probability of success of 0.3, the expected number of successes is 4.5 and that we observed seven. Said differently, the assumed frequency under the null hypothesis H_0 is 0.3, and the observed frequency is 0.47.

The first line under the table is a one-sided test; it is the probability of observing seven or more successes conditional on $p = 0.3$. It is a test of $H_0: p = 0.3$ versus the alternative hypothesis $H_A: p > 0.3$. Said in English, the alternative hypothesis is that more than 30% of university students score at high levels on this test of visual quickness. The p-value for this hypothesis test is 0.13.

The second line under the table is a one-sided test of H_0 versus the opposite alternative hypothesis $H_A: p < 0.3$.

The third line is the two-sided test. It is a test of H_0 versus the alternative hypothesis $H_A: p \neq 0.3$.

◁

❑ Technical note

The p-value of a hypothesis test is the probability (calculated assuming H_0 is true) of observing any outcome as extreme or more extreme than the observed outcome, with extreme meaning in the direction of the alternative hypothesis. In example 1, the outcomes $k = 8, 9, \ldots, 15$ are clearly "more extreme" than the observed outcome $k_{obs} = 7$ when considering the alternative hypothesis $H_A: p \neq 0.3$. However, outcomes with only a few successes are also in the direction of this alternative hypothesis. For two-sided hypotheses, outcomes with k successes are considered "as extreme or more extreme" than the observed outcome k_{obs} if $\Pr(k) \leq \Pr(k_{obs})$. Here $\Pr(k = 0)$ and $\Pr(k = 1)$ are both less than $\Pr(k = 7)$, so they are included in the two-sided p-value.

The `detail` option allows you to see the probability (assuming that H_0 is true) of the observed successes ($k = 7$) and the probability of the boundary point ($k = 1$) of the opposite tail used for the two-sided p-value.

```
. bitest quick == 0.3, detail
    Variable |        N   Observed k   Expected k   Assumed p   Observed p
-------------+--------------------------------------------------------------
       quick |       15           7          4.5     0.30000      0.46667

  Pr(k >= 7)            = 0.131143  (one-sided test)
  Pr(k <= 7)            = 0.949987  (one-sided test)
  Pr(k <= 1 or k >= 7) = 0.166410  (two-sided test)

  Pr(k == 7)            = 0.081130  (observed)
  Pr(k == 2)            = 0.091560
  Pr(k == 1)            = 0.030520  (opposite extreme)
```

Also shown is the probability of the point next to the boundary point. This probability, namely, $\Pr(k = 2) = 0.092$, is certainly close to the probability of the observed outcome $\Pr(k = 7) = 0.081$, so some people might argue that $k = 2$ should be included in the two-sided p-value. Statisticians (at least some we know) would reply that the p-value is a precisely defined concept and that this is an arbitrary "fuzzification" of its definition. When you compute exact p-values according to the precise definition of a p-value, your type I error is never more than what you say it is—so no one can criticize you for being anticonservative. Including the point $k = 2$ is being overly conservative because it makes the p-value larger yet. But it is your choice; being overly conservative, at least in statistics, is always safe. Know that `bitest` and `bitesti` always keep to the precise definition of a p-value, so if you wish to include this extra point, you must do so by hand or by using the `r()` saved results; see *Saved results* below.

❑

bitesti

▷ Example 2

The binomial test is a function of two statistics and one parameter: N, the number of observations; k_{obs}, the number of observed successes; and p, the assumed probability of a success on a trial. For instance, in a city of $N = 2{,}500{,}000$, we observe $k_{\text{obs}} = 36$ cases of a particular disease when the population rate for the disease is $p = 0.00001$.

```
. bitesti 2500000 36 .00001
        N   Observed k   Expected k   Assumed p   Observed p
------------------------------------------------------------
  2500000          36           25     0.00001      0.00001

  Pr(k >= 36)            = 0.022458  (one-sided test)
  Pr(k <= 36)            = 0.985448  (one-sided test)
  Pr(k <= 14 or k >= 36) = 0.034859  (two-sided test)
```

◁

▷ Example 3

Boice and Monson (1977) present data on breast cancer cases and person-years of observations for women with tuberculosis who were repeatedly exposed to multiple x-ray fluoroscopies and for women with tuberculosis who were not. The data are

	Exposed	Not exposed	Total
Breast cancer	41	15	56
Person-years	28,010	19,017	47,027

We can thus test whether x-ray fluoroscopic examinations are associated with breast cancer; the assumed rate of exposure is $p = 28010/47027$.

```
. bitesti 56 41 28010/47027
        N   Observed k   Expected k   Assumed p   Observed p
------------------------------------------------------------
       56          41     33.35446       0.59562      0.73214

  Pr(k >= 41)            = 0.023830  (one-sided test)
  Pr(k <= 41)            = 0.988373  (one-sided test)
  Pr(k <= 25 or k >= 41) = 0.040852  (two-sided test)
```

◁

Saved results

`bitest` and `bitesti` save the following in `r()`:

Scalars

`r(N)`	number N of trials	`r(k_opp)`	opposite extreme k
`r(P_p)`	assumed probability p of success	`r(P_k)`	probability of observed k (`detail` only)
`r(k)`	observed number k of successes	`r(P_oppk)`	probability of opposite extreme k (`detail` only)
`r(p_l)`	lower one-sided p-value	`r(k_nopp)`	k next to opposite extreme (`detail` only)
`r(p_u)`	upper one-sided p-value	`r(P_noppk)`	probability of k next to opposite extreme (`detail` only)
`r(p)`	two-sided p-value		

Methods and formulas

`bitest` and `bitesti` are implemented as ado-files.

Let N, k_{obs}, and p be, respectively, the number of observations, the observed number of successes, and the assumed probability of success on a trial. The expected number of successes is Np, and the observed probability of success on a trial is k_{obs}/N.

`bitest` and `bitesti` compute exact p-values based on the binomial distribution. The upper one-sided p-value is

$$\Pr(k \geq k_{\text{obs}}) = \sum_{m=k_{\text{obs}}}^{N} \binom{N}{m} p^m (1-p)^{N-m}$$

The lower one-sided p-value is

$$\Pr(k \leq k_{\text{obs}}) = \sum_{m=0}^{k_{\text{obs}}} \binom{N}{m} p^m (1-p)^{N-m}$$

If $k_{\text{obs}} \geq Np$, the two-sided p-value is

$$\Pr(k \leq k_{\text{opp}} \text{ or } k \geq k_{\text{obs}})$$

where k_{opp} is the largest number $\leq Np$ such that $\Pr(k = k_{\text{opp}}) \leq \Pr(k = k_{\text{obs}})$. If $k_{\text{obs}} < Np$, the two-sided p-value is

$$\Pr(k \leq k_{\text{obs}} \text{ or } k \geq k_{\text{opp}})$$

where k_{opp} is the smallest number $\geq Np$ such that $\Pr(k = k_{\text{opp}}) \leq \Pr(k = k_{\text{obs}})$.

Title

bootstrap — Bootstrap sampling and estimation

Syntax

`bootstrap` *exp_list* [, *options eform_option*] : *command*

options	Description
Main	
`reps(#)`	perform # bootstrap replications; default is `reps(50)`
Options	
`strata(`*varlist*`)`	variables identifying strata
`size(#)`	draw samples of size #; default is `_N`
`cluster(`*varlist*`)`	variables identifying resampling clusters
`idcluster(`*newvar*`)`	create new cluster ID variable
`saving(`*filename*`, ...)`	save results to *filename*; save statistics in double precision; save results to *filename* every # replications
`bca`	compute acceleration for BC_a confidence intervals
`mse`	use MSE formula for variance estimation
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`notable`	suppress table of results
`noheader`	suppress table header
`nolegend`	suppress table legend
`verbose`	display the full table legend
`nodots`	suppress replication dots
`noisily`	display any output from *command*
`trace`	trace *command*
`title(`*text*`)`	use *text* as title for bootstrap results
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
eform_option	display coefficient table in exponentiated form
Advanced	
`nodrop`	do not drop observations
`nowarn`	do not warn when `e(sample)` is not set
`force`	do not check for *weights* or `svy` commands; seldom used
`reject(`*exp*`)`	identify invalid results
`seed(#)`	set random-number seed to #
`group(`*varname*`)`	ID variable for groups within `cluster()`
`jackknifeopts(`*jkopts*`)`	options for `jackknife`; see [R] **jackknife**
`coeflegend`	display legend instead of statistics

weights are not allowed in *command*.

`group()`, `jackknifeopts()`, and `coeflegend` do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

exp_list contains	(*name*: *elist*)
	elist
	eexp
elist contains	*newvar* = (*exp*)
	(*exp*)
eexp is	*specname*
	[*eqno*]*specname*
specname is	_b
	_b[]
	_se
	_se[]
eqno is	##
	name

exp is a standard Stata expression; see [U] **13 Functions and expressions**.

Distinguish between `[]`, which are to be typed, and [ ], which indicate optional arguments.

Menu

Statistics > Resampling > Bootstrap estimation

Description

`bootstrap` performs bootstrap estimation. Typing

```
. bootstrap exp_list, reps(#): command
```

executes *command* multiple times, bootstrapping the statistics in *exp_list* by resampling observations (with replacement) from the data in memory # times. This method is commonly referred to as the nonparametric bootstrap.

command defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `bootstrap`, as long as they follow standard Stata syntax; see [U] **11 Language syntax**. If the `bca` option is supplied, *command* must also work with `jackknife`; see [R] **jackknife**. The `by` prefix may not be part of *command*.

exp_list specifies the statistics to be collected from the execution of *command*. If *command* changes the contents in `e(b)`, *exp_list* is optional and defaults to `_b`.

Because bootstrapping is a random process, if you want to be able to reproduce results, set the random-number seed by specifying the `seed(#)` option or by typing

```
. set seed #
```

where # is a seed of your choosing, before running `bootstrap`; see [R] **set seed**.

Many estimation commands allow the vce(bootstrap) option. For those commands, we recommend using vce(bootstrap) over bootstrap because the estimation command already handles clustering and other model-specific details for you. The bootstrap prefix command is intended for use with nonestimation commands, such as summarize, user-written commands, or functions of coefficients.

bs and bstrap are synonyms for bootstrap.

Options

Main

reps(#) specifies the number of bootstrap replications to be performed. The default is 50. A total of 50–200 replications are generally adequate for estimates of standard error and thus are adequate for normal-approximation confidence intervals; see Mooney and Duval (1993, 11). Estimates of confidence intervals using the percentile or bias-corrected methods typically require 1,000 or more replications.

Options

strata(*varlist*) specifies the variables that identify strata. If this option is specified, bootstrap samples are taken independently within each stratum.

size(#) specifies the size of the samples to be drawn. The default is _N, meaning to draw samples of the same size as the data. If specified, # must be less than or equal to the number of observations within strata().

If cluster() is specified, the default size is the number of clusters in the original dataset. For unbalanced clusters, resulting sample sizes will differ from replication to replication. For cluster sampling, # must be less than or equal to the number of clusters within strata().

cluster(*varlist*) specifies the variables that identify resampling clusters. If this option is specified, the sample drawn during each replication is a bootstrap sample of clusters.

idcluster(*newvar*) creates a new variable containing a unique identifier for each resampled cluster. This option requires that cluster() also be specified.

saving(*filename* [, *suboptions*]) creates a Stata data file (.dta file) consisting of (for each statistic in *exp_list*) a variable containing the replicates.

double specifies that the results for each replication be stored as doubles, meaning 8-byte reals. By default, they are stored as floats, meaning 4-byte reals. This option may be used without the saving() option to compute the variance estimates by using double precision.

every(#) specifies that results be written to disk every #th replication. every() should be specified only in conjunction with saving() when *command* takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer. See [P] **postfile**.

replace specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

bca specifies that bootstrap estimate the acceleration of each statistic in *exp_list*. This estimate is used to construct BC_a confidence intervals. Type estat bootstrap, bca to display the BC_a confidence interval generated by the bootstrap command.

mse specifies that bootstrap compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, bootstrap computes the variance by using deviations from the average of the replicates.

Reporting

`level(#)`; see [R] **estimation options**.

`notable` suppresses the display of the table of results.

`noheader` suppresses the display of the table header. This option implies `nolegend`. This option may also be specified when replaying estimation results.

`nolegend` suppresses the display of the table legend. This option may also be specified when replaying estimation results.

`verbose` specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed. This option may also be specified when replaying estimation results.

`nodots` suppresses display of the replication dots. By default, one dot character is displayed for each successful replication. A red 'x' is displayed if *command* returns an error or if one of the values in *exp_list* is missing.

`noisily` specifies that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(`*text*`)` specifies a title to be displayed above the table of bootstrap results. The default title is the title saved in `e(title)` by an estimation command, or if `e(title)` is not filled in, `Bootstrap results` is used. `title()` may also be specified when replaying estimation results.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

eform_option causes the coefficient table to be displayed in exponentiated form; see [R] ***eform_option***.

command determines which of the following are allowed (`eform(`*string*`)` and `eform` are always allowed):

eform_option	Description
`eform(`*string*`)`	use *string* for the column title
`eform`	exponentiated coefficient, *string* is `exp(b)`
`hr`	hazard ratio, *string* is `Haz. Ratio`
`shr`	subhazard ratio, *string* is `SHR`
`irr`	incidence-rate ratio, *string* is `IRR`
`or`	odds ratio, *string* is `Odds Ratio`
`rrr`	relative-risk ratio, *string* is `RRR`

Advanced

`nodrop` prevents observations outside `e(sample)` and the `if` and `in` qualifiers from being dropped before the data are resampled.

`nowarn` suppresses the display of a warning message when *command* does not set `e(sample)`.

`force` suppresses the restriction that *command* not specify weights or be a `svy` command. This is a rarely used option. Use it only if you know what you are doing.

`reject(`*exp*`)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

`seed(#)` sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling `bootstrap`:

```
. set seed #
```

The following options are available with `bootstrap` but are not shown in the dialog box:

`group(`*varname*`)` re-creates *varname* containing a unique identifier for each group across the resampled clusters. This option requires that `idcluster()` also be specified.

This option is useful for maintaining unique group identifiers when sampling clusters with replacement. Suppose that cluster 1 contains 3 groups. If the `idcluster(newclid)` option is specified and cluster 1 is sampled multiple times, `newclid` uniquely identifies each copy of cluster 1. If `group(newgroupid)` is also specified, `newgroupid` uniquely identifies each copy of each group.

`jackknifeopts(`*jkopts*`)` identifies options that are to be passed to `jackknife` when it computes the acceleration values for the BC$_a$ confidence intervals; see [R] **jackknife**. This option requires the `bca` option and is mostly used for passing the `eclass`, `rclass`, or `n(#)` option to `jackknife`.

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Regression coefficients
Expressions
Combining bootstrap datasets
A note about macros
Achieved significance level
Bootstrapping a ratio
Warning messages and e(sample)
Bootstrapping statistics from data with a complex structure

Introduction

With few assumptions, bootstrapping provides a way of estimating standard errors and other measures of statistical precision (Efron 1979; Efron and Stein 1981; Efron 1982; Efron and Tibshirani 1986; Efron and Tibshirani 1993; also see Davison and Hinkley [1997]; Guan [2003]; Mooney and Duval [1993]; Poi [2004]; and Stine [1990]). It provides a way to obtain such measures when no formula is otherwise available or when available formulas make inappropriate assumptions. Cameron and Trivedi (2010, chap. 13) discuss many bootstrapping topics and demonstrate how to do them in Stata.

To illustrate bootstrapping, suppose that you have a dataset containing N observations and an estimator that, when applied to the data, produces certain statistics. You draw, with replacement, N observations from the N-observation dataset. In this random drawing, some of the original observations will appear once, some more than once, and some not at all. Using the resampled dataset, you apply

the estimator and collect the statistics. This process is repeated many times; each time, a new random sample is drawn and the statistics are recalculated.

This process builds a dataset of replicated statistics. From these data, you can calculate the standard error by using the standard formula for the sample standard deviation

$$\widehat{\text{se}} = \left\{ \frac{1}{k-1} \sum (\widehat{\theta}_i - \overline{\theta})^2 \right\}^{1/2}$$

where $\widehat{\theta}_i$ is the statistic calculated using the ith bootstrap sample and k is the number of replications. This formula gives an estimate of the standard error of the statistic, according to Hall and Wilson (1991). Although the average, $\overline{\theta}$, of the bootstrapped estimates is used in calculating the standard deviation, it is not used as the estimated value of the statistic itself. Instead, the original observed value of the statistic, $\widehat{\theta}$, is used, meaning the value of the statistic computed using the original N observations.

You might think that $\overline{\theta}$ is a better estimate of the parameter than $\widehat{\theta}$, but it is not. If the statistic is biased, bootstrapping exaggerates the bias. In fact, the bias can be estimated as $\overline{\theta} - \widehat{\theta}$ (Efron 1982, 33). Knowing this, you might be tempted to subtract this estimate of bias from $\widehat{\theta}$ to produce an unbiased statistic. The bootstrap bias estimate has an indeterminate amount of random error, so this unbiased estimator may have greater mean squared error than the biased estimator (Mooney and Duval 1993; Hinkley 1978). Thus $\widehat{\theta}$ is the best point estimate of the statistic.

The logic behind the bootstrap is that all measures of precision come from a statistic's sampling distribution. When the statistic is estimated on a sample of size N from some population, the sampling distribution tells you the relative frequencies of the values of the statistic. The sampling distribution, in turn, is determined by the distribution of the population and the formula used to estimate the statistic.

Sometimes the sampling distribution can be derived analytically. For instance, if the underlying population is distributed normally and you calculate means, the sampling distribution for the mean is also normal but has a smaller variance than that of the population. In other cases, deriving the sampling distribution is difficult, as when means are calculated from nonnormal populations. Sometimes, as in the case of means, it is not too difficult to derive the sampling distribution as the sample size goes to infinity ($N \rightarrow \infty$). However, such asymptotic distributions may not perform well when applied to finite samples.

If you knew the population distribution, you could obtain the sampling distribution by simulation: you could draw random samples of size N, calculate the statistic, and make a tally. Bootstrapping does precisely this, but it uses the observed distribution of the sample in place of the true population distribution. Thus the bootstrap procedure hinges on the assumption that the observed distribution is a good estimate of the underlying population distribution. In return, the bootstrap produces an estimate, called the bootstrap distribution, of the sampling distribution. From this, you can estimate the standard error of the statistic, produce confidence intervals, etc.

The accuracy with which the bootstrap distribution estimates the sampling distribution depends on the number of observations in the original sample and the number of replications in the bootstrap. A crudely estimated sampling distribution is adequate if you are only going to extract, say, a standard error. A better estimate is needed if you want to use the 2.5th and 97.5th percentiles of the distribution to produce a 95% confidence interval. To extract many features simultaneously about the distribution, an even better estimate is needed. Generally, replications on the order of 1,000 produce very good estimates, but only 50–200 replications are needed for estimates of standard errors. See Poi (2004) for a method to choose the number of bootstrap replications.

Regression coefficients

▷ Example 1

Let's say that we wish to compute bootstrap estimates for the standard errors of the coefficients from the following regression:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight gear foreign
```

Source	SS	df	MS	Number of obs =	74
Model	1629.67805	3	543.226016	F(3, 70) =	46.73
Residual	813.781411	70	11.6254487	Prob > F =	0.0000
				R-squared =	0.6670
				Adj R-squared =	0.6527
Total	2443.45946	73	33.4720474	Root MSE =	3.4096

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.006139	.0007949	-7.72	0.000	-.0077245	-.0045536
gear_ratio	1.457113	1.541286	0.95	0.348	-1.616884	4.53111
foreign	-2.221682	1.234961	-1.80	0.076	-4.684735	.2413715
_cons	36.10135	6.285984	5.74	0.000	23.56435	48.63835

To run the bootstrap, we simply prefix the above regression command with the `bootstrap` command (specifying its options before the colon separator). We must set the random-number seed before calling `bootstrap`.

```
. bootstrap, reps(100) seed(1): regress mpg weight gear foreign
(running regress on estimation sample)
Bootstrap replications (100)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................   50
..................................................   100
```

Linear regression

Number of obs	= 74
Replications	= 100
Wald chi2(3)	= 111.96
Prob > chi2	= 0.0000
R-squared	= 0.6670
Adj R-squared	= 0.6527
Root MSE	= 3.4096

mpg	Observed Coef.	Bootstrap Std. Err.	z	P>|z|	Normal-based [95% Conf.	Interval]
weight	-.006139	.0006498	-9.45	0.000	-.0074127	-.0048654
gear_ratio	1.457113	1.297786	1.12	0.262	-1.086501	4.000727
foreign	-2.221682	1.162728	-1.91	0.056	-4.500587	.0572236
_cons	36.10135	4.71779	7.65	0.000	26.85465	45.34805

The displayed confidence interval is based on the assumption that the sampling (and hence bootstrap) distribution is approximately normal (see *Methods and formulas* below). Because this confidence interval is based on the standard error, it is a reasonable estimate if normality is approximately true, even for a few replications. Other types of confidence intervals are available after `bootstrap`; see [R] **bootstrap postestimation**.

We could instead supply names to our expressions when we run bootstrap. For example,

```
. bootstrap diff=(_b[weight]-_b[gear]): regress mpg weight gear foreign
```

would bootstrap a statistic, named diff, equal to the difference between the coefficients on weight and gear_ratio.

◁

Expressions

▷ Example 2

When we use bootstrap, the list of statistics can contain complex expressions, as long as each expression is enclosed in parentheses. For example, to bootstrap the range of a variable x, we could type

```
. bootstrap range=(r(max)-r(min)), reps(1000): summarize x
```

Of course, we could also bootstrap the minimum and maximum and later compute the range.

```
. bootstrap max=r(max) min=r(min), reps(1000) saving(mybs): summarize x
. use mybs, clear
(bootstrap: summarize)
. generate range = max - min
. bstat range, stat(19.5637501)
```

The difference between the maximum and minimum of x in the sample is 19.5637501.

The stat() option to bstat specifies the observed value of the statistic (range) to be summarized. This option is useful when, as shown above, the statistic of ultimate interest is not specified directly to bootstrap but instead is calculated by other means.

Here the observed values of r(max) and r(min) are saved as characteristics of the dataset created by bootstrap and are thus available for retrieval by bstat; see [R] **bstat**. The observed range, however, is unknown to bstat, so it must be specified.

◁

Combining bootstrap datasets

You can combine two datasets from separate runs of bootstrap by using append (see [D] **append**) and then get the bootstrap statistics for the combined datasets by running bstat. The runs must have been performed independently (having different starting random-number seeds), and the original dataset, command, and bootstrap statistics must have been all the same.

A note about macros

In the previous example, we executed the command

```
. bootstrap max=r(max) min=r(min), reps(1000) saving(mybs): summarize x
```

We did not enclose `r(max)` and `r(min)` in single quotes, as we would in most other contexts, because it would not produce what was intended:

```
. bootstrap 'r(max)' 'r(min)', reps(1000) saving(mybs): summarize x
```

To understand why, note that `'r(max)'`, like any reference to a local macro, will evaluate to a literal string containing the contents of `r(max)` *before* `bootstrap` is even executed. Typing the command above would appear to Stata as if we had typed

```
. bootstrap 14.5441234 33.4393293, reps(1000) saving(mybs): summarize x
```

Even worse, the current contents of `r(min)` and `r(max)` could be empty, producing an even more confusing result. To avoid this outcome, refer to statistics by name (for example, `r(max)`) and not by value (for example, `'r(max)'`).

Achieved significance level

▷ Example 3

Suppose that we wish to estimate the *achieved significance level* (ASL) of a test statistic by using the bootstrap. ASL is another name for p-value. An example is

$$\text{ASL} = \Pr\left(\widehat{\theta}^* \geq \widehat{\theta} | H_0\right)$$

for an upper-tailed, alternative hypothesis, where H_0 denotes the null hypothesis, $\widehat{\theta}$ is the observed value of the test statistic, and $\widehat{\theta}^*$ is the random variable corresponding to the test statistic, assuming that H_0 is true.

Here we will compare the mean miles per gallon (`mpg`) between foreign and domestic cars by using the two-sample t test with unequal variances. The following results indicate the p-value to be `0.0034` for the two-sided test using Satterthwaite's approximation. Thus assuming that mean `mpg` is the same for foreign and domestic cars, we would expect to observe a t statistic more extreme (in absolute value) than `3.1797` in about 0.3% of all possible samples of the type that we observed. Thus we have evidence to reject the null hypothesis that the means are equal.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ttest mpg, by(foreign) unequal
Two-sample t test with unequal variances
```

Group	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf.	Interval]
Domestic	52	19.82692	.657777	4.743297	18.50638	21.14747
Foreign	22	24.77273	1.40951	6.611187	21.84149	27.70396
combined	74	21.2973	.6725511	5.785503	19.9569	22.63769
diff		-4.945804	1.555438		-8.120053	-1.771556

```
    diff = mean(Domestic) - mean(Foreign)                         t =  -3.1797
Ho: diff = 0                     Satterthwaite's degrees of freedom =  30.5463
    Ha: diff < 0                 Ha: diff != 0                 Ha: diff > 0
 Pr(T < t) = 0.0017         Pr(|T| > |t|) = 0.0034          Pr(T > t) = 0.9983
```

We also place the value of the test statistic in a scalar for later use.

```
. scalar tobs = r(t)
```

Efron and Tibshirani (1993, 224) describe an alternative to Satterthwaite's approximation that estimates the ASL by bootstrapping the statistic from the test of equal means. Their idea is to recenter the two samples to the combined sample mean so that the data now conform to the null hypothesis but that the variances within the samples remain unchanged.

```
. summarize mpg, meanonly
. scalar omean = r(mean)
. summarize mpg if foreign==0, meanonly
. replace mpg = mpg - r(mean) + scalar(omean) if foreign==0
mpg was int now float
(52 real changes made)
. summarize mpg if foreign==1, meanonly
. replace mpg = mpg - r(mean) + scalar(omean) if foreign==1
(22 real changes made)
. sort foreign
. by foreign: summarize mpg
```

```
-> foreign = Domestic
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
         mpg |         52     21.2973    4.743297   13.47037   35.47038

-> foreign = Foreign
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
         mpg |         22     21.2973    6.611187   10.52457   37.52457
```

Each sample (foreign and domestic) is a stratum, so the bootstrapped samples must have the same number of foreign and domestic cars as the original dataset. This requirement is facilitated by the `strata()` option to `bootstrap`. By typing the following, we bootstrap the test statistic using the modified dataset and save the values in `bsauto2.dta`:

```
. keep mpg foreign
. set seed 1
. bootstrap t=r(t), rep(1000) strata(foreign) saving(bsauto2) nodots: ttest mpg,
> by(foreign) unequal
Warning:  Because ttest is not an estimation command or does not set
          e(sample), bootstrap has no way to determine which observations are
          used in calculating the statistics and so assumes that all
          observations are used.  This means that no observations will be
          excluded from the resampling because of missing values or other
          reasons.

          If the assumption is not true, press Break, save the data, and drop
          the observations that are to be excluded.  Be sure that the dataset
          in memory contains only the relevant data.

Bootstrap results
Number of strata   =         2                  Number of obs      =        74
                                                 Replications       =      1000

      command:  ttest mpg, by(foreign) unequal
            t:  r(t)

------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
           t |   1.75e-07   1.036437     0.00   1.000    -2.031379    2.031379
------------------------------------------------------------------------------
```

We can use the data in `bsauto2.dta` to estimate ASL via the fraction of bootstrap test statistics that are more extreme than `3.1797`.

```
. use bsauto2, clear
(bootstrap: ttest)
. generate indicator = abs(t)>=abs(scalar(tobs))
. summarize indicator, meanonly
. display "ASLboot = " r(mean)
ASLboot = .005
```

The result is $\text{ASL}_{\text{boot}} = 0.005$. Assuming that the mean `mpg` is the same between foreign and domestic cars, we would expect to observe a t statistic more extreme (in absolute value) than `3.1797` in about 0.5% of all possible samples of the type we observed. This finding is still strong evidence to reject the hypothesis that the means are equal.

◁

Bootstrapping a ratio

▷ Example 4

Suppose that we wish to produce a bootstrap estimate of the ratio of two means. Because `summarize` saves results for only one variable, we must call `summarize` twice to compute the means. Actually, we could use `collapse` to compute the means in one call, but calling `summarize` twice is much faster. Thus we will have to write a small program that will return the results we want.

We write the program below and save it to a file called `ratio.ado` (see [U] **17 Ado-files**). Our program takes two variable names as input and saves them in the `local` macros `y` (first variable) and `x` (second variable). It then computes one statistic: the mean of `'y'` divided by the mean of `'x'`. This value is returned as a scalar in `r(ratio)`. `ratio` also returns the ratio of the number of observations used to the mean for each variable.

```
program myratio, rclass
        version 12
        args y x
        confirm var 'y'
        confirm var 'x'
        tempname ymean yn
        summarize 'y', meanonly
        scalar 'ymean' = r(mean)
        return scalar n_'y' = r(N)
        summarize 'x', meanonly
        return scalar n_'x' = r(N)
        return scalar ratio = 'ymean'/r(mean)
end
```

Remember to test any newly written commands before using them with `bootstrap`.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. summarize price
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
       price |         74    6165.257    2949.496       3291      15906
. scalar mean1=r(mean)
. summarize weight
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
      weight |         74    3019.459    777.1936       1760       4840
. scalar mean2=r(mean)
. di scalar(mean1)/scalar(mean2)
2.0418412
. myratio price weight
. return list
scalars:
             r(ratio) =  2.041841210168278
          r(n_weight) =  74
           r(n_price) =  74
```

The results of running bootstrap on our program are

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. set seed 1
. bootstrap ratio=r(ratio), reps(1000) nowarn nodots: myratio price weight
Bootstrap results                                 Number of obs      =        74
                                                  Replications       =      1000
      command:  myratio price weight
        ratio:  r(ratio)
------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       ratio |   2.041841   .0942932    21.65   0.000      1.85703    2.226652
------------------------------------------------------------------------------
```

As mentioned previously, we should specify the saving() option if we wish to save the bootstrap dataset.

◁

Warning messages and e(sample)

bootstrap is not meant to be used with weighted calculations. bootstrap determines the presence of weights by parsing the prefixed command with standard syntax. However, commands like stcox and streg require that weights be specified in stset, and some user commands may allow weights to be specified by using an option instead of the standard syntax. Both cases pose a problem for bootstrap because it cannot determine the presence of weights under these circumstances. In these cases, we can only assume that you know what you are doing.

bootstrap does not know which variables of the dataset in memory matter to the calculation at hand. You can speed their execution by dropping unnecessary variables because, otherwise, they are included in each bootstrap sample.

You should thus drop observations with missing values. Leaving in missing values causes no problem in one sense because all Stata commands deal with missing values gracefully. It does, however, cause a statistical problem. Bootstrap sampling is defined as drawing, with replacement, samples of size N from a set of N observations. bootstrap determines N by counting the number of observations in memory, not counting the number of nonmissing values on the relevant variables. The result is that too many observations are resampled; the resulting bootstrap samples, because they are drawn from a population with missing values, are of unequal sizes.

If the number of missing values relative to the sample size is small, this will make little difference. If you have many missing values, however, you should first drop the observations that contain them.

▷ Example 5

To illustrate, we use the previous example but replace some of the values of price with missing values. The number of values of price used to compute the mean for each bootstrap is not constant. This is the purpose of the Warning message.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. replace price = . if inlist(_n,1,3,5,7)
(4 real changes made, 4 to missing)
. set seed 1
```

```
. bootstrap ratio=r(ratio) np=r(n_price) nw=r(n_weight), reps(100) nodots:
> myratio price weight
Warning:  Because myratio is not an estimation command or does not set
          e(sample), bootstrap has no way to determine which observations are
          used in calculating the statistics and so assumes that all
          observations are used.  This means that no observations will be
          excluded from the resampling because of missing values or other
          reasons.

          If the assumption is not true, press Break, save the data, and drop
          the observations that are to be excluded.  Be sure that the dataset
          in memory contains only the relevant data.

Bootstrap results                                 Number of obs      =        74
                                                  Replications       =       100

      command:  myratio price weight
        ratio:  r(ratio)
           np:  r(n_price)
           nw:  r(n_weight)

```

Bootstrapping statistics from data with a complex structure

Here we describe how to bootstrap statistics from data with a complex structure, for example, longitudinal or panel data, or matched data. `bootstrap`, however, is not designed to work with complex survey data. It is important to include all necessary information about the structure of the data in the `bootstrap` syntax to obtain correct bootstrap estimates for standard errors and confidence intervals.

`bootstrap` offers several options identifying the specifics of the data. These options are `strata()`, `cluster()`, `idcluster()`, and `group()`. The usage of `strata()` was described in example 3 above. Below we demonstrate several examples that require specifying the other three options.

▷ Example 6

Suppose that the `auto` data in example 1 above are clustered by `rep78`. We want to obtain bootstrap estimates for the standard errors of the difference between the coefficients on `weight` and `gear_ratio`, taking into account clustering.

We supply the `cluster(rep78)` option to `bootstrap` to request resampling from clusters rather than from observations in the dataset.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. keep if rep78 < .
(5 observations deleted)
. bootstrap diff=(_b[weight]-_b[gear]), seed(1) cluster(rep78): regress mpg weight
> gear foreign
(running regress on estimation sample)
Bootstrap replications (50)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
Linear regression                               Number of obs      =        69
                                                Replications       =        50
      command:  regress mpg weight gear foreign
         diff:  _b[weight]-_b[gear]
                                    (Replications based on 5 clusters in rep78)
------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
        diff |  -1.910396   1.876778    -1.02   0.309    -5.588812    1.768021
------------------------------------------------------------------------------
```

We drop missing values in `rep78` before issuing the command because `bootstrap` does not allow missing values in `cluster()`. See the section above about using `bootstrap` when variables contain missing values.

We can also obtain these same results by using the following syntax:

```
. bootstrap diff=(_b[weight]-_b[gear]), seed(1): regress mpg weight gear foreign,
> vce(cluster rep78)
```

When only clustered information is provided to the command, `bootstrap` can pick up the `vce(cluster` *clustvar*`)` option from the main command and use it to resample from clusters.

◁

▷ Example 7

Suppose now that we have matched data and want to use `bootstrap` to obtain estimates of the standard errors of the exponentiated difference between two coefficients (or, equivalently, the ratio of two odds ratios) estimated by `clogit`. Consider the example of matched case–control data on birthweight of infants described in example 2 of [R] **clogit**.

The infants are paired by being matched on mother's age. All groups, defined by the `pairid` variable, have 1:2 matching. `clogit` requires that the matching information, `pairid`, be supplied to the `group()` (or, equivalently, `strata()`) option to be used in computing the parameter estimates. Because the data are matched, we need to resample from groups rather than from the whole dataset. However, simply supplying the grouping variable `pairid` in `cluster()` is not enough with `bootstrap`, as it is with clustered data.

```
. use http://www.stata-press.com/data/r12/lowbirth2, clear
(Applied Logistic Regression, Hosmer & Lemeshow)
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), seed(1) cluster(pairid): clogit low lwt
> smoke ptd ht ui i.race, group(pairid)
(running clogit on estimation sample)

Bootstrap replications (50)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50

Bootstrap results                               Number of obs      =       112
                                                Replications       =        50

      command:  clogit low lwt smoke ptd ht ui i.race, group(pairid)
        ratio:  exp(_b[smoke]-_b[ptd])

                                 (Replications based on 56 clusters in pairid)
------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       ratio |   .6654095   17.71791     0.04   0.970    -34.06106    35.39187
------------------------------------------------------------------------------
```

For the syntax above, imagine that the first pair was sampled twice during a replication. Then the bootstrap sample has four subjects with `pairid` equal to one, which clearly violates the original 1:2 matching design. As a result, the estimates of the coefficients obtained from this bootstrap sample will be incorrect.

Therefore, in addition to resampling from groups, we need to ensure that resampled groups are uniquely identified in each of the bootstrap samples. The `idcluster(`*newcluster*`)` option is designed for this. It requests that at each replication `bootstrap` create the new variable, *newcluster*, containing unique identifiers for all resampled groups. Thus, to make sure that the correct matching is preserved during each replication, we need to specify the grouping variable in `cluster()`, supply a variable name to `idcluster()`, and use this variable as the grouping variable with `clogit`, as we demonstrate below.

```
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), seed(1) cluster(pairid)
> idcluster(newpairid): clogit low lwt smoke ptd ht ui i.race, group(newpairid)
(running clogit on estimation sample)

Bootstrap replications (50)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50

Bootstrap results                               Number of obs      =       112
                                                Replications       =        50

      command:  clogit low lwt smoke ptd ht ui i.race, group(newpairid)
        ratio:  exp(_b[smoke]-_b[ptd])

                                 (Replications based on 56 clusters in pairid)
------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       ratio |   .6654095   7.919441     0.08   0.933    -14.85641    16.18723
------------------------------------------------------------------------------
```

Note the difference between the estimates of the bootstrap standard error for the two specifications of the `bootstrap` syntax.

◁

❑ Technical note

Similarly, when you have panel (longitudinal) data, all resampled panels must be unique in each of the bootstrap samples to obtain correct bootstrap estimates of statistics. Therefore, both `cluster(`*panelvar*`)` and `idcluster(`*newpanelvar*`)` must be specified with `bootstrap`, and `i(`*newpanelvar*`)` must be used with the main command. Moreover, you must clear the current `xtset` settings by typing `xtset, clear` before calling `bootstrap`.

❑

▷ Example 8

Continuing with our birthweight data, suppose that we have more information about doctors supervising women's pregnancies. We believe that the data on the pairs of infants from the same doctor may be correlated and want to adjust standard errors for possible correlation among the pairs. `clogit` offers the `vce(cluster` *clustvar*`)` option to do this.

Let's add a cluster variable to our dataset. One thing to keep in mind is that to use `vce(cluster` *clustvar*`)`, groups in `group()` must be nested within clusters.

```
. use http://www.stata-press.com/data/r12/lowbirth2, clear
(Applied Logistic Regression, Hosmer & Lemeshow)
. set seed 12345
. by pairid, sort: egen byte doctor = total(int(2*runiform()+1)*(_n == 1))
. clogit low lwt smoke ptd ht ui i.race, group(pairid) vce(cluster doctor)

```

To obtain correct bootstrap standard errors of the exponentiated difference between the two coefficients in this example, we need to make sure that both resampled clusters and groups within resampled clusters are unique in each of the bootstrap samples. To achieve this, `bootstrap` needs the information about clusters in `cluster()`, the variable name of the new identifier for clusters in `idcluster()`, and the information about groups in `group()`. We demonstrate the corresponding syntax of `bootstrap` below.

```
. bootstrap ratio=exp(_b[smoke]-_b[ptd]), seed(1) cluster(doctor)
> idcluster(uidoctor) group(pairid): clogit low lwt smoke ptd ht ui i.race,
> group(pairid)
(running clogit on estimation sample)

Bootstrap replications (50)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50

Bootstrap results                               Number of obs      =       112
                                                Replications       =        50

      command:  clogit low lwt smoke ptd ht ui i.race, group(pairid)
        ratio:  exp(_b[smoke]-_b[ptd])

                                  (Replications based on 2 clusters in doctor)
------------------------------------------------------------------------------
             |   Observed   Bootstrap                         Normal-based
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       ratio |   .6654095   .3156251     2.11   0.035     .0467956    1.284023
------------------------------------------------------------------------------
```

In the above syntax, although we specify `group(pairid)` with `clogit`, it is not the group identifiers of the original `pairid` variable that are used to compute parameter estimates from bootstrap samples. The way `bootstrap` works is that, at each replication, the clusters defined by `doctor` are resampled and the new variable, `uidoctor`, uniquely identifying resampled clusters is created. After that, another new variable uniquely identifying the (`uidoctor`, `group`) combination is created and renamed to have the same name as the grouping variable, `pairid`. This newly defined grouping variable is then used by `clogit` to obtain the parameter estimates from this bootstrap sample of clusters. After all replications are performed, the original values of the grouping variable are restored.

◁

❑ Technical note

The same logic must be used when running `bootstrap` with commands designed for panel (longitudinal) data that allow specifying the `cluster(`*clustervar*`)` option. To ensure that the combination of (*clustervar*, *panelvar*) values are unique in each of the bootstrap samples, `cluster(`*clustervar*`)`, `idcluster(`*newclustervar*`)`, and `group(`*panelvar*`)` must be specified with `bootstrap`, and `i(`*panelvar*`)` must be used with the main command.

❑

Bradley Efron was born in 1938 in Minnesota and studied mathematics and statistics at Caltech and Stanford; he has lived in northern California since 1960. He has worked on empirical Bayes, survival analysis, exponential families, bootstrap and jackknife methods, and confidence intervals, in conjunction with applied work in biostatistics, astronomy, and physics.

Saved results

bootstrap saves the following in e():

Scalars

e(N)	sample size
e(N_reps)	number of complete replications
e(N_misreps)	number of incomplete replications
e(N_strata)	number of strata
e(N_clust)	number of clusters
e(k_eq)	number of equations in e(b)
e(k_exp)	number of standard expressions
e(k_eexp)	number of extended expressions (i.e., _b)
e(k_extra)	number of extra equations beyond the original ones from e(b)
e(level)	confidence level for bootstrap CIs
e(bs_version)	version for bootstrap results
e(rank)	rank of e(V)

Macros

e(cmdname)	command name from *command*
e(cmd)	same as e(cmdname) or bootstrap
e(command)	*command*
e(cmdline)	command as typed
e(prefix)	bootstrap
e(title)	title in estimation output
e(strata)	strata variables
e(cluster)	cluster variables
e(seed)	initial random-number seed
e(size)	from the size(#) option
e(exp#)	expression for the #th statistic
e(mse)	mse, if specified
e(vce)	bootstrap
e(vcetype)	title used to label Std. Err.
e(properties)	b V

Matrices

e(b)	observed statistics
e(b_bs)	bootstrap estimates
e(reps)	number of nonmissing results
e(bias)	estimated biases
e(se)	estimated standard errors
e(z0)	median biases
e(accel)	estimated accelerations
e(ci_normal)	normal-approximation CIs
e(ci_percentile)	percentile CIs
e(ci_bc)	bias-corrected CIs
e(ci_bca)	bias-corrected and accelerated CIs
e(V)	bootstrap variance–covariance matrix
e(V_modelbased)	model-based variance

When *exp_list* is _b, bootstrap will also carry forward most of the results already in e() from *command*.

Methods and formulas

bootstrap is implemented as an ado-file.

Let $\widehat{\theta}$ be the observed value of the statistic, that is, the value of the statistic calculated with the original dataset. Let $i = 1, 2, \ldots, k$ denote the bootstrap samples, and let $\widehat{\theta}_i$ be the value of the statistic from the ith bootstrap sample.

When the `mse` option is specified, the standard error is estimated as

$$\widehat{\text{se}}_{\text{MSE}} = \left\{ \frac{1}{k} \sum_{i=1}^{k} (\widehat{\theta}_i - \widehat{\theta})^2 \right\}^{1/2}$$

Otherwise, the standard error is estimated as

$$\widehat{\text{se}} = \left\{ \frac{1}{k-1} \sum_{i=1}^{k} (\widehat{\theta}_i - \overline{\theta})^2 \right\}^{1/2}$$

where

$$\overline{\theta} = \frac{1}{k} \sum_{i=1}^{k} \widehat{\theta}_i$$

The variance–covariance matrix is similarly computed. The bias is estimated as

$$\widehat{\text{bias}} = \overline{\theta} - \widehat{\theta}$$

Confidence intervals with nominal coverage rates $1 - \alpha$ are calculated according to the following formulas. The normal-approximation method yields the confidence intervals

$$\left[\widehat{\theta} - z_{1-\alpha/2}\, \widehat{\text{se}},\ \widehat{\theta} + z_{1-\alpha/2}\, \widehat{\text{se}} \right]$$

where $z_{1-\alpha/2}$ is the $(1-\alpha/2)$th quantile of the standard normal distribution. If the `mse` option is specified, `bootstrap` will report the normal confidence interval using $\widehat{\text{se}}_{\text{MSE}}$ instead of $\widehat{\text{se}}$. `estat bootstrap` only uses $\widehat{\text{se}}$ in the normal confidence interval.

The percentile method yields the confidence intervals

$$\left[\theta^*_{\alpha/2},\ \theta^*_{1-\alpha/2} \right]$$

where θ^*_p is the pth quantile (the $100p$th percentile) of the bootstrap distribution $(\widehat{\theta}_1, \ldots, \widehat{\theta}_k)$.

Let

$$z_0 = \Phi^{-1}\{\#(\widehat{\theta}_i \leq \widehat{\theta})/k\}$$

where $\#(\widehat{\theta}_i \leq \widehat{\theta})$ is the number of elements of the bootstrap distribution that are less than or equal to the observed statistic and Φ is the standard cumulative normal. z_0 is known as the median bias of $\widehat{\theta}$. Let

$$a = \frac{\sum_{i=1}^{n} (\overline{\theta}_{(\cdot)} - \widehat{\theta}_{(i)})^3}{6\left\{\sum_{i=1}^{n} (\overline{\theta}_{(\cdot)} - \widehat{\theta}_{(i)})^2\right\}^{3/2}}$$

where $\widehat{\theta}_{(i)}$ are the leave-one-out (jackknife) estimates of $\widehat{\theta}$ and $\overline{\theta}_{(\cdot)}$ is their mean. This expression is known as the jackknife estimate of acceleration for $\widehat{\theta}$. Let

$$p_1 = \Phi\left\{ z_0 + \frac{z_0 - z_{1-\alpha/2}}{1 - a(z_0 - z_{1-\alpha/2})} \right\}$$

$$p_2 = \Phi\left\{ z_0 + \frac{z_0 + z_{1-\alpha/2}}{1 - a(z_0 + z_{1-\alpha/2})} \right\}$$

where $z_{1-\alpha/2}$ is the $(1-\alpha/2)$th quantile of the normal distribution. The bias-corrected and accelerated (BC_a) method yields confidence intervals

$$\left[\, \theta^*_{p_1},\, \theta^*_{p_2} \,\right]$$

where θ^*_p is the pth quantile of the bootstrap distribution as defined previously. The bias-corrected (but not accelerated) method is a special case of BC_a with $a = 0$.

Title

bootstrap postestimation — Postestimation tools for bootstrap

Description

The following postestimation command is of special interest after `bootstrap`:

Command	Description
`estat bootstrap`	percentile-based and bias-corrected CI tables

For information about `estat bootstrap`, see below.

The following standard postestimation commands are also available:

Command	Description
*`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
*`hausman`	Hausman's specification test
*`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
*`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
*`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
*`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
*`predict`	predictions, residuals, influence statistics, and other diagnostic measures
*`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
*`pwcompare`	pairwise comparisons of estimates
*`test`	Wald tests of simple and composite linear hypotheses
*`testnl`	Wald tests of nonlinear hypotheses

*This postestimation command is allowed if it may be used after *command*.

See the corresponding entries in the *Stata Base Reference Manual* for details.

Special-interest postestimation command

`estat bootstrap` displays a table of confidence intervals for each statistic from a bootstrap analysis.

Syntax for predict

The syntax of `predict` (and even if `predict` is allowed) following `bootstrap` depends upon the *command* used with `bootstrap`. If `predict` is not allowed, neither is `predictnl`.

Syntax for estat bootstrap

```
estat bootstrap [ , options ]
```

options	Description
bc	bias-corrected CIs; the default
bca	bias-corrected and accelerated (BC_a) CIs
normal	normal-based CIs
percentile	percentile CIs
all	all available CIs
noheader	suppress table header
nolegend	suppress table legend
verbose	display the full table legend

bc, bca, normal, and percentile may be used together.

Menu

Statistics > Postestimation > Reports and statistics

Options for estat bootstrap

bc is the default and displays bias-corrected confidence intervals.

bca displays bias-corrected and accelerated confidence intervals. This option assumes that you also specified the bca option on the bootstrap prefix command.

normal displays normal approximation confidence intervals.

percentile displays percentile confidence intervals.

all displays all available confidence intervals.

noheader suppresses display of the table header. This option implies nolegend.

nolegend suppresses display of the table legend, which identifies the rows of the table with the expressions they represent.

verbose requests that the full table legend be displayed.

Remarks

▷ Example 1

The estat bootstrap postestimation command produces a table containing the observed value of the statistic, an estimate of its bias, the bootstrap standard error, and up to four different confidence intervals.

If we were interested merely in getting bootstrap standard errors for the model coefficients, we could use the bootstrap prefix with our estimation command. If we were interested in performing a thorough bootstrap analysis of the model coefficients, we could use the estat bootstrap postestimation command after fitting the model with the bootstrap prefix.

Using example 1 from [R] **bootstrap**, we need many more replications for the confidence interval types other than the normal based, so let's rerun the estimation command. We will reset the random-number seed—in case we wish to reproduce the results—increase the number of replications, and save the bootstrap distribution as a dataset called `bsauto.dta`.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. set seed 1
. bootstrap _b, reps(1000) saving(bsauto) bca: regress mpg weight gear foreign
  (output omitted)
. estat bootstrap, all
Linear regression                               Number of obs      =        74
                                                Replications       =      1000
```

mpg	Observed Coef.	Bias	Bootstrap Std. Err.	[95% Conf.	Interval]

				-1.262111	4.585372	(P)
				-1.523927	4.174376	(BC)
				-1.492223	4.231356	(BCa)
foreign	-2.2216815	-.0196361	1.2023286	-4.578202	.1348393	(N)
				-4.442199	.2677989	(P)
				-4.155504	.6170642	(BC)
				-4.216531	.5743973	(BCa)
_cons	36.101353	-.502281	5.4089441	25.50002	46.70269	(N)
				24.48569	46.07086	(P)
				25.59799	46.63227	(BC)
				25.85658	47.02108	(BCa)

```
(N)    normal confidence interval
(P)    percentile confidence interval
(BC)   bias-corrected confidence interval
(BCa)  bias-corrected and accelerated confidence interval
```

The estimated standard errors here differ from our previous estimates using only 100 replications by, respectively, 8%, 3%, 11%, and 6%; see example 1 of [R] **bootstrap**. So much for our advice that 50–200 replications are good enough to estimate standard errors. Well, the more replications the better—that advice you should believe.

Which of the methods to compute confidence intervals should we use? If the statistic is unbiased, the percentile (P) and bias-corrected (BC) methods should give similar results. The bias-corrected confidence interval will be the same as the percentile confidence interval when the observed value of the statistic is equal to the median of the bootstrap distribution. Thus, for unbiased statistics, the two methods should give similar results as the number of replications becomes large. For biased statistics, the bias-corrected method should yield confidence intervals with better coverage probability (closer to the nominal value of 95% or whatever was specified) than the percentile method. For statistics with variances that vary as a function of the parameter of interest, the bias-corrected and accelerated method (BC_a) will typically have better coverage probability than the others.

When the bootstrap distribution is approximately normal, all these methods should give similar confidence intervals as the number of replications becomes large. If we examine the normality of these bootstrap distributions using, say, the `pnorm` command (see [R] **diagnostic plots**), we see that they closely follow a normal distribution. Thus here, the normal approximation would also be a valid

choice. The chief advantage of the normal-approximation method is that it (supposedly) requires fewer replications than the other methods. Of course, it should be used only when the bootstrap distribution exhibits normality.

We can load `bsauto.dta` containing the bootstrap distributions for these coefficients:

```
. use bsauto
(bootstrap: regress)
. describe *
              storage  display     value
variable name   type   format      label      variable label
------------------------------------------------------------------------------
_b_weight       float  %9.0g                  _b[weight]
_b_gear_ratio   float  %9.0g                  _b[gear_ratio]
_b_foreign      float  %9.0g                  _b[foreign]
_b_cons         float  %9.0g                  _b[_cons]
```

We can now run other commands, such as `pnorm`, on the bootstrap distributions. As with all standard estimation commands, we can use the `bootstrap` command to replay its output table. The default variable names assigned to the statistics in *exp_list* are `_bs_1`, `_bs_2`, . . . , and each variable is labeled with the associated expression. The naming convention for the extended expressions `_b` and `_se` is to prepend `_b_` and `_se_`, respectively, onto the name of each element of the coefficient vector. Here the first coefficient is `_b[weight]`, so `bootstrap` named it `_b_weight`.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

boxcox — Box–Cox regression models

Syntax

`boxcox` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`noconstant`	suppress constant term
`model(lhsonly)`	left-hand-side Box–Cox model; the default
`model(rhsonly)`	right-hand-side Box–Cox model
`model(lambda)`	both sides Box–Cox model with same parameter
`model(theta)`	both sides Box–Cox model with different parameters
`notrans(`*varlist*`)`	nontransformed independent variables
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`lrtest`	perform likelihood-ratio test
Maximization	
`nolog`	suppress full-model iteration log
`nologlr`	suppress restricted-model `lrtest` iteration log
maximize_options	control the maximization process; seldom used

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`bootstrap`, `by`, `jackknife`, `rolling`, `statsby`, and `xi` are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`fweights` and `iweights` are allowed; see [U] **11.1.6 weight**.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Box-Cox regression

Description

`boxcox` finds the maximum likelihood estimates of the parameters of the Box–Cox transform, the coefficients on the independent variables, and the standard deviation of the normally distributed errors for a model in which *depvar* is regressed on *indepvars*. You can fit the following models:

Option	Estimates
`lhsonly`	$y_j^{(\theta)} = \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + \epsilon_j$
`rhsonly`	$y_j = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \epsilon_j$
`rhsonly notrans()`	$y_j = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \cdots + \gamma_l z_{lj} + \epsilon_j$
`lambda`	$y_j^{(\lambda)} = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \epsilon_j$
`lambda notrans()`	$y_j^{(\lambda)} = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \cdots + \gamma_l z_{lj} + \epsilon_j$
`theta`	$y_j^{(\theta)} = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \epsilon_j$
`theta notrans()`	$y_j^{(\theta)} = \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \cdots + \gamma_l z_{lj} + \epsilon_j$

Any variable to be transformed must be strictly positive.

Options

Model

`noconstant`; see [R] **estimation options**.

`model(` `lhsonly` | `rhsonly` | `lambda` | `theta` `)` specifies which of the four models to fit.

`model(lhsonly)` applies the Box–Cox transform to *depvar* only. `model(lhsonly)` is the default.

`model(rhsonly)` applies the transform to the *indepvars* only.

`model(lambda)` applies the transform to both *depvar* and *indepvars*, and they are transformed by the same parameter.

`model(theta)` applies the transform to both *depvar* and *indepvars*, but this time, each side is transformed by a separate parameter.

`notrans(`*varlist*`)` specifies that the variables in *varlist* be included as nontransformed independent variables.

Reporting

`level(#)`; see [R] **estimation options**.

`lrtest` specifies that a likelihood-ratio test of significance be performed and reported for each independent variable.

Maximization

`nolog` suppresses the iteration log when fitting the full model.

`nologlr` suppresses the iteration log when fitting the restricted models required by the `lrtest` option.

maximize_options: `iterate(#)` and `from(`*init_specs*`)`; see [R] **maximize**.

Model	Initial value specification
`lhsonly`	`from(`θ_0`, copy)`
`rhsonly`	`from(`λ_0`, copy)`
`lambda`	`from(`λ_0`, copy)`
`theta`	`from(`λ_0 θ_0`, copy)`

Remarks

Remarks are presented under the following headings:

Introduction
Theta model
Lambda model
Left-hand-side-only model
Right-hand-side-only model

Introduction

The Box–Cox transform

$$y^{(\lambda)} = \frac{y^{\lambda} - 1}{\lambda}$$

has been widely used in applied data analysis. Box and Cox (1964) developed the transformation and argued that the transformation could make the residuals more closely normal and less heteroskedastic. Cook and Weisberg (1982) discuss the transform in this light. Because the transform embeds several popular functional forms, it has received some attention as a method for testing functional forms, in particular,

$$y^{(\lambda)} = \begin{cases} y - 1 & \text{if } \lambda = 1 \\ \ln(y) & \text{if } \lambda = 0 \\ 1 - 1/y & \text{if } \lambda = -1 \end{cases}$$

Davidson and MacKinnon (1993) discuss this use of the transform. Atkinson (1985) also gives a good general treatment.

Theta model

`boxcox` obtains the maximum likelihood estimates of the parameters for four different models. The most general of the models, the `theta` model, is

$$y_j^{(\theta)} = \beta_0 + \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \gamma_2 z_{2j} + \cdots + \gamma_l z_{lj} + \epsilon_j$$

where $\epsilon \sim N(0, \sigma^2)$. Here the dependent variable, y, is subject to a Box–Cox transform with parameter θ. Each of the *indepvars*, $x_1, x_2, \ldots, x_k$, is transformed by a Box–Cox transform with parameter λ. The $z_1, z_2, \ldots, z_l$ specified in the `notrans()` option are independent variables that are not transformed.

Box and Cox (1964) argued that this transformation would leave behind residuals that more closely follow a normal distribution than those produced by a simple linear regression model. Bear in mind that the normality of ϵ is assumed and that `boxcox` obtains maximum likelihood estimates of the $k+l+4$ parameters under this assumption. `boxcox` does not choose λ and θ so that the residuals are approximately normally distributed. If you are interested in this type of transformation to normality, see the official Stata commands `lnskew0` and `bcskew0` in [R] **lnskew0**. However, those commands work on a more restrictive model in which none of the independent variables is transformed.

▷ Example 1

Consider an example using the auto data.

```

The output is composed of the iteration logs and three distinct tables. The first table contains a standard header for a maximum likelihood estimator and a standard output table for the Box–Cox transform parameters. The second table contains the estimates of the scale-variant parameters. The third table contains the output from likelihood-ratio tests on three standard functional form specifications.

If we were to interpret this output, the right-hand-side transformation would not significantly add to the regression, whereas the left-hand-side transformation would make the 5% but not the 1% cutoff. `price` is certainly not significant, and `foreign` lies right on the 5% cutoff. `weight` is clearly significant. The output also shows that the linear and multiplicative inverse specifications are both strongly rejected. A natural log specification can be rejected at the 5% level but not at the 1% level.

◁

❑ Technical note

Spitzer (1984) showed that the Wald tests of the joint significance of the coefficients of the right-hand-side variables, either transformed or untransformed, are not invariant to changes in the scale of the transformed dependent variable. Davidson and MacKinnon (1993) also discuss this point. This problem demonstrates that Wald statistics can be manipulated in nonlinear models. Lafontaine and White (1986) analyze this problem numerically, and Phillips and Park (1988) analyze it by using Edgeworth expansions. See Drukker (2000b) for a more detailed discussion of this issue. Because the parameter estimates and their Wald tests are not scale invariant, no Wald tests or confidence intervals are reported for these parameters. However, when the `lrtest` option is specified, likelihood-ratio tests are performed and reported. Schlesselman (1971) showed that, if a constant is included in the model, the parameter estimates of the Box–Cox transforms are scale invariant. For this reason, we strongly recommend that you not use the `noconstant` option.

The `lrtest` option does not perform a likelihood-ratio test on the constant, so no value for this statistic is reported. Unless the data are properly scaled, the restricted model does not often converge. For this reason, no likelihood-ratio test on the constant is performed by the `lrtest` option. However, if you have a special interest in performing this test, you can do so by fitting the constrained model separately. If problems with convergence are encountered, rescaling the data by their means may help.

❑

Lambda model

A less general model than the one above is called the `lambda` model. It specifies that the same parameter be used in both the left-hand-side and right-hand-side transformations. Specifically,

$$y_j^{(\lambda)} = \beta_0 + \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \gamma_2 z_{2j} + \cdots + \gamma_l z_{lj} + \epsilon_j$$

where $\epsilon \sim N(0, \sigma^2)$. Here the *depvar* variable, y, and each of the *indepvars*, $x_1, x_2, \ldots, x_k$, is transformed by a Box–Cox transform with the common parameter λ. Again the $z_1, z_2, \ldots, z_l$ are independent variables that are not transformed.

Left-hand-side-only model

Even more restrictive than a common transformation parameter is transforming the dependent variable only. Because the dependent variable is on the left-hand side of the equation, this model is known as the `lhsonly` model. Here you are estimating the parameters of the model

$$y_j^{(\theta)} = \beta_0 + \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + \epsilon_j$$

where $\epsilon \sim N(0, \sigma^2)$. Here only the *depvar*, y, is transformed by a Box–Cox transform with the parameter θ.

▷ Example 2

We again hypothesize `mpg` to be a function of `weight`, `price`, and `foreign` in a Box–Cox model in which only `mpg` is subject to the transform:

```
. boxcox mpg weight price foreign, model(lhs) lrtest nolog nologlr

------------------------------------------------------------------------------
```

This model rejects both linear and log specifications of `mpg` but fails to reject the hypothesis that $1/$`mpg` is linear in the independent variables. These findings are in line with what an engineer would have expected. In engineering terms, gallons per mile represents actual energy consumption, and energy consumption should be approximately linear in weight.

◁

Right-hand-side-only model

The fourth model leaves the *depvar* alone and transforms a subset of the *indepvars* using the parameter λ. This is the `rhsonly` model. In this model, the *depvar*, y, is given by

$$y_j = \beta_0 + \beta_1 x_{1j}^{(\lambda)} + \beta_2 x_{2j}^{(\lambda)} + \cdots + \beta_k x_{kj}^{(\lambda)} + \gamma_1 z_{1j} + \gamma_2 z_{2j} + \cdots + \gamma_l z_{lj} + \epsilon_j$$

where $\epsilon \sim N(0, \sigma^2)$. Here each of the *indepvars*, $x_1, x_2, \ldots, x_k$, is transformed by a Box–Cox transform with the parameter λ. Again the $z_1, z_2, \ldots, z_l$ are independent variables that are not transformed.

▷ Example 3

Here is an example with the `rhsonly` model. `price` and `foreign` are not included in the list of covariates. (You are invited to use the `auto` data and check that they fare no better here than above.)

```
. boxcox mpg weight, model(rhs) lrtest nolog nologlr
Fitting full model
Fitting comparison models for LR tests
Comparison model for LR test on weight is a linear regression.
Lambda is not identified in the restricted model.
                                                Number of obs   =         74
                                                LR chi2(2)      =      82.90

lambda = -1      -193.2893          0.69           0.406
lambda =  0      -193.17892         0.47           0.493
lambda =  1      -195.38869         4.89           0.027
------------------------------------------------------------------------------
```

The interpretation of the output is similar to that in all the cases above, with one caveat. As requested, a likelihood-ratio test was performed on the lone independent variable. However, when it is dropped to form the constrained model, the comparison model is not a right-hand-side-only Box–Cox model but rather a simple linear regression on a constant model. When weight is dropped, there are no longer any transformed variables. Hence, λ is not identified, and it must also be dropped. This process leaves a linear regression on a constant as the "comparison model". It also implies that the test statistic has 2 degrees of freedom instead of 1. At the top of the output, a more concise warning informs you of this point.

A similar identification issue can also arise in the `lambda` and `theta` models when only one independent variable is specified. In these cases, warnings also appear on the output.

◁

Saved results

`boxcox` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(ll)`	log likelihood
`e(chi2)`	LR statistic of full vs. comparison
`e(df_m)`	full model degrees of freedom
`e(ll0)`	log likelihood of the restricted model
`e(df_r)`	restricted model degrees of freedom
`e(ll_t1)`	log likelihood of model $\lambda=\theta=1$
`e(chi2_t1)`	LR of $\lambda=\theta=1$ vs. full model
`e(p_t1)`	p-value of $\lambda=\theta=1$ vs. full model
`e(ll_tm1)`	log likelihood of model $\lambda=\theta=-1$
`e(chi2_tm1)`	LR of $\lambda=\theta=-1$ vs. full model
`e(p_tm1)`	p-value of $\lambda=\theta=-1$ vs. full model
`e(ll_t0)`	log likelihood of model $\lambda=\theta=0$
`e(chi2_t0)`	LR of $\lambda=\theta=0$ vs. full model
`e(p_t0)`	p-value of $\lambda=\theta=0$ vs. full model
`e(rank)`	rank of `e(V)`
`e(ic)`	number of iterations
`e(rc)`	return code

Macros

`e(cmd)`	`boxcox`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(model)`	`lhsonly`, `rhsonly`, `lambda`, or `theta`
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(ntrans)`	`yes` if nontransformed *indepvars*
`e(chi2type)`	`LR`; type of model χ^2 test
`e(lrtest)`	`lrtest`, if requested
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(marginsnotok)`	predictions disallowed by `margins`

Matrices

`e(b)`	coefficient vector
`e(V)`	variance–covariance matrix of the estimators (see note below)
`e(pm)`	p-values for LR tests on *indepvars*
`e(df)`	degrees of freedom of LR tests on *indepvars*
`e(chi2m)`	LR statistics for tests on *indepvars*

Functions

`e(sample)`	marks estimation sample

`e(V)` contains all zeros, except for the elements that correspond to the parameters of the Box–Cox transform.

Methods and formulas

`boxcox` is implemented as an ado-file.

In the internal computations,

$$y^{(\lambda)} = \begin{cases} \frac{y^{\lambda}-1}{\lambda} & \text{if } |\lambda| > 10^{-10} \\ \ln(y) & \text{otherwise} \end{cases}$$

The unconcentrated log likelihood for the `theta` model is

$$\ln L = \left(\frac{-N}{2}\right)\left\{\ln(2\pi) + \ln(\sigma^2)\right\} + (\theta-1)\sum_{i=1}^{N}\ln(y_i) - \left(\frac{1}{2\sigma^2}\right)\mathrm{SSR}$$

where

$$\mathrm{SSR} = \sum_{i=1}^{N}(y_i^{(\theta)} - \beta_0 + \beta_1 x_{i1}^{(\lambda)} + \beta_2 x_{i2}^{(\lambda)} + \cdots + \beta_k x_{ik}^{(\lambda)} + \gamma_1 z_{i1} + \gamma_2 z_{i2} + \cdots + \gamma_l z_{il})^2$$

Writing the SSR in matrix form,

$$\mathrm{SSR} = (\mathbf{Y}^{(\theta)} - \mathbf{X}^{(\lambda)}\mathbf{b}' - \mathbf{Z}\mathbf{g}')'(\mathbf{Y}^{(\theta)} - \mathbf{X}^{(\lambda)}\mathbf{b}' - \mathbf{Z}\mathbf{g}')$$

where $\mathbf{Y}^{(\theta)}$ is an $N \times 1$ vector of elementwise transformed data, $\mathbf{X}^{(\lambda)}$ is an $N \times k$ matrix of elementwise transformed data, $\mathbf{Z}$ is an $N \times l$ matrix of untransformed data, $\mathbf{b}$ is a $1 \times k$ vector of coefficients, and $\mathbf{g}$ is a $1 \times l$ vector of coefficients. Letting

$$\mathbf{W}_\lambda = \left(\mathbf{X}^{(\lambda)}\ \mathbf{Z}\right)$$

be the horizontal concatenation of $\mathbf{X}^{(\lambda)}$ and $\mathbf{Z}$ and

$$\mathbf{d}' = \begin{pmatrix} \mathbf{b}' \\ \mathbf{g}' \end{pmatrix}$$

be the vertical concatenation of the coefficients yields

$$\mathrm{SSR} = (\mathbf{Y}^{(\theta)} - \mathbf{W}_\lambda\mathbf{d}')'(\mathbf{Y}^{(\theta)} - \mathbf{W}_\lambda\mathbf{d}')$$

For given values of λ and θ, the solutions for $\mathbf{d}'$ and σ^2 are

$$\widehat{\mathbf{d}}' = (\mathbf{W}_\lambda'\mathbf{W}_\lambda)^{-1}\mathbf{W}_\lambda'\mathbf{Y}^{(\theta)}$$

and

$$\widehat{\sigma}^{\,2} = \frac{1}{N}\left(\mathbf{Y}^{(\theta)} - \mathbf{W}_\lambda\widehat{\mathbf{d}}'\right)'\left(\mathbf{Y}^{(\theta)} - \mathbf{W}_\lambda\widehat{\mathbf{d}}'\right)$$

Substituting these solutions into the log-likelihood function yields the concentrated log-likelihood function

$$\ln L_c = \left(-\frac{N}{2}\right)\left\{\ln(2\pi) + 1 + \ln(\widehat{\sigma}^{\,2})\right\} + (\theta-1)\sum_{i=1}^{N}\ln(y_i)$$

Similar calculations yield the concentrated log-likelihood function for the `lambda` model,

$$\ln L_c = \left(-\frac{N}{2}\right)\left\{\ln(2\pi) + 1 + \ln(\widehat{\sigma}^{\,2})\right\} + (\lambda - 1)\sum_{i=1}^{N}\ln(y_i)$$

the `lhsonly` model,

$$\ln L_c = \left(-\frac{N}{2}\right)\left\{\ln(2\pi) + 1 + \ln(\widehat{\sigma}^{\,2})\right\} + (\theta - 1)\sum_{i=1}^{N}\ln(y_i)$$

and the `rhsonly` model,

$$\ln L_c = \left(-\frac{N}{2}\right)\left\{\ln(2\pi) + 1 + \ln(\widehat{\sigma}^{\,2})\right\}$$

where $\widehat{\sigma}^{\,2}$ is specific to each model and is defined analogously to that in the `theta` model.

Title

boxcox postestimation — Postestimation tools for boxcox

Description

The following postestimation commands are available after `boxcox`:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
*`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
*`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
*`test`	Wald tests of simple and composite linear hypotheses
*`testnl`	Wald tests of nonlinear hypotheses

*Inference is valid only for hypotheses concerning λ and θ.

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` *statistic*]

statistic	Description
Main	
`xbt`	transformed linear prediction; the default
`yhat`	predicted value of y
`residuals`	residuals

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xbt`, the default, calculates the "linear" prediction. For all the models except `model(lhsonly)`, all the *indepvars* except those specified in the `notrans()` option of `boxcox` are transformed.

`yhat` calculates the predicted value of y.

`residuals` calculates the residuals after the predicted value of y has been subtracted from the actual value.

Remarks

`boxcox` estimates variances only for the λ and θ parameters (see the technical note in [R] **boxcox**), so the extent to which postestimation commands can be used following `boxcox` is limited. Formulas used in `lincom`, `nlcom`, `test`, and `testnl` are dependent on the estimated variances. Therefore, the use of these commands is limited and generally applicable only to inferences on the λ and θ coefficients.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

brier — Brier score decomposition

Syntax

`brier` *outcomevar forecastvar* [*if*] [*in*] [`, group(#)`]

`by` is allowed; see [D] **by**.

Menu

Statistics > Epidemiology and related > Other > Brier score decomposition

Description

`brier` computes the Yates, Sanders, and Murphy decompositions of the Brier Mean Probability Score. *outcomevar* contains 0/1 values reflecting the actual outcome of the experiment, and *forecastvar* contains the corresponding probabilities as predicted by, say, logit, probit, or a human forecaster.

Option

Main

`group(#)` specifies the number of groups that will be used to compute the decomposition. `group(10)` is the default.

Remarks

You have a binary (0/1) response and a formula that predicts the corresponding probabilities of having observed a positive outcome (1). If the probabilities were obtained from logistic regression, there are many methods that assess goodness of fit (see, for instance, `estat gof` in [R] **logistic**). However, the probabilities might be computed from a published formula or from a model fit on another sample, both completely unrelated to the data at hand, or perhaps the forecasts are not from a formula at all. In any case, you now have a *test dataset* consisting of the forecast probabilities and observed outcomes. Your test dataset might, for instance, record predictions made by a meteorologist on the probability of rain along with a variable recording whether it actually rained.

The Brier score is an aggregate measure of disagreement between the observed outcome and a prediction—the average squared error difference. The Brier score decomposition is a partition of the Brier score into components that suggest reasons for discrepancy. These reasons fall roughly into three groups: 1) lack of overall calibration between the average predicted probability and the actual probability of the event in your data, 2) misfit of the data in groups defined within your sample, and 3) inability to match actual 0 and 1 responses.

Problem 1 refers to simply overstating or understating the probabilities.

Problem 2 refers to what is standardly called a goodness-of-fit test: the data are grouped, and the predictions for the group are compared with the outcomes.

Problem 3 refers to an individual-level measure of fit. Imagine that the grouped outcomes are predicted on average correctly but that within the group, the outcomes are poorly predicted.

Using logit or probit analysis to fit your data will guarantee that there is no lack of fit due to problem 1, and a good model fitter will be able to avoid problem 2. Problem 3 is inherent in any prediction exercise.

▷ Example 1

We have data on the outcomes of 20 basketball games (`win`) and the probability of victory predicted by a local pundit (`for`).

```
. use http://www.stata-press.com/data/r12/bball
. summarize win for
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
         win |        20         .65    .4893605          0          1
         for |        20       .4785    .2147526        .15         .9
. brier win for, group(5)
Mean probability of outcome   0.6500
                of forecast   0.4785
Correlation                   0.5907
ROC area                      0.8791  p = 0.0030
Brier score                   0.1828
Spiegelhalter's z-statistic  -0.6339  p = 0.7369
Sanders-modified Brier score  0.1861
Sanders resolution            0.1400
Outcome index variance        0.2275
Murphy resolution             0.0875
Reliability-in-the-small      0.0461
Forecast variance             0.0438
Excess forecast variance      0.0285
Minimum forecast variance     0.0153
Reliability-in-the-large      0.0294
2*Forecast-Outcome-Covar      0.1179
```

The mean probabilities of forecast and outcome are simply the mean of the predicted probabilities and the actual outcomes (wins/losses). The correlation is the product-moment correlation between them.

The Brier score measures the total difference between the event (winning) and the forecast probability of that event as an average squared difference. As a benchmark, a perfect forecaster would have a Brier score of 0, a perfect misforecaster (predicts probability of win is 1 when loses and 0 when wins) would have a Brier score of 1, and a fence-sitter (forecasts every game as 50/50) would have a Brier score of 0.25. Our pundit is doing reasonably well.

Spiegelhalter's z statistic is a standard normal test statistic for testing whether an individual Brier score is extreme. The ROC area is the area under the receiver operating curve, and the associated test is a test of whether it is greater than 0.5. The more accurate the forecast probabilities, the larger the ROC area.

The Sanders-modified Brier score measures the difference between a grouped forecast measure and the event, where the data are grouped by sorting the sample on the forecast and dividing it into approximately equally sized groups. The difference between the modified and the unmodified score is typically minimal. For this and the other statistics that require grouping—the Sanders and Murphy resolutions and reliability-in-the-small—to be well-defined, group boundaries are chosen so as not to allocate observations with the same forecast probability to different groups. This task is done by grouping on the forecast using `xtile, n(#)`, with # being the number of groups; see [D] **pctile**.

The Sanders resolution measures error that arises from statistical considerations in evaluating the forecast for a group. A group with all positive or all negative outcomes would have a Sanders resolution of 0; it would most certainly be feasible to predict exactly what happened to each member of the group. If the group had 40% positive responses, on the other hand, a forecast that assigned $p = 0.4$ to each member of the group would be a good one, and yet, there would be "errors" in the squared difference sense. The "error" would be $(1 - 0.4)^2$ or $(0 - 0.4)^2$ for each member. The Sanders resolution is the average across groups of such "expected" errors. The 0.1400 value in our data from an overall Brier score of 0.1828 or 0.1861 suggests that a substantial portion of the "error" in our data is inherent.

Outcome index variance is just the variance of the outcome variable. This is the expected value of the Brier score if all the forecast probabilities were merely the average observed outcome. Remember that a fence-sitter has an expected Brier score of 0.25; a smarter fence sitter (who would guess $p = 0.65$ for these data) would have a Brier score of 0.2275.

The Murphy resolution measures the variation in the average outcomes across groups. If all groups have the same frequency of positive outcomes, little information in any forecast is possible, and the Murphy resolution is 0. If groups differ markedly, the Murphy resolution is as large as 0.25. The 0.0875 means that there is some variation but not a lot, and 0.0875 is probably higher than in most real cases. If you had groups in your data that varied between 40% and 60% positive outcomes, the Murphy resolution would be 0.01; between 30% and 70%, it would be 0.04.

Reliability-in-the-small measures the error that comes from the average forecast within group not measuring the average outcome within group—a classical goodness-of-fit measure, with 0 meaning a perfect fit and 1 meaning a complete lack of fit. The calculated value of 0.0461 shows some amount of lack of fit. Remember, the number is squared, and we are saying that probabilities could be just more than $\sqrt{0.0461} = 0.215$ or 21.5% off.

Forecast variance measures the amount of discrimination being attempted—that is, the variation in the forecasted probabilities. A small number indicates a fence-sitter making constant predictions. If the forecasts were from a logistic regression model, forecast variance would tend to increase with the amount of information available. Our pundit shows considerable forecast variance of 0.0438 (standard deviation $\sqrt{0.0438} = 0.2093$), which is in line with the reliability-in-the-small, suggesting that the forecaster is attempting as much variation as is available in these data.

Excess forecast variance is the amount of actual forecast variance over a theoretical minimum. The theoretical minimum—called the minimum forecast variance—corresponds to forecasts of p_0 for observations ultimately observed to be negative responses and p_1 for observations ultimately observed to be positive outcomes. Moreover, p_0 and p_1 are set to the average forecasts made for the ultimate negative and positive outcomes. These predictions would be just as good as the predictions the forecaster did make, and any variation in the actual forecast probabilities above this is useless. If this number is large, above 1%–2%, then the forecaster may be attempting more than is possible. The 0.0285 in our data suggests this possibility.

Reliability-in-the-large measures the discrepancy between the mean forecast and the observed fraction of positive outcomes. This discrepancy will be 0 for forecasts made by most statistical models—at least when measured on the same sample used for estimation—because they, by design, reproduce sample means. For our human pundit, the 0.0294 says that there is a $\sqrt{0.0294}$, or 17-percentage-point, difference. (This difference can also be found by calculating the difference in the averages of the observed outcomes and forecast probabilities: $0.65 - 0.4785 = 0.17$.) That difference, however, is not significant, as we would see if we typed `ttest win=for`; see [R] **ttest**. If these data were larger and the bias persisted, this difference would be a critical shortcoming of the forecast.

Twice the forecast-outcome covariance is a measure of how accurately the forecast corresponds to the outcome. The concept is similar to that of R-squared in linear regression.

◁

Saved results

`brier` saves the following in `r()`:

Scalars

`r(p_roc)`	significance of ROC area	`r(murphy)`	Murphy resolution
`r(roc_area)`	ROC area	`r(relinsm)`	reliability-in-the-small
`r(z)`	Spiegelhalter's z statistic	`r(Var_f)`	forecast variance
`r(p)`	significance of z statistic	`r(Var_fex)`	excess forecast variance
`r(brier)`	Brier score	`r(Var_fmin)`	minimum forecast variance
`r(brier_s)`	Sanders-modified Brier score	`r(relinla)`	reliability-in-the-large
`r(sanders)`	Sanders resolution	`r(cov_2f)`	2×forecast-outcome-covariance
`r(oiv)`	outcome index variance		

Methods and formulas

`brier` is implemented as an ado-file.

See Wilks (2006, 284–287, 289–292, 298–299) or Schmidt and Griffith (2005) for a discussion of the Brier score.

Let d_j, $j = 1, \ldots, N$, be the observed outcomes with $d_j = 0$ or $d_j = 1$, and let f_j be the corresponding forecasted probabilities that d_j is 1, $0 \leq f_j \leq 1$. Assume that the data are ordered so that $f_{j+1} \geq f_j$ (`brier` sorts the data to obtain this order). Divide the data into K nearly equally sized groups, with group 1 containing observations 1 through $j_2 - 1$, group 2 containing observations j_2 through $j_3 - 1$, and so on.

Define

$$\begin{aligned}
\overline{f}_0 &= \text{average } f_j \text{ among } d_j = 0 \\
\overline{f}_1 &= \text{average } f_j \text{ among } d_j = 1 \\
\overline{f} &= \text{average } f_j \\
\overline{d} &= \text{average } d_j \\
\widetilde{f}_k &= \text{average } f_j \text{ in group } k \\
\widetilde{d}_k &= \text{average } d_j \text{ in group } k \\
\widetilde{n}_k &= \text{number of observations in group } k
\end{aligned}$$

The Brier score is $\sum_j (d_j - f_j)^2/N$.

The Sanders-modified Brier score is $\sum_j (d_j - \widetilde{f}_{k(j)})^2/N$.

Let p_j denote the true but unknown probability that $d_j = 1$. Under the null hypothesis that $p_j = f_j$ for all j, Spiegelhalter (1986) determined that the expectation and variance of the Brier score is given by the following:

$$E(\text{Brier}) = \frac{1}{N}\sum_{j=1}^{N} f_j(1-f_j)$$

$$\text{Var}(\text{Brier}) = \frac{1}{N^2}\sum_{j=1}^{N} f_j(1-f_j)(1-2f_j)^2$$

Denoting the observed value of the Brier score by $O(\text{Brier})$, Spiegelhalter's z statistic is given by

$$Z = \frac{O(\text{Brier}) - E(\text{Brier})}{\sqrt{\text{Var}(\text{Brier})}}$$

The corresponding p-value is given by the upper-tail probability of Z under the standard normal distribution.

The area under the ROC curve is estimated by applying the trapezoidal rule to the empirical ROC curve. This area is Wilcoxon's test statistic, so the corresponding p-value is just that of a one-sided Wilcoxon test of the null hypothesis that the distribution of predictions is constant across the two outcomes.

The Sanders resolution is $\sum_k \widetilde{n}_k\{\widetilde{d}_k(1-\widetilde{d}_k)\}/N$.

The outcome index variance is $\overline{d}(1-\overline{d})$.

The Murphy resolution is $\sum_k \widetilde{n}_k(\widetilde{d}_k - \overline{d})^2/N$.

Reliability-in-the-small is $\sum_k \widetilde{n}_k(\widetilde{d}_k - \widetilde{f}_k)^2/N$.

The forecast variance is $\sum_j (f_j - \overline{f})^2/N$.

The minimum forecast variance is $\{\sum_{j\in F}(f_j - \overline{f}_0)^2 + \sum_{j\in S}(f_j - \overline{f}_1)^2\}/N$, where F is the set of observations for which $d_j = 0$ and S is the complement.

The excess forecast variance is the difference between the forecast variance and the minimum forecast variance.

Reliability-in-the-large is $(\overline{f} - \overline{d})^2$.

Twice the outcome covariance is $2(\overline{f}_1 - \overline{f}_0)\overline{d}(1-\overline{d})$.

Glenn Wilson Brier (1913–1998) was an American meteorological statistician who, after obtaining degrees in physics and statistics, was for many years head of meteorological statistics at the U.S. Weather Bureau in Washington, DC. In the latter part of his career, he was associated with Colorado State University. Brier worked especially on verification and evaluation of predictions and forecasts, statistical decision making, the statistical theory of turbulence, the analysis of weather modification experiments, and the application of permutation techniques.

Acknowledgment

We thank Richard Goldstein for his contributions to this improved version of `brier`.

Title

bsample — Sampling with replacement

Syntax

`bsample` [*exp*] [*if*] [*in*] [, *options*]

where *exp* is a standard Stata expression; see [U] **13 Functions and expressions**.

options	Description
`strata(`*varlist*`)`	variables identifying strata
`cluster(`*varlist*`)`	variables identifying resampling clusters
`idcluster(`*newvar*`)`	create new cluster ID variable
`weight(`*varname*`)`	replace *varname* with frequency weights

Menu

Statistics > Resampling > Draw bootstrap sample

Description

`bsample` draws bootstrap samples (random samples with replacement) from the data in memory.

exp specifies the size of the sample, which must be less than or equal to the number of sampling units in the data. The observed number of units is the default when *exp* is not specified.

For bootstrap sampling of the observations, *exp* must be less than or equal to `_N` (the number of observations in the data; see [U] **13.4 System variables (_variables)**).

For stratified bootstrap sampling, *exp* must be less than or equal to `_N` within the strata identified by the `strata()` option.

For clustered bootstrap sampling, *exp* must be less than or equal to N_c (the number of clusters identified by the `cluster()` option).

For stratified bootstrap sampling of clusters, *exp* must be less than or equal to N_c within the strata identified by the `strata()` option.

Observations that do not meet the optional `if` and `in` criteria are dropped (not sampled).

Options

`strata(`*varlist*`)` specifies the variables identifying strata. If `strata()` is specified, bootstrap samples are selected within each stratum.

`cluster(`*varlist*`)` specifies the variables identifying resampling clusters. If `cluster()` is specified, the sample drawn during each replication is a bootstrap sample of clusters.

`idcluster(`*newvar*`)` creates a new variable containing a unique identifier for each resampled cluster.

`weight(`*varname*`)` specifies a variable in which the sampling frequencies will be placed. *varname* must be an existing variable, which will be replaced. After `bsample`, *varname* can be used as an `fweight` in any Stata command that accepts `fweight`s, which can speed up resampling for commands like `regress` and `summarize`. This option cannot be combined with `idcluster()`.

By default, `bsample` replaces the data in memory with the sampled observations; however, specifying the `weight()` option causes only the specified *varname* to be changed.

Remarks

Below is a series of examples illustrating how `bsample` is used with various sampling schemes.

▷ Example 1: Bootstrap sampling

We have data on the characteristics of hospital patients and wish to draw a bootstrap sample of 200 patients. We type

```
. use http://www.stata-press.com/data/r12/bsample1
. bsample 200
. count
  200
```

◁

▷ Example 2: Stratified samples with equal sizes

Among the variables in our dataset is `female`, an indicator for the female patients. To get a bootstrap sample of 200 female patients and 200 male patients, we type

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. bsample 200, strata(female)
. tab female
```

female	Freq.	Percent	Cum.
male	200	50.00	50.00
female	200	50.00	100.00
Total	400	100.00	

◁

▷ Example 3: Stratified samples with unequal sizes

To sample 300 females and 200 males, we must generate a variable that is 300 for females and 200 for males and then use this variable in *exp* when we call `bsample`.

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. gen nsamp = cond(female,300,200)
. bsample nsamp, strata(female)
. tab female
```

female	Freq.	Percent	Cum.
male	200	40.00	40.00
female	300	60.00	100.00
Total	500	100.00	

◁

▷ Example 4: Samples satisfying a condition

For a bootstrap sample of 200 female patients, we type

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. bsample 200 if female
. tab female
```

female	Freq.	Percent	Cum.
female	200	100.00	100.00
Total	200	100.00	

◁

▷ Example 5: Generating frequency weights

To identify the sampled observations using frequency weights instead of dropping unsampled observations, we use the `weight()` option (we will need to supply it an existing variable name) and type

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. set seed 1234
. gen fw = .
(5810 missing values generated)
. bsample 200 if female, weight(fw)
. tabulate fw female
```

	female		
fw	male	female	Total
0	2,392	3,221	5,613
1	0	194	194
2	0	3	3
Total	2,392	3,418	5,810

Note that $(194 \times 1) + (3 \times 2) = 200$.

◁

▷ Example 6: Oversampling observations

`bsample` requires the expression in *exp* to evaluate to a number that is less than or equal to the number of observations. To sample twice as many male and female patients as there are already in memory, we must expand the data before using `bsample`. For example,

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. set seed 1234
. expand 2
(5810 observations created)
. bsample, strata(female)
```

```
. tab female
```

female	Freq.	Percent	Cum.
male	4,784	41.17	41.17
female	6,836	58.83	100.00
Total	11,620	100.00	

◁

▷ Example 7: Stratified oversampling with unequal sizes

To sample twice as many female patients as male patients, we must expand the records for the female patients because there are less than twice as many of them as there are male patients, but first put the number of observed male patients in a local macro. After expanding the female records, we generate a variable that contains the number of observations to sample within the two groups.

```
. use http://www.stata-press.com/data/r12/bsample1, clear
. set seed 1234
. count if !female
 2392
. local nmale = r(N)
. expand 2 if female
(3418 observations created)
. gen nsamp = cond(female,2*`nmale',`nmale')
. bsample nsamp, strata(female)
. tab female
```

female	Freq.	Percent	Cum.
male	2,392	33.33	33.33
female	4,784	66.67	100.00
Total	7,176	100.00	

◁

▷ Example 8: Oversampling of clusters

For clustered data, sampling more clusters than are present in the original dataset requires more than just expanding the data. To illustrate, suppose we wanted a bootstrap sample of eight clusters from a dataset consisting of five clusters of observations.

```
. use http://www.stata-press.com/data/r12/bsample2, clear
. tabstat x, stat(n mean) by(group)
Summary for variables: x
     by categories of: group
```

group	N	mean
A	15	-.3073028
B	10	-.00984
C	11	.0810985
D	11	-.1989179
E	29	-.095203
Total	76	-.1153269

`bsample` will complain if we simply expand the dataset.

```
. use http://www.stata-press.com/data/r12/bsample2
. expand 3
(152 observations created)
. bsample 8, cluster(group)
resample size must not be greater than number of clusters
r(498);
```

Expanding the data will only partly solve the problem. We also need a new variable that uniquely identifies the copied clusters. We use the `expandcl` command to accomplish both these tasks; see [D] **expandcl**.

```
. use http://www.stata-press.com/data/r12/bsample2, clear
. set seed 1234
. expandcl 2, generate(expgroup) cluster(group)
(76 observations created)
. tabstat x, stat(n mean) by(expgroup)
Summary for variables: x
     by categories of: expgroup
```

expgroup	N	mean
1	15	-.3073028
2	15	-.3073028
3	10	-.00984
4	10	-.00984
5	11	.0810985
6	11	.0810985
7	11	-.1989179
8	11	-.1989179
9	29	-.095203
10	29	-.095203
Total	152	-.1153269

```
. gen fw = .
(152 missing values generated)
. bsample 8, cluster(expgroup) weight(fw)
. tabulate fw group
```

	group					
fw	A	B	C	D	E	Total
0	15	10	0	0	29	54
1	15	10	22	22	0	69
2	0	0	0	0	29	29
Total	30	20	22	22	58	152

The results from `tabulate` on the generated frequency weight variable versus the original cluster ID (`group`) show us that the bootstrap sample contains one copy of cluster `A`, one copy of cluster `B`, two copies of cluster `C`, two copies of cluster `D`, and two copies of cluster `E` ($1 + 1 + 2 + 2 + 2 = 8$).

◁

▷ Example 9: Stratified oversampling of clusters

Suppose that we have a dataset containing two strata with five clusters in each stratum, but the cluster identifiers are not unique between the strata. To get a stratified bootstrap sample with eight clusters in each stratum, we first use `expandcl` to expand the data and get a new cluster ID variable. We use `cluster(strid group)` in the call to `expandcl`; this action will uniquely identify the $2 * 5 = 10$ clusters across the strata.

```
. use http://www.stata-press.com/data/r12/bsample2, clear
. set seed 1234
. tab group strid
```

group	strid 1	2	Total
A	7	8	15
B	5	5	10
C	5	6	11
D	5	6	11
E	14	15	29
Total	36	40	76

```
. expandcl 2, generate(expgroup) cluster(strid group)
(76 observations created)
```

Now we can use `bsample` with the expanded data, stratum ID variable, and new cluster ID variable.

```
. gen fw = .
(152 missing values generated)
. bsample 8, cluster(expgroup) str(strid) weight(fw)
. by strid, sort: tabulate fw group
```

```
-> strid = 1
```

fw	group A	B	C	D	E	Total
0	0	5	0	5	14	24
1	14	5	10	5	0	34
2	0	0	0	0	14	14
Total	14	10	10	10	28	72

```
-> strid = 2
```

fw	group A	B	C	D	E	Total
0	8	10	0	6	0	24
1	8	0	6	6	15	35
2	0	0	6	0	15	21
Total	16	10	12	12	30	80

The results from `by strid: tabulate` on the generated frequency weight variable versus the original cluster ID (`group`) show us how many times each cluster was sampled for each stratum. For stratum `1`, the bootstrap sample contains two copies of cluster `A`, one copy of cluster `B`, two copies of cluster `C`, one copy of cluster `D`, and two copies of cluster `E` ($2 + 1 + 2 + 1 + 2 = 8$). For stratum `2`, the bootstrap sample contains one copy of cluster `A`, zero copies of cluster `B`, three copies of cluster `C`, one copy of cluster `D`, and three copies of cluster `E` ($1 + 0 + 3 + 1 + 3 = 8$). ◁

Methods and formulas

`bsample` is implemented as an ado-file.

Title

bstat — Report bootstrap results

Syntax

Bootstrap statistics from variables

`bstat` [*varlist*] [*if*] [*in*] [, *options*]

Bootstrap statistics from file

`bstat` [*namelist*] [`using` *filename*] [*if*] [*in*] [, *options*]

options	Description
Main	
`stat(`*vector*`)`	observed values for each statistic
`accel(`*vector*`)`	acceleration values for each statistic
`mse`	use MSE formula for variance estimation
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`n(#)`	# of observations from which bootstrap samples were taken
`notable`	suppress table of results
`noheader`	suppress table header
`nolegend`	suppress table legend
`verbose`	display the full table legend
`title(`*text*`)`	use *text* as title for bootstrap results
display_options	control column formats and line width

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Resampling > Report bootstrap results

Description

`bstat` is a programmer's command that computes and displays estimation results from bootstrap statistics.

For each variable in *varlist* (the default is all variables), then `bstat` computes a covariance matrix, estimates bias, and constructs several different confidence intervals (CIs). The following CIs are constructed by `bstat`:

1. Normal CIs (using the normal approximation)
2. Percentile CIs
3. Bias-corrected (BC) CIs
4. Bias-corrected and accelerated (BC_a) CIs (optional)

`estat bootstrap` displays a table of one or more of the above confidence intervals; see [R] **bootstrap postestimation**.

If there are bootstrap estimation results in `e()`, `bstat` replays them. If given the `using` modifier, `bstat` uses the data in *filename* to compute the bootstrap statistics while preserving the data currently in memory. Otherwise, `bstat` uses the data in memory to compute the bootstrap statistics.

The following options may be used to replay estimation results from `bstat`:

`level(#) notable noheader nolegend verbose title(`*text*`)`

For all other options and the qualifiers `using`, `if`, and `in`, `bstat` requires a bootstrap dataset.

Options

Main

`stat(`*vector*`)` specifies the observed value of each statistic (that is, the value of the statistic using the original dataset).

`accel(`*vector*`)` specifies the acceleration of each statistic, which is used to construct BC$_a$ CIs.

`mse` specifies that `bstat` compute the variance by using deviations of the replicates from the observed value of the statistics. By default, `bstat` computes the variance by using deviations from the average of the replicates.

Reporting

`level(#)`; see [R] **estimation options**.

`n(#)` specifies the number of observations from which bootstrap samples were taken. This value is used in no calculations but improves the table header when this information is not saved in the bootstrap dataset.

`notable` suppresses the display of the output table.

`noheader` suppresses the display of the table header. This option implies `nolegend`.

`nolegend` suppresses the display of the table legend.

`verbose` specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`title(`*text*`)` specifies a title to be displayed above the table of bootstrap results; the default title is `Bootstrap results`.

display_options: `cformat(`*%fmt*`)`, `pformat(`*%fmt*`)`, `sformat(`*%fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Bootstrap datasets
Creating a bootstrap dataset

Bootstrap datasets

Although bstat allows you to specify the observed value and acceleration of each bootstrap statistic via the stat() and accel() options, programmers may be interested in what bstat uses when these options are not supplied.

When working from a bootstrap dataset, bstat first checks the data characteristics (see [P] **char**) that it understands:

_dta[bs_version] identifies the version of the bootstrap dataset. This characteristic may be empty (not defined), 2, or 3; otherwise, bstat will quit and display an error message. This version tells bstat which other characteristics to look for in the bootstrap dataset.

bstat uses the following characteristics from version 3 bootstrap datasets:

_dta[N]
_dta[N_strata]
_dta[N_cluster]
_dta[command]
varname[observed]
varname[acceleration]
varname[expression]

bstat uses the following characteristics from version 2 bootstrap datasets:

_dta[N]
_dta[N_strata]
_dta[N_cluster]
varname[observed]
varname[acceleration]

An empty bootstrap dataset version implies that the dataset was created by the bstrap command in a version of Stata earlier than Stata 8. Here bstat expects *varname*[bstrap] to contain the observed value of the statistic identified by *varname* (*varname*[observed] in version 2). All other characteristics are ignored.

_dta[N] is the number of observations in the observed dataset. This characteristic may be overruled by specifying the n() option.

_dta[N_strata] is the number of strata in the observed dataset.

_dta[N_cluster] is the number of clusters in the observed dataset.

_dta[command] is the command used to compute the observed values of the statistics.

varname[observed] is the observed value of the statistic identified by *varname*. To specify a different value, use the stat() option.

varname[acceleration] is the estimate of acceleration for the statistic identified by *varname*. To specify a different value, use the accel() option.

varname[expression] is the expression or label that describes the statistic identified by *varname*.

Creating a bootstrap dataset

Suppose that we are interested in obtaining bootstrap statistics by resampling the residuals from a regression (which is not possible with the bootstrap command). After loading some data, we run a regression, save some results relevant to the bstat command, and save the residuals in a new variable, res.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight length
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =   69.34
       Model |  1616.08062     2  808.040312            Prob > F      =  0.0000
    Residual |  827.378835    71   11.653223            R-squared     =  0.6614
-------------+------------------------------           Adj R-squared =  0.6519
       Total |  2443.45946    73  33.4720474            Root MSE      =  3.4137

------------------------------------------------------------------------------
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0038515   .001586    -2.43   0.018    -.0070138   -.0006891
      length |  -.0795935   .0553577   -1.44   0.155    -.1899736    .0307867
       _cons |   47.88487   6.08787     7.87   0.000       35.746    60.02374
------------------------------------------------------------------------------
. matrix b = e(b)
. local n = e(N)
. predict res, residuals
```

We can resample the residual values in `res` by generating a random observation ID (`rid`), generate a new response variable (`y`), and run the original regression with the new response variables.

```
. set seed 54321
. gen rid = int(_N*runiform())+1
. matrix score double y = b
. replace y = y + res[rid]
(74 real changes made)
. regress y weight length
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =  103.41
       Model |  1773.23548     2  886.617741            Prob > F      =  0.0000
    Residual |  608.747732    71  8.57391172            R-squared     =  0.7444
-------------+------------------------------           Adj R-squared =  0.7372
       Total |  2381.98321    73   32.629907            Root MSE      =  2.9281

------------------------------------------------------------------------------
           y |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0059938   .0013604    -4.41   0.000    -.0087064   -.0032813
      length |  -.0127875   .0474837    -0.27   0.788    -.1074673    .0818924
       _cons |   42.23195   5.22194     8.09   0.000       31.8197    52.6442
------------------------------------------------------------------------------
```

Instead of programming this resampling inside a loop, it is much more convenient to write a short program and use the `simulate` command; see [R] **simulate**. In the following, `mysim_r` requires the user to specify a coefficient vector and a residual variable. `mysim_r` then retrieves the list of predictor variables (removing `_cons` from the list), generates a new temporary response variable with the resampled residuals, and regresses the new response variable on the predictors.

```
program mysim_r
        version 12
        syntax name(name=bvector), res(varname)
        tempvar y rid
        local xvars : colnames `bvector'
        local cons _cons
        local xvars : list xvars - cons
        matrix score double `y' = `bvector'
        gen long `rid' = int(_N*runiform()) + 1
        replace `y' = `y' + `res'[`rid']
        regress `y' `xvars'
end
```

We can now give `mysim_r` a test run, but we first set the random-number seed (to reproduce results).

```
. set seed 54321
. mysim_r b, res(res)
(74 real changes made)
```

Source	SS	df	MS		
Model	1773.23548	2	886.617741	Number of obs	= 74
Residual	608.747732	71	8.57391172	F(2, 71)	= 103.41
				Prob > F	= 0.0000
Total	2381.98321	73	32.629907	R-squared	= 0.7444
				Adj R-squared	= 0.7372
				Root MSE	= 2.9281

__000000	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.0059938	.0013604	-4.41	0.000	-.0087064	-.0032813
length	-.0127875	.0474837	-0.27	0.788	-.1074673	.0818924
_cons	42.23195	5.22194	8.09	0.000	31.8197	52.6442

Now that we have a program that will compute the results we want, we can use `simulate` to generate a bootstrap dataset and `bstat` to display the results.

```
. set seed 54321
. simulate, reps(200) nodots: mysim_r b, res(res)
      command:  mysim_r b, res(res)
. bstat, stat(b) n(`n')
Bootstrap results                               Number of obs      =        74
                                                Replications       =       200
```

	Observed Coef.	Bootstrap Std. Err.	z	P>|z|	Normal-based [95% Conf.	Interval]
_b_weight	-.0038515	.0015715	-2.45	0.014	-.0069316	-.0007713
_b_length	-.0795935	.0552415	-1.44	0.150	-.1878649	.0286779
_b_cons	47.88487	6.150069	7.79	0.000	35.83096	59.93879

Finally, we see that `simulate` created some of the data characteristics recognized by `bstat`. All we need to do is correctly specify the version of the bootstrap dataset, and `bstat` will automatically use the relevant data characteristics.

```

See Poi (2004) for another example of residual resampling.

Saved results

bstat saves the following in e():

Scalars

e(N)	sample size
e(N_reps)	number of complete replications
e(N_misreps)	number of incomplete replications
e(N_strata)	number of strata
e(N_clust)	number of clusters
e(k_aux)	number of auxiliary parameters
e(k_eq)	number of equations in e(b)
e(k_exp)	number of standard expressions
e(k_eexp)	number of extended expressions (i.e., _b)
e(k_extra)	number of extra equations beyond the original ones from e(b)
e(level)	confidence level for bootstrap CIs
e(bs_version)	version for bootstrap results
e(rank)	rank of e(V)

Macros

e(cmd)	bstat
e(command)	from _dta[command]
e(cmdline)	command as typed
e(title)	title in estimation output
e(exp#)	expression for the #th statistic
e(prefix)	bootstrap
e(mse)	mse if specified
e(vce)	bootstrap
e(vcetype)	title used to label Std. Err.
e(properties)	b V

Matrices

e(b)	observed statistics
e(b_bs)	bootstrap estimates
e(reps)	number of nonmissing results
e(bias)	estimated biases
e(se)	estimated standard errors
e(z0)	median biases
e(accel)	estimated accelerations
e(ci_normal)	normal-approximation CIs
e(ci_percentile)	percentile CIs
e(ci_bc)	bias-corrected CIs
e(ci_bca)	bias-corrected and accelerated CIs
e(V)	bootstrap variance–covariance matrix

Methods and formulas

bstat is implemented as an ado-file.

Title

centile — Report centile and confidence interval

Syntax

`centile` [*varlist*] [*if*] [*in*] [`,` *options*]

options	Description
Main	
`centile(`*numlist*`)`	report specified centiles; default is `centile(50)`
Options	
`cci`	binomial exact; conservative confidence interval
`normal`	normal, based on observed centiles
`meansd`	normal, based on mean and standard deviation
`level(#)`	set confidence level; default is `level(95)`

`by` is allowed; see [D] **by**.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Centiles with CIs

Description

`centile` estimates specified centiles and calculates confidence intervals. If no *varlist* is specified, `centile` calculates centiles for all the variables in the dataset. If `centile()` is not specified, medians (`centile(50)`) are reported.

Options

Main

`centile(`*numlist*`)` specifies the centiles to be reported. The default is to display the 50th centile. Specifying `centile(5)` requests that the fifth centile be reported. Specifying `centile(5 50 95)` requests that the 5th, 50th, and 95th centiles be reported. Specifying `centile(10(10)90)` requests that the 10th, 20th, . . . , 90th centiles be reported; see [U] **11.1.8 numlist**.

Options

`cci` (conservative confidence interval) forces the confidence limits to fall exactly on sample values. Confidence intervals displayed with the `cci` option are slightly wider than those with the default (`nocci`) option.

`normal` causes the confidence interval to be calculated by using a formula for the standard error of a normal-distribution quantile given by Kendall and Stuart (1969, 237). The `normal` option is useful when you want empirical centiles—that is, centiles based on sample order statistics rather than on the mean and standard deviation—and are willing to assume normality.

`meansd` causes the centile and confidence interval to be calculated based on the sample mean and standard deviation, and it assumes normality.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] **level**.

Remarks

The qth centile of a continuous random variable, X, is defined as the value of C_q, which fulfills the condition $\Pr(X \leq C_q) = q/100$. The value of q must be in the range $0 < q < 100$, though q is not necessarily an integer. By default, `centile` estimates C_q for the variables in *varlist* and for the values of q given in `centile(`*numlist*`)`. It makes no assumptions about the distribution of X, and, if necessary, uses linear interpolation between neighboring sample values. Extreme centiles (for example, the 99th centile in samples smaller than 100) are fixed at the minimum or maximum sample value. An "exact" confidence interval for C_q is also given, using the binomial-based method described below in *Methods and formulas* and in Conover (1999, 143–148). Again linear interpolation is used to improve the accuracy of the estimated confidence limits, but extremes are fixed at the minimum or maximum sample value.

You can prevent `centile` from interpolating when calculating binomial-based confidence intervals by specifying `cci`. The resulting intervals are generally wider than with the default; that is, the coverage (confidence level) tends to be greater than the nominal value (given as usual by `level(#)`, by default 95%).

If the data are believed to be normally distributed (a common case), there are two alternative methods for estimating centiles. If `normal` is specified, C_q is calculated, as just described, but its confidence interval is based on a formula for the standard error (se) of a normal-distribution quantile given by Kendall and Stuart (1969, 237). If `meansd` is alternatively specified, C_q is estimated as $\overline{x} + z_q \times s$, where $\overline{x}$ and s are the sample mean and standard deviation, and z_q is the qth centile of the standard normal distribution (for example, $z_{95} = 1.645$). The confidence interval is derived from the se of the estimate of C_q.

▷ Example 1

Using `auto.dta`, we estimate the 5th, 50th, and 95th centiles of the `price` variable:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. format price %8.2fc
. centile price, centile(5 50 95)
```

Variable	Obs	Percentile	Centile	— Binom. Interp. — [95% Conf.	Interval]
price	74	5	3,727.75	3,291.23	3,914.16
		50	5,006.50	4,593.57	5,717.90
		95	13,498.00	11,061.53	15,865.30

`summarize` produces somewhat different results from `centile`; see *Methods and formulas*.

```
. summarize price, detail
```

Price

Percentiles		Smallest		
1%	3291	3291		
5%	3748	3299		
10%	3895	3667	Obs	74
25%	4195	3748	Sum of Wgt.	74
50%	5006.5		Mean	6165.257
		Largest	Std. Dev.	2949.496
75%	6342	13466		
90%	11385	13594	Variance	8699526
95%	13466	14500	Skewness	1.653434
99%	15906	15906	Kurtosis	4.819188

The confidence limits produced by using the `cci` option are slightly wider than those produced without this option:

```
. centile price, c(5 50 95) cci
```

Variable	Obs	Percentile	Centile	— Binomial Exact — [95% Conf.	Interval]
price	74	5	3,727.75	3,291.00	3,955.00
		50	5,006.50	4,589.00	5,719.00
		95	13,498.00	10,372.00	15,906.00

If we are willing to assume that `price` is normally distributed, we could include either the `normal` or the `meansd` option:

```
. centile price, c(5 50 95) normal
```

Variable	Obs	Percentile	— Normal, based on observed centiles — Centile	[95% Conf.	Interval]
price	74	5	3,727.75	3,211.19	4,244.31
		50	5,006.50	4,096.68	5,916.32
		95	13,498.00	5,426.81	21,569.19

```
. centile price, c(5 50 95) meansd
```

Variable	Obs	Percentile	— Normal, based on mean and std. dev.— Centile	[95% Conf.	Interval]
price	74	5	1,313.77	278.93	2,348.61
		50	6,165.26	5,493.24	6,837.27
		95	11,016.75	9,981.90	12,051.59

With the `normal` option, the centile estimates are, by definition, the same as before. The confidence intervals for the 5th and 50th centiles are similar to the previous ones, but the interval for the 95th centile is different. The results using the `meansd` option also differ from both previous sets of estimates.

We can use `sktest` (see [R] **sktest**) to check the correctness of the normality assumption:

```
. sktest price
```

Skewness/Kurtosis tests for Normality

Variable	Obs	Pr(Skewness)	Pr(Kurtosis)	joint adj chi2(2)	Prob>chi2
price	74	0.0000	0.0127	21.77	0.0000

sktest reveals that price is definitely not normally distributed, so the normal assumption is not reasonable, and the normal and meansd options are not appropriate for these data. We should rely on the results from the default choice, which does not assume normality. If the data are normally distributed, however, the precision of the estimated centiles and their confidence intervals will be ordered (best) meansd > normal > [default] (worst). The normal option is useful when we really do want empirical centiles (that is, centiles based on sample order statistics rather than on the mean and standard deviation) but are willing to assume normality.

◁

Saved results

centile saves the following in r():

Scalars

r(N)	number of observations
r(n_cent)	number of centiles requested
r(c_#)	value of # centile
r(lb_#)	#-requested centile lower confidence bound
r(ub_#)	#-requested centile upper confidence bound

Macros

r(centiles)	centiles requested

Methods and formulas

centile is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Default case
Normal case
meansd case

Default case

The calculation is based on the method of Mood and Graybill (1963, 408). Let $x_1 \leq x_2 \leq \cdots \leq x_n$ be a sample of size n arranged in ascending order. Denote the estimated qth centile of the x's as c_q. We require that $0 < q < 100$. Let $R = (n+1)q/100$ have integer part r and fractional part f; that is, $r = \text{int}(R)$ and $f = R - r$. (If R is itself an integer, then $r = R$ and $f = 0$.) Note that $0 \leq r \leq n$. For convenience, define $x_0 = x_1$ and $x_{n+1} = x_n$. C_q is estimated by

$$c_q = x_r + f \times (x_{r+1} - x_r)$$

that is, c_q is a weighted average of x_r and x_{r+1}. Loosely speaking, a (conservative) $p\%$ confidence interval for C_q involves finding the observations ranked t and u, which correspond, respectively, to the $\alpha = (100-p)/200$ and $1-\alpha$ quantiles of a binomial distribution with parameters n and $q/100$, that is, $\text{B}(n, q/100)$. More precisely, define the ith value ($i = 0, \ldots, n$) of the cumulative binomial distribution function as $F_i = \Pr(S \leq i)$, where S has distribution $\text{B}(n, q/100)$. For convenience, let $F_{-1} = 0$ and $F_{n+1} = 1$. t is found such that $F_t \leq \alpha$ and $F_{t+1} > \alpha$, and u is found such that $1 - F_u \leq \alpha$ and $1 - F_{u-1} > \alpha$.

With the cci option in force, the (conservative) confidence interval is (x_{t+1}, x_{u+1}), and its actual coverage probability is $F_u - F_t$.

The default case uses linear interpolation on the F_i as follows. Let

$$\begin{aligned} g &= (\alpha - F_t)/(F_{t+1} - F_t) \\ h &= \{\alpha - (1 - F_u)\}/\{(1 - F_{u-1}) - (1 - F_u)\} \\ &= (\alpha - 1 + F_u)/(F_u - F_{u-1}) \end{aligned}$$

The interpolated lower and upper confidence limits (c_{qL}, c_{qU}) for C_q are

$$\begin{aligned} c_{qL} &= x_{t+1} + g \times (x_{t+2} - x_{t+1}) \\ c_{qU} &= x_{u+1} - h \times (x_{u+1} - x_u) \end{aligned}$$

Suppose that we want a 95% confidence interval for the median of a sample of size 13. $n = 13$, $q = 50$, $p = 95$, $\alpha = 0.025$, $R = 14 \times 50/100 = 7$, and $f = 0$. Therefore, the median is the 7th observation. Some example data, x_i, and the values of F_i are as follows:

i	F_i	$1 - F_i$	x_i	i	F_i	$1 - F_i$	x_i
0	0.0001	0.9999	–	7	0.7095	0.2905	33
1	0.0017	0.9983	5	8	0.8666	0.1334	37
2	0.0112	0.9888	7	9	0.9539	0.0461	45
3	0.0461	0.9539	10	10	0.9888	0.0112	59
4	0.1334	0.8666	15	11	0.9983	0.0017	77
5	0.2905	0.7095	23	12	0.9999	0.0001	104
6	0.5000	0.5000	28	13	1.0000	0.0000	211

The median is $x_7 = 33$. Also, $F_2 \leq 0.025$ and $F_3 > 0.025$, so $t = 2$; $1 - F_{10} \leq 0.025$ and $1 - F_9 > 0.025$, so $u = 10$. The conservative confidence interval is therefore

$$(c_{50L}, c_{50U}) = (x_{t+1}, x_{u+1}) = (x_3, x_{11}) = (10, 77)$$

with actual coverage $F_{10} - F_2 = 0.9888 - 0.0112 = 0.9776$ (97.8% confidence). For the interpolation calculation, we have

$$\begin{aligned} g &= (0.025 - 0.0112)/(0.0461 - 0.0112) = 0.395 \\ h &= (0.025 - 1 + 0.9888)/(0.9888 - 0.9539) = 0.395 \end{aligned}$$

So,

$$\begin{aligned} c_{50L} &= x_3 + 0.395 \times (x_4 - x_3) = 10 + 0.395 \times 5 = 11.98 \\ c_{50U} &= x_{11} - 0.395 \times (x_{11} - x_{10}) = 77 - 0.395 \times 18 = 69.89 \end{aligned}$$

Normal case

The value of c_q is as above. Its se is given by the formula

$$s_q = \sqrt{q(100 - q)} \Big/ \Big\{100\sqrt{n} Z(c_q; \overline{x}, s)\Big\}$$

where $\overline{x}$ and s are the mean and standard deviation of the x_i, and

$$Z(Y; \mu, \sigma) = \Big(1/\sqrt{2\pi\sigma^2}\Big) e^{-(Y-\mu)^2/2\sigma^2}$$

is the density function of a normally distributed variable Y with mean μ and standard deviation σ. The confidence interval for C_q is $(c_q - z_{100(1-\alpha)} s_q, c_q + z_{100(1-\alpha)} s_q)$.

meansd case

The value of c_q is $\overline{x} + z_q \times s$. Its se is given by the formula

$$s_q^\star = s\sqrt{1/n + z_q^2/(2n-2)}$$

The confidence interval for C_q is $(c_q - z_{100(1-\alpha)} \times s_q^\star, c_q + z_{100(1-\alpha)} \times s_q^\star)$.

Acknowledgment

`centile` was written by Patrick Royston, MRC Clinical Trials Unit, London.

Title

ci — Confidence intervals for means, proportions, and counts

Syntax

Syntax for ci

`ci` [*varlist*] [*if*] [*in*] [*weight*] [`,` *options*]

Immediate command for variable distributed as normal

`cii` #$_{\text{obs}}$ #$_{\text{mean}}$ #$_{\text{sd}}$ [`,` *ciin_option*]

Immediate command for variable distributed as binomial

`cii` #$_{\text{obs}}$ #$_{\text{succ}}$ [`,` *ciib_options*]

Immediate command for variable distributed as Poisson

`cii` #$_{\text{exposure}}$ #$_{\text{events}}$ `, poisson` [*ciip_options*]

options	Description
Main	
`binomial`	binomial 0/1 variables; compute exact confidence intervals
`poisson`	Poisson variables; compute exact confidence intervals
`exposure(`*varname*`)`	exposure variable; implies `poisson`
`exact`	calculate exact confidence intervals; the default
`wald`	calculate Wald confidence intervals
`wilson`	calculate Wilson confidence intervals
`agresti`	calculate Agresti–Coull confidence intervals
`jeffreys`	calculate Jeffreys confidence intervals
`total`	add output for all groups combined (for use with `by` only)
`separator(#)`	draw separator line after every # variables; default is `separator(5)`
`level(#)`	set confidence level; default is `level(95)`

`by` is allowed with `ci`; see [D] **by**.

`aweights` and `fweights` are allowed, but `aweights` may not be specified with the `binomial` or `poisson` options; see [U] **11.1.6 weight**.

ciin_option	Description
`level(#)`	set confidence level; default is `level(95)`

ciib_options	Description
level(#)	set confidence level; default is level(95)
exact	calculate exact confidence intervals; the default
wald	calculate Wald confidence intervals
wilson	calculate Wilson confidence intervals
agresti	calculate Agresti–Coull confidence intervals
jeffreys	calculate Jeffreys confidence intervals

ciip_options	Description
*poisson	numbers are Poisson-distributed counts
level(#)	set confidence level; default is level(95)

*poisson is required.

cii for variable distributed as binomial

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Binomial CI calculator

cii for variable distributed as Poisson

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Poisson CI calculator

Description

ci computes standard errors and confidence intervals for each of the variables in *varlist*.

cii is the immediate form of ci; see [U] **19 Immediate commands** for a general discussion of immediate commands.

In the binomial and Poisson variants of cii, the second number specified ($\#_{\text{succ}}$ or $\#_{\text{events}}$) must be an integer or between 0 and 1. If the number is between 0 and 1, Stata interprets it as the fraction of successes or events and converts it to an integer number representing the number of successes or events. The computation then proceeds as if two integers had been specified.

Options

Main

binomial tells ci that the variables are 0/1 variables and that binomial confidence intervals will be calculated. (cii produces binomial confidence intervals when only two numbers are specified.)

`poisson` specifies that the variables (or numbers for `cii`) are Poisson-distributed counts; exact Poisson confidence intervals will be calculated.

`exposure(`*varname*`)` is used only with `poisson`. You do not need to specify `poisson` if you specify `exposure()`; `poisson` is assumed. *varname* contains the total exposure (typically a time or an area) during which the number of events recorded in *varlist* were observed.

`exact`, `wald`, `wilson`, `agresti`, and `jeffreys` specify that variables are 0/1 and specify how binomial confidence intervals are to be calculated.

`exact` is the default and specifies exact (also known in the literature as Clopper–Pearson [1934]) binomial confidence intervals.

`wald` specifies calculation of Wald confidence intervals.

`wilson` specifies calculation of Wilson confidence intervals.

`agresti` specifies calculation of Agresti–Coull confidence intervals.

`jeffreys` specifies calculation of Jeffreys confidence intervals.

See Brown, Cai, and DasGupta (2001) for a discussion and comparison of the different binomial confidence intervals.

`total` is for use with the `by` prefix. It requests that, in addition to output for each by-group, output be added for all groups combined.

`separator(#)` specifies how often separation lines should be inserted into the output. The default is `separator(5)`, meaning that a line is drawn after every five variables. `separator(10)` would draw the line after every 10 variables. `separator(0)` suppresses the separation line.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] **level**.

Remarks

Remarks are presented under the following headings:

Ordinary confidence intervals
Binomial confidence intervals
Poisson confidence intervals
Immediate form

Ordinary confidence intervals

▷ Example 1

Without the `binomial` or `poisson` options, `ci` produces "ordinary" confidence intervals, meaning those that are correct if the variable is distributed normally, and *asymptotically* correct for all other distributions satisfying the conditions of the central limit theorem.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ci mpg price
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+--------------------------------------------------------------
         mpg |         74     21.2973    .6725511        19.9569    22.63769
       price |         74    6165.257    342.8719        5481.914      6848.6
```

The standard error of the mean of mpg is 0.67, and the 95% confidence interval is [19.96, 22.64]. We can obtain wider confidence intervals, 99%, by typing

```
. ci mpg price, level(99)
    Variable |        Obs        Mean    Std. Err.       [99% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         74     21.2973    .6725511        19.51849    23.07611
       price |         74    6165.257    342.8719        5258.405    7072.108
```

◁

▷ Example 2

by() breaks out the confidence intervals according to by-group; total adds an overall summary. For instance,

```
. ci mpg, by(foreign) total
-------------------------------------------------------------------------------
-> foreign = Domestic
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         52    19.82692     .657777        18.50638    21.14747
-------------------------------------------------------------------------------
-> foreign = Foreign
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         22    24.77273     1.40951        21.84149    27.70396
-------------------------------------------------------------------------------
-> Total
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         74     21.2973    .6725511         19.9569    22.63769
```

◁

❑ Technical note

You can control the formatting of the numbers in the output by specifying a display format for the variable; see [U] **12.5 Formats: Controlling how data are displayed**. For instance,

```
. format mpg %9.2f
. ci mpg
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         74       21.30        0.67           19.96       22.64
```

❑

Binomial confidence intervals

▷ Example 3

We have data on employees, including a variable marking whether the employee was promoted last year.

```
. use http://www.stata-press.com/data/r12/promo
. ci promoted, binomial
```

Variable	Obs	Mean	Std. Err.	— Binomial Exact — [95% Conf.	Interval]
promoted	20	.1	.067082	.0123485	.3169827

The above interval is the default for binomial data, known equivalently as both the exact binomial and the Clopper–Pearson interval.

Nominally, the interpretation of a 95% confidence interval is that under repeated samples or experiments, 95% of the resultant intervals would contain the unknown parameter in question. However, for binomial data, the actual coverage probability, regardless of method, usually differs from that interpretation. This result occurs because of the discreteness of the binomial distribution, which produces only a finite set of outcomes, meaning that coverage probabilities are subject to discrete jumps and the exact nominal level cannot always be achieved. Therefore, the term *exact confidence interval* refers to its being derived from the binomial distribution, the distribution exactly generating the data, rather than resulting in exactly the nominal coverage.

For the Clopper–Pearson interval, the actual coverage probability is guaranteed to be greater than or equal to the nominal confidence level, here 95%. Because of the way it is calculated—see *Methods and formulas*—it may also be interpreted as follows: If the true probability of being promoted were 0.012, the chances of observing a result as extreme or more extreme than the result observed ($20 \times 0.1 = 2$ or more promotions) would be 2.5%. If the true probability of being promoted were 0.317, the chances of observing a result as extreme or more extreme than the result observed (two or fewer promotions) would be 2.5%.

◁

▷ Example 4

The Clopper–Pearson interval is desirable because it guarantees nominal coverage; however, by dropping this restriction, you may obtain accurate intervals that are not as conservative. In this vein, you might opt for the Wilson (1927) interval,

```
. ci promoted, binomial wilson
```

Variable	Obs	Mean	Std. Err.	——— Wilson ——— [95% Conf.	Interval]
promoted	20	.1	.067082	.0278665	.3010336

the Agresti–Coull (1998) interval,

```
. ci promoted, binomial agresti
```

Variable	Obs	Mean	Std. Err.	— Agresti-Coull — [95% Conf.	Interval]
promoted	20	.1	.067082	.0156562	.3132439

or the Bayesian-derived Jeffreys interval (Brown, Cai, and DasGupta 2001),

```
. ci promoted, binomial jeffreys
```

Variable	Obs	Mean	Std. Err.	——— Jeffreys ——— [95% Conf.	Interval]
promoted	20	.1	.067082	.0213725	.2838533

Picking the best interval is a matter of balancing accuracy (coverage) against precision (average interval length) and depends on sample size and success probability. Brown, Cai, and DasGupta (2001) recommend the Wilson or Jeffreys interval for small sample sizes ($\leq$40) yet favor the Agresti–Coull interval for its simplicity, decent performance for sample sizes less than or equal to 40, and performance comparable to Wilson/Jeffreys for sample sizes greater than 40. They also deem the Clopper–Pearson interval to be "wastefully conservative and [. . .] not a good choice for practical use", unless of course one requires, at a minimum, the nominal coverage level.

◁

Finally, the binomial Wald confidence interval is obtained by specifying the `binomial` and `wald` options. The Wald interval is the one taught in most introductory statistics courses and for the above is simply, for level $1-\alpha$, `Mean`$\pm z_\alpha$(`Std. Err.`), where z_α is the $1-\alpha/2$ quantile of the standard normal. Because its overall poor performance makes it impractical, the Wald interval is available mainly for pedagogical purposes. The binomial Wald interval is also similar to the interval produced by treating binary data as normal data and using `ci` without the `binomial` option, with two exceptions. First, when `binomial` is specified, the calculation of the standard error uses denominator n rather than $n-1$, used for normal data. Second, confidence intervals for normal data are based on the t distribution rather than the standard normal. Of course, both discrepancies vanish as sample size increases.

❑ Technical note

Let's repeat example 3, but this time with data in which there are no promotions over the observed period:

```
. use http://www.stata-press.com/data/r12/promonone
. ci promoted, binomial
                                                      — Binomial Exact —
    Variable |       Obs        Mean    Std. Err.     [95% Conf. Interval]
-------------+--------------------------------------------------------------
    promoted |        20           0           0                0    .1684335*
(*) one-sided, 97.5% confidence interval
```

The confidence interval is $[0, 0.168]$, and this is the confidence interval that most books publish. It is not, however, a true 95% confidence interval because the lower tail has vanished. As Stata notes, it is a one-sided, 97.5% confidence interval. If you wanted to put 5% in the right tail, you could type `ci promoted, binomial level(90)`.

❑

❑ Technical note

`ci` with the `binomial` option ignores any variables that do not take on the values 0 and 1 exclusively. For instance, with our automobile dataset,

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ci mpg foreign, binomial
                                                      — Binomial Exact —
    Variable |       Obs        Mean    Std. Err.     [95% Conf. Interval]
-------------+--------------------------------------------------------------
     foreign |        74    .2972973    .0531331      .196584    .4148353
```

We also requested the confidence interval for `mpg`, but Stata ignored us. It does that so you can type `ci, binomial` and obtain correct confidence intervals for all the variables that are 0/1 in your data.

❑

Poisson confidence intervals

▷ Example 5

We have data on the number of bacterial colonies on a Petri dish. The dish has been divided into 36 small squares, and the number of colonies in each square has been counted. Each observation in our dataset represents a square on the dish. The variable `count` records the number of colonies in each square counted, which varies from 0 to 5.

```
. use http://www.stata-press.com/data/r12/petri
. ci count, poisson
```

Variable	Exposure	Mean	Std. Err.	— Poisson Exact — [95% Conf.	Interval]
count	36	2.333333	.2545875	1.861158	2.888825

`ci` reports that the average number of colonies per square is 2.33. If the expected number of colonies per square were as low as 1.86, the probability of observing 2.33 or more colonies per square would be 2.5%. If the expected number were as large as 2.89, the probability of observing 2.33 or fewer colonies per square would be 2.5%.

◁

❑ Technical note

The number of "observations"—how finely the Petri dish is divided—makes no difference. The Poisson distribution is a function only of the count. In example 4, we observed a total of $2.33 \times 36 = 84$ colonies and a confidence interval of $[\,1.86 \times 36, 2.89 \times 36\,] = [\,67, 104\,]$. We would obtain the same $[\,67, 104\,]$ confidence interval if our dish were divided into, say, 49 squares, rather than 36.

For the counts, it is not even important that all the squares be of the same size. For *rate*s, however, such differences do matter, but in an easy-to-calculate way. Rates are obtained from counts by dividing by exposure, which is typically a number multiplied by either time or an area. For our Petri dishes, we divide by an area to obtain a rate, but if our example were cast in terms of being infected by a disease, we might divide by person-years to obtain the rate. Rates are convenient because they are easier to compare: we might have 2.3 colonies per square inch or 0.0005 infections per person-year.

So, let's assume that we wish to obtain the number of colonies per square inch, and, moreover, that not all the "squares" on our dish are of equal size. We have a variable called `area` that records the area of each "square":

```
. ci count, exposure(area)
```

Variable	Exposure	Mean	Std. Err.	— Poisson Exact — [95% Conf.	Interval]
count	3	28	3.055051	22.3339	34.66591

The rates are now in more familiar terms. In our sample, there are 28 colonies per square inch and the 95% confidence interval is $[\,22.3, 34.7\,]$. When we did not specify `exposure()`, `ci` assumed that each observation contributed 1 to exposure.

❑

❑ Technical note

As with the binomial option, if there were no colonies on our dish, ci would calculate a one-sided confidence interval:

```
. use http://www.stata-press.com/data/r12/petrinone
. ci count, poisson
```

Variable	Exposure	Mean	Std. Err.	— Poisson Exact — [95% Conf.	Interval]
count	36	0	0	0	.1024689*

(*) one-sided, 97.5% confidence interval

❑

Immediate form

▷ Example 6

We are reading a soon-to-be-published paper by a colleague. In it is a table showing the number of observations, mean, and standard deviation of 1980 median family income for the Northeast and West. We correctly think that the paper would be much improved if it included the confidence intervals. The paper claims that for 166 cities in the Northeast, the average of median family income is $19,509 with a standard deviation of $4,379:

For the Northeast:

```
. cii 166 19509 4379
```

Variable	Obs	Mean	Std. Err.	[95% Conf.	Interval]
	166	19509	339.8763	18837.93	20180.07

For the West:

```
. cii 256 22557 5003
```

Variable	Obs	Mean	Std. Err.	[95% Conf.	Interval]
	256	22557	312.6875	21941.22	23172.78

◁

▷ Example 7

We flip a coin 10 times, and it comes up heads only once. We are shocked and decide to obtain a 99% confidence interval for this coin:

```
. cii 10 1, level(99)
```

Variable	Obs	Mean	Std. Err.	— Binomial Exact — [99% Conf.	Interval]
	10	.1	.0948683	.0005011	.5442871

◁

▷ Example 8

The number of reported traffic accidents in Santa Monica over a 24-hour period is 27. We need know nothing else:

```
. cii 1 27, poisson
```

Variable	Exposure	Mean	Std. Err.	— Poisson Exact — [95% Conf. Interval]	
	1	27	5.196152	17.79317	39.28358

◁

Saved results

`ci` and `cii` saves the following in `r()`:

Scalars

`r(N)`	number of observations or exposure	`r(lb)`	lower bound of confidence interval
`r(mean)`	mean	`r(ub)`	upper bound of confidence interval
`r(se)`	estimate of standard error		

Methods and formulas

`ci` and `cii` are implemented as ado-files.

Methods and formulas are presented under the following headings:

Ordinary
Binomial
Poisson

Ordinary

Define n, $\overline{x}$, and s^2 as, respectively, the number of observations, (weighted) average, and (unbiased) estimated variance of the variable in question; see [R] **summarize**.

The standard error of the mean, s_μ, is defined as $\sqrt{s^2/n}$.

Let α be $1 - l/100$, where l is the significance level specified by the user. Define t_α as the two-sided t statistic corresponding to a significance level of α with $n-1$ degrees of freedom; t_α is obtained from Stata as `invttail(`n`-1,0.5*`α`)`. The lower and upper confidence bounds are, respectively, $\overline{x} - s_\mu t_\alpha$ and $\overline{x} + s_\mu t_\alpha$.

Binomial

Given k successes of n trials, the estimated probability is $\widehat{p} = k/n$ with standard error $\sqrt{\widehat{p}(1-\widehat{p})/n}$. `ci` calculates the exact (Clopper–Pearson) confidence interval $[\,p_1, p_2\,]$ such that

$$\Pr(K \geq k | p = p_1) = \alpha/2$$

and

$$\Pr(K \leq k | p = p_2) = \alpha/2$$

where K is distributed as binomial(n, p). The endpoints may be obtained directly by using Stata's `invbinomial()` function. If $k = 0$ or $k = n$, the calculation of the appropriate tail is skipped.

The Wald interval is $\widehat{p} \pm z_\alpha \sqrt{\widehat{p}(1-\widehat{p})/n}$, where z_α is the $1 - \alpha/2$ quantile of the standard normal. The interval is obtained by inverting the acceptance region of the large-sample Wald test of $H_0 : p = p_0$ versus the two-sided alternative. That is, the confidence interval is the set of all p_0 such that

$$\left| \frac{\widehat{p} - p_0}{\sqrt{n^{-1}\widehat{p}(1-\widehat{p})}} \right| \leq z_\alpha$$

The Wilson interval is a variation on the Wald interval, using the null standard error $\sqrt{n^{-1}p_0(1-p_0)}$ in place of the estimated standard error $\sqrt{n^{-1}\widehat{p}(1-\widehat{p})}$ in the above expression. Inverting this acceptance region is more complicated yet results in the closed form

$$\frac{k + z_\alpha^2/2}{n + z_\alpha^2} \pm \frac{z_\alpha n^{1/2}}{n + z_\alpha^2/2} \left\{ \widehat{p}(1-\widehat{p}) + \frac{z_\alpha^2}{4n} \right\}^{1/2}$$

The Agresti–Coull interval is basically a Wald interval that borrows its center from the Wilson interval. Defining $\widetilde{k} = k + z_\alpha^2/2$, $\widetilde{n} = n + z_\alpha^2$, and (hence) $\widetilde{p} = \widetilde{k}/\widetilde{n}$, the Agresti–Coull interval is

$$\widetilde{p} \pm z_\alpha \sqrt{\widetilde{p}(1-\widetilde{p})/\widetilde{n}}$$

When $\alpha = 0.05$, z_α is near enough to 2 that $\widetilde{p}$ can be thought of as a typical estimate of proportion where two successes and two failures have been added to the sample (Agresti and Coull 1998). This typical estimate of proportion makes the Agresti–Coull interval an easy-to-present alternative for introductory statistics students.

The Jeffreys interval is a Bayesian interval and is based on the Jeffreys prior, which is the Beta$(1/2, 1/2)$ distribution. Assigning this prior to p results in a posterior distribution for p that is Beta with parameters $k+1/2$ and $n-k+1/2$. The Jeffreys interval is then taken to be the $1-\alpha$ central posterior probability interval, namely, the $\alpha/2$ and $1-\alpha/2$ quantiles of the Beta$(k+1/2, n-k+1/2)$ distribution. These quantiles may be obtained directly by using Stata's `invibeta()` function.

Poisson

Given the total cases, k, the estimate of the expected count λ is k, and its standard error is $\sqrt{k}$. `ci` calculates the exact confidence interval $[\lambda_1, \lambda_2]$ such that

$$\Pr(K \geq k | \lambda = \lambda_1) = \alpha/2$$

and

$$\Pr(K \leq k | \lambda = \lambda_2) = \alpha/2$$

where K is Poisson with mean λ. Solution is by Newton's method. If $k = 0$, the calculation of λ_1 is skipped. All values are then reported as rates, which are the above numbers divided by the total exposure.

Harold Jeffreys (1891–1989) was born near Durham, England, and spent more than 75 years studying and working at the University of Cambridge, principally on theoretical and observational problems in geophysics, astronomy, mathematics, and statistics. He developed a systematic Bayesian approach to inference in his monograph *Theory of Probability*.

Edwin Bidwell (E. B.) Wilson (1879–1964) majored in mathematics at Harvard and studied and taught at Yale and MIT before returning to Harvard in 1922. He worked in mathematics, physics, and statistics. His method for binomial intervals can be considered a precursor, for a particular problem, of Neyman's concept of confidence intervals.

Jerzy Neyman (1894–1981) was born in Bendery, Russia, now Moldavia. He studied and then taught at Kharkov University, moving from physics to mathematics. In 1921, Neyman moved to Poland, where he worked in statistics at Bydgoszcz and then Warsaw. Neyman received a Rockefeller Fellowship to work with Karl Pearson at University College London. There, he collaborated with Egon Pearson, Karl's son, on the theory of hypothesis testing. Life in Poland became progressively more difficult, and Neyman returned to UCL to work there from 1934 to 1938. At this time, he published on the theory of confidence intervals. He then was offered a post in California at Berkeley, where he settled. Neyman established an outstanding statistics department and remained highly active in research, including applications in astronomy, meteorology, and medicine. He was one of the great statisticians of the 20th century.

Acknowledgment

We thank Nicholas J. Cox of Durham University for his assistance with the `jeffreys` and `wilson` options.

Title

clogit — Conditional (fixed-effects) logistic regression

Syntax

`clogit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] , `group(`*varname*`)` [*options*]

options	Description
Model	
* `group(`*varname*`)`	matched group variable
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
`nonest`	do not check that panels are nested within clusters
Reporting	
`level(`#`)`	set confidence level; default is `level(95)`
`or`	report odds ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

*`group(`*varname*`)` is required.

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `nonest`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed (see [U] **11.1.6 weight**), but they are interpreted to apply to groups as a whole, not to individual observations. See *Use of weights* below.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Categorical outcomes > Conditional logistic regression

Description

`clogit` fits what biostatisticians and epidemiologists call conditional logistic regression for matched case–control groups (see, for example, Hosmer and Lemeshow [2000, chap. 7]) and what economists and other social scientists call fixed-effects logit for panel data (see, for example, Chamberlain [1980]). Computationally, these models are the same. *depvar* equal to nonzero and nonmissing (typically *depvar* equal to one) indicates a positive outcome, whereas *depvar* equal to zero indicates a negative outcome.

See [R] **asclogit** if you want to fit McFadden's choice model (McFadden 1974). Also see [R] **logistic** for a list of related estimation commands.

Options

Model

`group(`*varname*`)` is required; it specifies an identifier variable (numeric or string) for the matched groups. `strata(`*varname*`)` is a synonym for `group()`.

`offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`nonest`, available only with `vce(cluster` *clustvar*`)`, prevents checking that matched groups are nested within clusters. It is the user's responsibility to verify that the standard errors are theoretically correct.

Reporting

`level(#)`; see [R] **estimation options**.

`or` reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `clogit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Matched case–control data
Use of weights
Fixed-effects logit

Introduction

`clogit` fits maximum likelihood models with a dichotomous dependent variable coded as 0/1 (more precisely, `clogit` interprets 0 and not 0 to indicate the dichotomy). Conditional logistic analysis differs from regular logistic regression in that the data are grouped and the likelihood is calculated relative to each group; that is, a conditional likelihood is used. See *Methods and formulas* at the end of this entry.

Biostatisticians and epidemiologists fit these models when analyzing matched case–control studies with $1:1$ matching, $1:k_{2i}$ matching, or $k_{1i}:k_{2i}$ matching, where i denotes the ith matched group for $i = 1, 2, \ldots, n$, where n is the total number of groups. `clogit` fits a model appropriate for all these matching schemes or for any mix of the schemes because the matching $k_{1i}:k_{2i}$ can vary from group to group. `clogit` always uses the true conditional likelihood, not an approximation. Biostatisticians and epidemiologists sometimes refer to the matched groups as "strata", but we will stick to the more generic term "group".

Economists and other social scientists fitting fixed-effects logit models have data that look exactly like the data biostatisticians and epidemiologists call $k_{1i}:k_{2i}$ matched case–control data. In terms of how the data are arranged, $k_{1i}:k_{2i}$ matching means that in the ith group, the dependent variable is 1 a total of k_{1i} times and 0 a total of k_{2i} times. There are a total of $T_i = k_{1i} + k_{2i}$ observations for the ith group. This data arrangement is what economists and other social scientists call "panel data", "longitudinal data", or "cross-sectional time-series data".

So no matter what terminology you use, the computation and the use of the `clogit` command is the same. The following example shows how your data should be arranged to use `clogit`.

▷ Example 1

Suppose that we have grouped data with the variable `id` containing a unique identifier for each group. Our outcome variable, `y`, contains 0s and 1s. If we were biostatisticians, `y` = 1 would indicate a case, `y` = 0 would be a control, and `id` would be an identifier variable that indicates the groups of matched case–control subjects.

If we were economists, `y` = 1 might indicate that a person was unemployed at any time during a year and `y` = 0, that a person was employed all year, and `id` would be an identifier variable for persons.

If we list the first few observations of this dataset, it looks like

```
. use http://www.stata-press.com/data/r12/clogitid
. list y x1 x2 id in 1/11
```

	y	x1	x2	id
1.	0	0	4	1014
2.	0	1	4	1014
3.	0	1	6	1014
4.	1	1	8	1014
5.	0	0	1	1017
6.	0	0	7	1017
7.	1	1	10	1017
8.	0	0	1	1019
9.	0	1	7	1019
10.	1	1	7	1019
11.	1	1	9	1019

Pretending that we are biostatisticians, we describe our data as follows. The first group (`id` $= 1014$) consists of four matched persons: 1 case (`y` $= 1$) and three controls (`y` $= 0$), that is, $1:3$ matching. The second group has $1:2$ matching, and the third $2:2$.

Pretending that we are economists, we describe our data as follows. The first group consists of 4 observations (one per year) for person 1014. This person had a period of unemployment during 1 year of 4. The second person had a period of unemployment during 1 year of 3, and the third had a period of 2 years of 4.

Our independent variables are `x1` and `x2`. To fit the conditional (fixed-effects) logistic model, we type

```
. clogit y x1 x2, group(id)
note: multiple positive outcomes within groups encountered.
Iteration 0:   log likelihood = -123.42828
Iteration 1:   log likelihood = -123.41386

```

◁

❑ Technical note

The message "note: multiple positive outcomes within groups encountered" at the top of the `clogit` output for the previous example merely informs us that we have $k_{1i} : k_{2i}$ matching with $k_{1i} > 1$ for at least one group. If your data should be $1 : k_{2i}$ matched, this message tells you that there is an error in the data somewhere.

We can see the distribution of k_{1i} and $T_i = k_{1i} + k_{2i}$ for the data of the previous example by using the following steps:

```
. by id, sort: gen k1 = sum(y)
. by id: replace k1 = . if _n < _N
(303 real changes made, 303 to missing)
. by id: gen T = sum(y < .)
. by id: replace T = . if _n < _N
(303 real changes made, 303 to missing)
. tab k1
```

k1	Freq.	Percent	Cum.
1	48	72.73	72.73
2	12	18.18	90.91
3	4	6.06	96.97
4	2	3.03	100.00
Total	66	100.00	

```
. tab T
```

T	Freq.	Percent	Cum.
2	5	7.58	7.58
3	5	7.58	15.15
4	12	18.18	33.33
5	11	16.67	50.00
6	13	19.70	69.70
7	8	12.12	81.82
8	3	4.55	86.36
9	7	10.61	96.97
10	2	3.03	100.00
Total	66	100.00	

We see that k_{1i} ranges from 1 to 4 and T_i ranges from 2 to 10 for these data.

❑

❑ Technical note

For $k_{1i} : k_{2i}$ matching (and hence in the general case of fixed-effects logit), `clogit` uses a recursive algorithm to compute the likelihood, which means that there are no limits on the size of T_i. However, computation time is proportional to $\sum T_i \min(k_{1i}, k_{2i})$, so `clogit` will take roughly 10 times longer to fit a model with 10 : 10 matching than one with 1 : 10 matching. But `clogit` is fast, so computation time becomes an issue only when $\min(k_{1i}, k_{2i})$ is around 100 or more. See *Methods and formulas* for details.

❑

Matched case–control data

Here we give a more detailed example of matched case−control data.

▷ Example 2

Hosmer and Lemeshow (2000, 25) present data on matched pairs of infants, each pair having one with low birthweight and another with regular birthweight. The data are matched on age of the mother. Several possible maternal exposures are considered: race (three categories), smoking status, presence of hypertension, presence of uterine irritability, previous preterm delivery, and weight at the last menstrual period.

```

------------------------------------------------------------------------------
```

Smoking, previous preterm delivery, hypertension, uterine irritability, and possibly the mother's weight all contribute to low birthweight. `2.race` (mother black) and `3.race` (mother other) are statistically insignificant when compared with the `1.race` (mother white) omitted group, although the `2.race` effect is large. We can test the joint statistical significance of `2.race` and `3.race` by using `test`:

```
. test 2.race 3.race
 ( 1)  [low]2.race = 0
 ( 2)  [low]3.race = 0

           chi2(  2) =    0.88
         Prob > chi2 =    0.6436
```

For a more complete description of `test`, see [R] **test**. `test` presents results in coefficients rather than odds ratios. Jointly testing that the coefficients on `2.race` and `3.race` are 0 is equivalent to jointly testing that the odds ratios are 1.

Here one case was matched to one control, that is, 1:1 matching. From `clogit`'s point of view, that was not important—k_1 cases could have been matched to k_2 controls ($k_1 : k_2$ matching), and we would have fit the model in the same way. Furthermore, the matching can change from group to group, which we have denoted as $k_{1i} : k_{2i}$ matching, where i denotes the group. `clogit` does not care. To fit the conditional logistic regression model, we specified the `group(`*varname*`)` option, `group(pairid)`. The case and control are stored in separate observations. `clogit` knew that they were linked (in the same group) because the related observations share the same value of `pairid`.

◁

❑ Technical note

`clogit` provides a way to extend McNemar's test to multiple controls per case ($1 : k_{2i}$ matching) and to multiple controls matched with multiple cases ($k_{1i} : k_{2i}$ matching).

In Stata, McNemar's test is calculated by the `mcc` command; see [ST] **epitab**. The `mcc` command, however, requires that the matched case and control appear in one observation, so the data will need to be manipulated from 1 to 2 observations per stratum before using `clogit`. Alternatively, if you begin with `clogit`'s 2-observations-per-group organization, you will have to change it to 1 observation per group if you wish to use `mcc`. In either case, `reshape` provides an easy way to change the organization of the data. We will demonstrate its use below, but we direct you to [D] **reshape** for a more thorough discussion.

In the example above, we used `clogit` to analyze the relationship between low birthweight and various characteristics of the mother. Assume that we now want to assess the relationship between low birthweight and smoking, ignoring the mother's other characteristics. Using `clogit`, we obtain the following results:

```
. clogit low smoke, group(pairid) or
Iteration 0:   log likelihood = -35.425931
Iteration 1:   log likelihood = -35.419283
Iteration 2:   log likelihood = -35.419282
Conditional (fixed-effects) logistic regression   Number of obs   =        112
                                                  LR chi2(1)      =       6.79
                                                  Prob > chi2     =     0.0091
Log likelihood = -35.419282                       Pseudo R2       =     0.0875
------------------------------------------------------------------------------
         low | Odds Ratio   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       smoke |        2.75   1.135369     2.45   0.014     1.224347    6.176763
------------------------------------------------------------------------------
```

Let's compare our estimated odds ratio and 95% confidence interval with that produced by `mcc`. We begin by reshaping the data:

```
. keep low smoke pairid
. reshape wide smoke, i(pairid) j(low 0 1)
Data                               long   ->   wide
-----------------------------------------------------------------------------
Number of obs.                      112   ->     56
Number of variables                   3   ->      3
j variable (2 values)               low   ->   (dropped)
xij variables:
                                  smoke   ->   smoke0 smoke1
-----------------------------------------------------------------------------
```

We now have the variables `smoke0` (formed from `smoke` and `low` = 0), recording 1 if the control mother smoked and 0 otherwise; and `smoke1` (formed from `smoke` and `low` = 1), recording 1 if the case mother smoked and 0 otherwise. We can now use `mcc`:

```
. mcc smoke1 smoke0
```

Cases	Controls Exposed	Unexposed	Total
Exposed	8	22	30
Unexposed	8	18	26
Total	16	40	56

```
McNemar's chi2(1) =      6.53    Prob > chi2 = 0.0106
Exact McNemar significance probability       = 0.0161

Proportion with factor
        Cases       .5357143
        Controls    .2857143     [95% Conf. Interval]
        ---------   ---------    --------------------
        difference        .25      .0519726   .4480274
        ratio            1.875     1.148685   3.060565
        rel. diff.         .35      .1336258   .5663742
        odds ratio        2.75      1.179154   7.143667   (exact)
```

Both methods estimated the same odds ratio, and the 95% confidence intervals are similar. `clogit` produced a confidence interval of $[1.22, 6.18]$, whereas `mcc` produced a confidence interval of $[1.18, 7.14]$.

❑

Use of weights

With `clogit`, weights apply to groups as a whole, not to individual observations. For example, if there is a group in your dataset with a frequency weight of 3, there are a total of three groups in your sample with the same values of the dependent and independent variables as this one group. Weights must have the same value for all observations belonging to the same group; otherwise, an error message will be displayed.

▷ Example 3

We use the example from the above discussion of the `mcc` command. Here we have a total of 56 matched case–control groups, each with one case matched to one control. We had 8 matched pairs in which both the case and the control are exposed, 22 pairs in which the case is exposed and the control is unexposed, 8 pairs in which the case is unexposed and the control is exposed, and 18 pairs in which they are both unexposed.

With weights, it is easy to enter these data into Stata and run `clogit`.

```
. clear
. input id case exposed weight
           id       case    exposed     weight
  1. 1 1 1 8
  2. 1 0 1 8
  3. 2 1 1 22
  4. 2 0 0 22
  5. 3 1 0 8
  6. 3 0 1 8
  7. 4 1 0 18
  8. 4 0 0 18
  9. end
. clogit case exposed [w=weight], group(id) or
(frequency weights assumed)
Iteration 0:   log likelihood = -35.425931
Iteration 1:   log likelihood = -35.419283
Iteration 2:   log likelihood = -35.419282
Conditional (fixed-effects) logistic regression   Number of obs   =        112
                                                  LR chi2(1)      =       6.79
                                                  Prob > chi2     =     0.0091
Log likelihood = -35.419282                       Pseudo R2       =     0.0875
```

case	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
exposed	2.75	1.135369	2.45	0.014	1.224347	6.176763

Fixed-effects logit

The fixed-effects logit model can be written as

$$\Pr(y_{it} = 1 \mid \mathbf{x}_{it}) = F(\alpha_i + \mathbf{x}_{it}\boldsymbol{\beta})$$

where F is the cumulative logistic distribution

$$F(z) = \frac{\exp(z)}{1 + \exp(z)}$$

$i = 1, 2, \ldots, n$ denotes the independent units (called "groups" by `clogit`), and $t = 1, 2, \ldots, T_i$ denotes the observations for the ith unit (group).

Fitting this model by using a full maximum-likelihood approach leads to difficulties, however. When T_i is fixed, the maximum likelihood estimates for α_i and $\boldsymbol{\beta}$ are inconsistent (Andersen 1970; Chamberlain 1980). This difficulty can be circumvented by looking at the probability of $\mathbf{y}_i = (y_{i1}, \ldots, y_{iT_i})$ conditional on $\sum_{t=1}^{T_i} y_{it}$. This conditional probability does not involve the α_i, so they are never estimated when the resulting conditional likelihood is used. See Hamerle and Ronning (1995) for a succinct and lucid development. See *Methods and formulas* for the estimation equation.

▷ Example 4

We are studying unionization of women in the United States by using the `union` dataset; see [XT] **xt**. We fit the fixed-effects logit model:

```
. use http://www.stata-press.com/data/r12/union, clear
(NLS Women 14-24 in 1968)
. clogit union age grade not_smsa south black, group(idcode)
note: multiple positive outcomes within groups encountered.
note: 2744 groups (14165 obs) dropped because of all positive or
      all negative outcomes.
note: black omitted because of no within-group variance.
Iteration 0:   log likelihood = -4521.3385
Iteration 1:   log likelihood = -4516.1404
Iteration 2:   log likelihood = -4516.1385
Iteration 3:   log likelihood = -4516.1385
Conditional (fixed-effects) logistic regression   Number of obs   =      12035
                                                  LR chi2(4)      =      68.09
                                                  Prob > chi2     =     0.0000
Log likelihood = -4516.1385                       Pseudo R2       =     0.0075
```

union	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.0170301	.004146	4.11	0.000	.0089042	.0251561
grade	.0853572	.0418781	2.04	0.042	.0032777	.1674368
not_smsa	.0083678	.1127963	0.07	0.941	-.2127088	.2294445
south	-.748023	.1251752	-5.98	0.000	-.9933619	-.5026842
black	0	(omitted)				

We received three messages at the top of the output. The first one, "multiple positive outcomes within groups encountered", we expected. Our data do indeed have multiple positive outcomes (`union` = 1) in many groups. (Here a group consists of all the observations for a particular individual.)

The second message tells us that 2,744 groups were "dropped" by `clogit`. When either `union` = 0 or `union` = 1 for all observations for an individual, this individual's contribution to the log-likelihood is zero. Although these are perfectly valid observations in every sense, they have no effect on the estimation, so they are not included in the total "Number of obs". Hence, the reported "Number of obs" gives the effective sample size of the estimation. Here it is 12,035 observations—only 46% of the total 26,200.

We can easily check that there are indeed 2,744 groups with `union` either all 0 or all 1. We will generate a variable that contains the fraction of observations for each individual who has `union` = 1.

```
. by idcode, sort: generate fraction = sum(union)/sum(union < .)
. by idcode: replace fraction = . if _n < _N
(21766 real changes made, 21766 to missing)
. tabulate fraction
```

fraction	Freq.	Percent	Cum.
0	2,481	55.95	55.95
.0833333	30	0.68	56.63
.0909091	33	0.74	57.37
.1	53	1.20	58.57
(*output omitted*)			
.9	10	0.23	93.59
.9090909	11	0.25	93.84
.9166667	10	0.23	94.07
1	263	5.93	100.00
Total	4,434	100.00	

Because $2481 + 263 = 2744$, we confirm what `clogit` did.

The third warning message from `clogit` said "black omitted because of no within-group variance". Obviously, race stays constant for an individual across time. Any such variables are collinear with the α_i (that is, the fixed effects), and just as the α_i drop out of the conditional likelihood, so do all variables that are unchanging within groups. Thus they cannot be estimated with the conditional fixed-effects model.

There are several other estimators implemented in Stata that we could use with these data:

```
cloglog ... ,  vce(cluster idcode)
logit ... ,  vce(cluster idcode)
probit ... ,  vce(cluster idcode)
scobit ... ,  vce(cluster idcode)
xtcloglog ...
xtgee ... , family(binomial) link(logit) corr(exchangeable)
xtlogit ...
xtprobit ...
```

See [R] **cloglog**, [R] **logit**, [R] **probit**, [R] **scobit**, [XT] **xtcloglog**, [XT] **xtgee**, [XT] **xtlogit**, and [XT] **xtprobit** for details.

Functions

e(sample)	marks estimation sample

Methods and formulas

clogit is implemented as an ado-file.

Breslow and Day (1980, 247–279), Collett (2003, 251–267), and Hosmer and Lemeshow (2000, 223–259) provide a biostatistical point of view on conditional logistic regression. Hamerle and Ronning (1995) give a succinct and lucid review of fixed-effects logit; Chamberlain (1980) is a standard reference for this model. Greene (2012, chap. 17) provides a straightforward textbook description of conditional logistic regression from an economist's point of view, as well as a brief description of choice models.

Let $i = 1, 2, \ldots, n$ denote the groups and let $t = 1, 2, \ldots, T_i$ denote the observations for the ith group. Let y_{it} be the dependent variable taking on values 0 or 1. Let $\mathbf{y}_i = (y_{i1}, \ldots, y_{iT_i})$ be the outcomes for the ith group as a whole. Let $\mathbf{x}_{it}$ be a row vector of covariates. Let

$$k_{1i} = \sum_{t=1}^{T_i} y_{it}$$

be the observed number of ones for the dependent variable in the ith group. Biostatisticians would say that there are k_{1i} cases matched to $k_{2i} = T_i - k_{1i}$ controls in the ith group.

We consider the probability of a possible value of $\mathbf{y}_i$ conditional on $\sum_{t=1}^{T_i} y_{it} = k_{1i}$ (Hamerle and Ronning 1995, eq. 8.33; Hosmer and Lemeshow 2000, eq. 7.4),

$$\Pr\left(\mathbf{y}_i \mid \textstyle\sum_{t=1}^{T_i} y_{it} = k_{1i}\right) = \frac{\exp\left(\sum_{t=1}^{T_i} y_{it}\mathbf{x}_{it}\boldsymbol{\beta}\right)}{\sum_{\mathbf{d}_i \in S_i} \exp\left(\sum_{t=1}^{T_i} d_{it}\mathbf{x}_{it}\boldsymbol{\beta}\right)}$$

where d_{it} is equal to 0 or 1 with $\sum_{t=1}^{T_i} d_{it} = k_{1i}$, and S_i is the set of all possible combinations of k_{1i} ones and k_{2i} zeros. Clearly, there are $\binom{T_i}{k_{1i}}$ such combinations, but we need not count all these combinations to compute the denominator of the above equation. It can be computed recursively.

Denote the denominator by

$$f_i(T_i, k_{1i}) = \sum_{\mathbf{d}_i \in S_i} \exp\left(\sum_{t=1}^{T_i} d_{it}\mathbf{x}_{it}\boldsymbol{\beta}\right)$$

Consider, computationally, how f_i changes as we go from a total of 1 observation in the group to 2 observations to 3, etc. Doing this, we derive the recursive formula

$$f_i(T, k) = f_i(T-1, k) + f_i(T-1, k-1)\, \exp(\mathbf{x}_{iT}\boldsymbol{\beta})$$

where we define $f_i(T, k) = 0$ if $T < k$ and $f_i(T, 0) = 1$.

The conditional log-likelihood is

$$\ln L = \sum_{i=1}^{n} \left\{ \sum_{t=1}^{T_i} y_{it}\mathbf{x}_{it}\boldsymbol{\beta} - \log f_i(T_i, k_{1i}) \right\}$$

The derivatives of the conditional log-likelihood can also be computed recursively by taking derivatives of the recursive formula for f_i.

Computation time is roughly proportional to

$$p^2 \sum_{i=1}^{n} T_i \, \min(k_{1i}, k_{2i})$$

where p is the number of independent variables in the model. If $\min(k_{1i}, k_{2i})$ is small, computation time is not an issue. But if it is large—say, 100 or more—patience may be required.

If T_i is large for all groups, the bias of the unconditional fixed-effects estimator is not a concern, and we can confidently use `logit` with an indicator variable for each group (provided, of course, that the number of groups does not exceed `matsize`; see [R] **matsize**).

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using `vce(robust)` and `vce(cluster` *clustvar*`)`. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. Specifying `vce(robust)` is equivalent to specifying `vce(cluster` *groupvar*`)`, where *groupvar* is the variable for the matched groups.

`clogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

clogit postestimation — Postestimation tools for clogit

Description

The following standard postestimation commands are available after `clogit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`[2]	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

[2] The default prediction statistic `pc1` cannot be correctly handled by `margins`; however, `margins` can be used after `clogit` with options `predict(pu0)` and `predict(xb)`.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

statistic	Description
Main	
pc1	probability of a positive outcome; the default
pu0	probability of a positive outcome, assuming fixed effect is zero
xb	linear prediction
stdp	standard error of the linear prediction
* dbeta	Delta-β influence statistic
* dx2	Delta-χ^2 lack-of-fit statistic
* gdbeta	Delta-β influence statistic for each group
* gdx2	Delta-χ^2 lack-of-fit statistic for each group
* hat	Hosmer and Lemeshow leverage
* residuals	Pearson residuals
* rstandard	standardized Pearson residuals
score	first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

Starred statistics are available for multiple controls per case-matching design only. They are not available if `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweights` were specified with `clogit`.

`dbeta`, `dx2`, `gdbeta`, `gdx2`, `hat`, and `rstandard` are not available if `constraints()` was specified with `clogit`.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pc1`, the default, calculates the probability of a positive outcome conditional on one positive outcome within group.

`pu0` calculates the probability of a positive outcome, assuming that the fixed effect is zero.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Delta-β influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation.

`dx2` calculates the Delta-χ^2 influence statistic, reflecting the decrease in the Pearson chi-squared that is due to deletion of the observation.

`gdbeta` calculates the approximation to the Pregibon stratum-specific Delta-β influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the entire stratum.

`gdx2` calculates the approximation to the Pregibon stratum-specific Delta-χ^2 influence statistic, reflecting the decrease in the Pearson chi-squared that is due to deletion of the entire stratum.

`hat` calculates the Hosmer and Lemeshow leverage or the diagonal element of the hat matrix.

`residuals` calculates the Pearson residuals.

`rstandard` calculates the standardized Pearson residuals.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_{it}\boldsymbol{\beta})$.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `clogit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$. This option cannot be specified with `dbeta`, `dx2`, `gdbeta`, `gdx2`, `hat`, and `rstandard`.

Remarks

`predict` may be used after `clogit` to obtain predicted values of the index $\mathbf{x}_{it}\boldsymbol{\beta}$. Predicted probabilities for conditional logistic regression must be interpreted carefully. Probabilities are estimated for each group as a whole, not for individual observations. Furthermore, the probabilities are conditional on the number of positive outcomes in the group (that is, the number of cases and the number of controls), or it is assumed that the fixed effect is zero. `predict` may also be used to obtain influence and lack of fit statistics for an individual observation and for the whole group, to compute Pearson, standardized Pearson residuals, and leverage values.

`predict` may be used for both within-sample and out-of-sample predictions.

▷ Example 1

Suppose that we have $1:k_{2i}$ matched data and that we have previously fit the following model:

```
. use http://www.stata-press.com/data/r12/clogitid
. clogit y x1 x2, group(id)
  (output omitted)
```

To obtain the predicted values of the index, we could type `predict idx, xb` to create a new variable called `idx`. From `idx`, we could then calculate the predicted probabilities. Easier, however, would be to type

```
. predict phat
(option pc1 assumed; probability of success given one success within group)
```

`phat` would then contain the predicted probabilities.

As noted previously, the predicted probabilities are really predicted probabilities for the group as a whole (that is, they are the predicted probability of observing $y_{it} = 1$ *and* $y_{it'} = 0$ for all $t' \neq t$). Thus, if we want to obtain the predicted probabilities for the estimation sample, it is important that, when we make the calculation, predictions be restricted to the same sample on which we estimated the data. We cannot predict the probabilities and then just keep the relevant ones because the entire sample determines each probability. Thus, assuming that we are not attempting to make out-of-sample predictions, we type

```
. predict phat2 if e(sample)
(option pc1 assumed; probability of success given one success within group)
```

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Recall that $i = 1, \ldots, n$ denote the groups and $t = 1, \ldots, T_i$ denote the observations for the ith group.

`predict` produces probabilities of a positive outcome within group conditional on there being one positive outcome (`pc1`),

$$\Pr\left(y_{it} = 1 \;\middle|\; \sum_{t=1}^{T_i} y_{it} = 1\right) = \frac{\exp(\mathbf{x}_{it}\boldsymbol{\beta})}{\sum_{t=1}^{T_i} \exp(\mathbf{x}_{it}\boldsymbol{\beta})}$$

or `predict` calculates the unconditional `pu0`:

$$\Pr(y_{it} = 1) = \frac{\exp(\mathbf{x}_{it}\boldsymbol{\beta})}{1 + \exp(\mathbf{x}_{it}\boldsymbol{\beta})}$$

Let $N = \sum_{j=1}^{n} T_j$ denote the total number of observations, p denote the number of covariates, and $\widehat{\theta}_{it}$ denote the conditional predicted probabilities of a positive outcome (`pc1`).

For the multiple control per case ($1 : k_{2i}$) matching, Hosmer and Lemeshow (2000, 248–251) propose the following diagnostics:

The Pearson residual is

$$r_{it} = \frac{(y_{it} - \widehat{\theta}_{it})}{\sqrt{\widehat{\theta}_{it}}}$$

The leverage (hat) value is defined as

$$h_{it} = \widehat{\theta}_{it}\widetilde{\mathbf{x}}_{it}^{T}(\widetilde{\mathbf{X}}^{T}\mathbf{U}\widetilde{\mathbf{X}})^{-1}\widetilde{\mathbf{x}}_{it}$$

where $\widetilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \sum_{j=1}^{T_i} \mathbf{x}_{ij}\widehat{\theta}_{ij}$ is the $1 \times p$ row vector of centered by a weighted stratum-specific mean covariate values, $\mathbf{U}_N = \text{diag}\{\widehat{\theta}_{it}\}$, and the rows of $\widetilde{\mathbf{X}}_{N\times p}$ are composed of $\widetilde{\mathbf{x}}_{it}$ values.

The standardized Pearson residual is

$$r_{sit} = \frac{r_{it}}{\sqrt{1 - h_{it}}}$$

The lack of fit and influence diagnostics for an individual observation are (respectively) computed as

$$\Delta\chi_{it}^{2} = r_{sit}^{2}$$

and

$$\Delta\widehat{\beta}_{it} = \Delta\chi_{it}^{2}\frac{h_{it}}{1 - h_{it}}$$

The lack of fit and influence diagnostics for the groups are the group-specific totals of the respective individual diagnostics shown above.

Title

cloglog — Complementary log-log regression

Syntax

```
cloglog depvar [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
offset(*varname*)	include *varname* in model with coefficient constrained to 1
asis	retain perfect predictor variables
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, opg, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
eform	report exponentiated coefficients
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, jackknife, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] **11.1.10 Prefix commands**.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] **mi estimate**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce() and weights are not allowed with the svy prefix; see [SVY] **svy**.

fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

coeflegend does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Binary outcomes > Complementary log-log regression

Description

`cloglog` fits maximum-likelihood complementary log-log models.

See [R] **logistic** for a list of related estimation commands.

Options

Model

`noconstant`, `offset(`*varname*`)`; see [R] **estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`eform` displays the exponentiated coefficients and corresponding standard errors and confidence intervals.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `cloglog` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction to complementary log-log regression
Robust standard errors

Introduction to complementary log-log regression

`cloglog` fits maximum likelihood models with dichotomous dependent variables coded as 0/1 (or, more precisely, coded as 0 and not 0).

▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a model explaining whether a car is foreign based on its weight and mileage. Here is an overview of our data:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. keep make mpg weight foreign
. describe
Contains data from http://www.stata-press.com/data/r12/auto.dta
  obs:            74                          1978 Automobile Data
 vars:             4                          13 Apr 2011 17:45
 size:         1,702                          (_dta has notes)
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
make            str18  %-18s                  Make and Model
mpg             int    %8.0g                  Mileage (mpg)
weight          int    %8.0gc                 Weight (lbs.)
foreign         byte   %8.0g       origin     Car type
-------------------------------------------------------------------------------
Sorted by:  foreign
     Note:  dataset has changed since last saved

. inspect foreign
foreign:  Car type                              Number of Observations
-----------------------                    ------------------------------
                                                Total   Integers   Nonintegers
|   #                          Negative           -          -          -
|   #                          Zero              52         52          -
|   #                          Positive          22         22          -
|   #                                         ------     ------     ------
|   #   #                      Total             74         74          -
|   #   #                      Missing            -
+-----------------------     ------
0                       1                       74
   (2 unique values)
      foreign is labeled and all values are documented in the label.
```

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\texttt{foreign} = 1) = F(\beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{mpg})$$

where $F(z) = 1 - \exp\{-\exp(z)\}$.

To fit this model, we type

```
. cloglog foreign weight mpg
Iteration 0:   log likelihood = -34.054593
Iteration 1:   log likelihood = -27.869915
Iteration 2:   log likelihood = -27.742997
Iteration 3:   log likelihood = -27.742769
Iteration 4:   log likelihood = -27.742769
Complementary log-log regression                Number of obs     =         74
                                                Zero outcomes     =         52
                                                Nonzero outcomes  =         22
                                                LR chi2(2)        =      34.58
Log likelihood = -27.742769                     Prob > chi2       =     0.0000
------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0029153   .0006974    -4.18   0.000    -.0042823   -.0015483
         mpg |  -.1422911    .076387    -1.86   0.062    -.2920069    .0074247
       _cons |   10.09694   3.351841     3.01   0.003     3.527448    16.66642
------------------------------------------------------------------------------
```

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least when holding the weight of the car constant.

See [R] **maximize** for an explanation of the output.

◁

❑ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus, if your dependent variable takes on the values 0 and 1, 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `cloglog` y x, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = 1 - \exp\Big\{-\exp(\mathbf{x}_j\boldsymbol{\beta})\Big\}$$

❑

Robust standard errors

If you specify the `vce(robust)` option, `cloglog` reports robust standard errors, as described in [U] **20.20 Obtaining robust variance estimates**. For the model of `foreign` on `weight` and `mpg`, the robust calculation increases the standard error of the coefficient on `mpg` by 44%:

```
. cloglog foreign weight mpg, vce(robust)

Iteration 0:   log pseudolikelihood = -34.054593
Iteration 1:   log pseudolikelihood = -27.869915
Iteration 2:   log pseudolikelihood = -27.742997
Iteration 3:   log pseudolikelihood = -27.742769
Iteration 4:   log pseudolikelihood = -27.742769

Complementary log-log regression                Number of obs     =         74
                                                Zero outcomes     =         52
                                                Nonzero outcomes  =         22

                                                Wald chi2(2)      =      29.74
Log pseudolikelihood = -27.742769               Prob > chi2       =     0.0000

------------------------------------------------------------------------------
             |               Robust
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0029153   .0007484    -3.90   0.000    -.0043822   -.0014484
         mpg |  -.1422911   .1102466    -1.29   0.197    -.3583704    .0737882
       _cons |   10.09694   4.317305     2.34   0.019     1.635174    18.5587
------------------------------------------------------------------------------
```

Without `vce(robust)`, the standard error for the coefficient on `mpg` was reported to be 0.076, with a resulting confidence interval of $[-0.29, 0.01]$.

The `vce(cluster` *clustvar*`)` option can relax the independence assumption required by the complementary log-log estimator to being just independence between clusters. To demonstrate this ability, we will switch to a different dataset.

We are studying unionization of women in the United States by using the `union` dataset; see [XT] **xt**. We fit the following model, ignoring that women are observed an average of 5.9 times each in this dataset:

```
. use http://www.stata-press.com/data/r12/union, clear
(NLS Women 14-24 in 1968)

. cloglog union age grade not_smsa south##c.year

Iteration 0:   log likelihood = -13606.373
Iteration 1:   log likelihood = -13540.726
Iteration 2:   log likelihood = -13540.607
Iteration 3:   log likelihood = -13540.607

Complementary log-log regression                Number of obs     =      26200
                                                Zero outcomes     =      20389
                                                Nonzero outcomes  =       5811

                                                LR chi2(6)        =     647.24
Log likelihood = -13540.607                     Prob > chi2       =     0.0000

```

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, and so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a different time trend for the south. The `vce(cluster` *clustvar*`)` option provides a way to fit this model and obtains correct standard errors:

```
. cloglog union age grade not_smsa south##c.year, vce(cluster id) nolog
Complementary log-log regression                Number of obs     =      26200
                                                Zero outcomes     =      20389
                                                Nonzero outcomes  =       5811
                                                Wald chi2(6)      =     160.76
Log pseudolikelihood = -13540.607               Prob > chi2       =     0.0000
                              (Std. Err. adjusted for 4434 clusters in idcode)

```

These standard errors are larger than those reported by the inappropriate conventional calculation. By comparison, another way we could fit this model is with an equal-correlation population-averaged complementary log-log model:

```
. xtcloglog union age grade not_smsa south##c.year, pa nolog
GEE population-averaged model                   Number of obs      =      26200
Group variable:                       idcode    Number of groups   =       4434
Link:                                 cloglog   Obs per group: min =          1
Family:                              binomial                 avg =        5.9
Correlation:                    exchangeable                 max =         12
                                                Wald chi2(6)       =     234.66
Scale parameter:                             1  Prob > chi2        =     0.0000

```

The coefficient estimates are similar, but these standard errors are smaller than those produced by `cloglog, vce(cluster` *clustvar*`)`. This finding is as we would expect. If the within-panel correlation assumptions are valid, the population-averaged estimator should be more efficient.

In addition to this estimator, we may use the `xtgee` command to fit a panel estimator (with complementary log-log link) and any number of assumptions on the within-idcode correlation.

`cloglog, vce(cluster` *clustvar*`)` is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard-error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation (as do the `xtgee` population-averaged models).

Saved results

`cloglog` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(k)`	number of parameters
`e(k_eq)`	number of equations in `e(b)`
`e(k_eq_model)`	number of equations in overall model test
`e(k_dv)`	number of dependent variables
`e(N_f)`	number of zero outcomes
`e(N_s)`	number of nonzero outcomes
`e(df_m)`	model degrees of freedom
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(chi2)`	χ^2
`e(p)`	significance
`e(rank)`	rank of `e(V)`
`e(ic)`	number of iterations
`e(rc)`	return code
`e(converged)`	`1` if converged, `0` otherwise

Macros

`e(cmd)`	`cloglog`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(clustvar)`	name of cluster variable
`e(offset)`	linear offset variable
`e(chi2type)`	`Wald` or `LR`; type of model χ^2 test
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(opt)`	type of optimization
`e(which)`	`max` or `min`; whether optimizer is to perform maximization or minimization
`e(ml_method)`	type of `ml` method
`e(user)`	name of likelihood-evaluator program
`e(technique)`	maximization technique
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

`e(b)`	coefficient vector
`e(Cns)`	constraints matrix
`e(ilog)`	iteration log (up to 20 iterations)
`e(gradient)`	gradient vector
`e(V)`	variance–covariance matrix of the estimators
`e(V_modelbased)`	model-based variance

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`cloglog` is implemented as an ado-file.

Complementary log-log analysis (related to the gompit model, so named because of its relationship to the Gompertz distribution) is an alternative to logit and probit analysis, but it is unlike these other estimators in that the transformation is not symmetric. Typically, this model is used when the positive (or negative) outcome is rare.

The log-likelihood function for complementary log-log is

$$\ln L = \sum_{j \in S} w_j \ln F(\mathbf{x}_j\mathbf{b}) + \sum_{j \notin S} w_j \ln\Big\{1 - F(\mathbf{x}_j\mathbf{b})\Big\}$$

where S is the set of all observations j such that $y_j \neq 0$, $F(z) = 1 - \exp\big\{-\exp(z)\big\}$, and w_j denotes the optional weights. $\ln L$ is maximized as described in [R] **maximize**.

We can fit a gompit model by reversing the success–failure sense of the dependent variable and using `cloglog`.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. The scores are calculated as $\mathbf{u}_j = [\exp(\mathbf{x}_j\mathbf{b})\exp\big\{-\exp(\mathbf{x}_j\mathbf{b})\big\}/F(\mathbf{x}_j\mathbf{b})]\mathbf{x}_j$ for the positive outcomes and $\{-\exp(\mathbf{x}_j\mathbf{b})\}\mathbf{x}_j$ for the negative outcomes.

`cloglog` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Acknowledgment

We thank Joseph Hilbe of Arizona State University for providing the inspiration for the `cloglog` command (Hilbe 1996, 1998).

Title

cloglog postestimation — Postestimation tools for cloglog

Description

The following postestimation commands are available after `cloglog`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` *statistic* `nooffset`]

statistic	Description
Main	
`pr`	probability of a positive outcome; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction
`score`	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `cloglog`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

Remarks

Once you have fit a model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] **20 Estimation and postestimation commands** and [R] **predict**. Here we will make only a few comments.

`predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, it calculates the linear combination $\mathbf{x}_j\mathbf{b}$, where $\mathbf{x}_j$ are the independent variables in the jth observation and $\mathbf{b}$ is the estimated parameter vector.

With the `stdp` option, `predict` calculates the standard error of the linear prediction, which is not adjusted for replicated covariate patterns in the data.

▷ Example 1

In example 1 in [R] **cloglog**, we fit the complementary log-log model `cloglog foreign weight mpg`. To obtain predicted probabilities,

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. cloglog foreign weight mpg
  (output omitted)
. predict p
(option pr assumed; Pr(foreign))
. summarize foreign p
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
     foreign |        74    .2972973    .4601885          0          1
           p |        74    .2928348      .29732   .0032726   .9446067
```

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

cnsreg — Constrained linear regression

Syntax

`cnsreg` *depvar indepvars* [*if*] [*in*] [*weight*] , `constraints(`*constraints*`)` [*options*]

options	Description
Model	
* `constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
`noconstant`	suppress constant term
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `ols`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
`mse1`	force MSE to be 1
`coeflegend`	display legend instead of statistics

*`constraints(`*constraints*`)` is required.
indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`bootstrap`, `by`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.
`vce()`, `mse1`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.
`aweights`, `fweights`, `pweights`, and `iweights` are allowed; see [U] **11.1.6 weight**.
`mse1` and `coeflegend` do not appear in the dialog.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Constrained linear regression

Description

`cnsreg` fits constrained linear regression models.

Options

Model

`constraints(`*constraints*`)`, `collinear`, `noconstant`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(ols)`, the default, uses the standard variance estimator for ordinary least-squares regression.

Reporting

`level(#)`; see [R] **estimation options**.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following options are available with `cnsreg` but are not shown in the dialog box:

`mse1` is used only in programs and ado-files that use `cnsreg` to fit models other than constrained linear regression. `mse1` sets the mean squared error to 1, thus forcing the variance–covariance matrix of the estimators to be $(\mathbf{X}'\mathbf{D}\mathbf{X})^{-1}$ (see *Methods and formulas* in [R] **regress**) and affecting calculated standard errors. Degrees of freedom for t statistics are calculated as n rather than $n-p+c$, where p is the total number of parameters (prior to restrictions and including the constant) and c is the number of constraints.

`mse1` is not allowed with the `svy` prefix.

`coeflegend`; see [R] **estimation options**.

Remarks

For a discussion of constrained linear regression, see Greene (2012, 121–122); Hill, Griffiths, and Lim (2011, 231–233); or Davidson and MacKinnon (1993, 17).

▷ Example 1

In principle, we can obtain constrained linear regression estimates by modifying the list of independent variables. For instance, if we wanted to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\,\texttt{price} + \beta_2\,\texttt{weight} + u$$

and constrain $\beta_1 = \beta_2$, we could write

$$\texttt{mpg} = \beta_0 + \beta_1(\texttt{price} + \texttt{weight}) + u$$

and run a regression of `mpg` on `price` + `weight`. The estimated coefficient on the sum would be the constrained estimate of β_1 and β_2. Using `cnsreg`, however, is easier:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. constraint 1 price = weight
. cnsreg mpg price weight, constraint(1)
Constrained linear regression                   Number of obs =      74
                                                F(  1,    72) =   37.59
                                                Prob > F      =  0.0000
                                                Root MSE      =   4.722
 ( 1)  price - weight = 0
------------------------------------------------------------------------------
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       price |  -.0009875   .0001611    -6.13   0.000    -.0013086   -.0006664
      weight |  -.0009875   .0001611    -6.13   0.000    -.0013086   -.0006664
       _cons |   30.36718   1.577958    19.24   0.000     27.22158    33.51278
------------------------------------------------------------------------------
```

We define constraints by using the `constraint` command; see [R] **constraint**. We fit the model with `cnsreg` and specify the constraint number or numbers in the `constraints()` option.

Just to show that the results above are correct, here is the result of applying the constraint by hand:

```
. generate x = price + weight
. regress mpg x
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =   37.59
       Model |  838.065767     1  838.065767            Prob > F      =  0.0000
    Residual |  1605.39369    72  22.2971346            R-squared     =  0.3430
-------------+------------------------------           Adj R-squared =  0.3339

------------------------------------------------------------------------------
```

◁

▷ Example 2

Models can be fit subject to multiple simultaneous constraints. We simply define the constraints and then include the constraint numbers in the `constraints()` option. For instance, say that we wish to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\,\texttt{price} + \beta_2\,\texttt{weight} + \beta_3\,\texttt{displ} + \beta_4\,\texttt{gear\_ratio} + \beta_5\,\texttt{foreign} + \beta_6\,\texttt{length} + u$$

subject to the constraints

$$\beta_1 = \beta_2 = \beta_3 = \beta_6$$
$$\beta_4 = -\beta_5 = \beta_0/20$$

(This model, like the one in example 1, is admittedly senseless.) We fit the model by typing

```
. constraint 1 price=weight
. constraint 2 displ=weight
. constraint 3 length=weight
```

```
. constraint 5 gear_ratio = -foreign
. constraint 6 gear_ratio = _cons/20
. cnsreg mpg price weight displ gear_ratio foreign length, c(1-3,5-6)
Constrained linear regression                   Number of obs =      74
                                                F(  2,    72) =  785.20
                                                Prob > F      =  0.0000
                                                Root MSE      =  4.6823

 ( 1)  price - weight = 0
 ( 2) - weight + displacement = 0
 ( 3) - weight + length = 0
 ( 4)  gear_ratio + foreign = 0
 ( 5)  gear_ratio - .05 _cons = 0
```

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
price	-.000923	.0001534	-6.02	0.000	-.0012288	-.0006172
weight	-.000923	.0001534	-6.02	0.000	-.0012288	-.0006172
displacement	-.000923	.0001534	-6.02	0.000	-.0012288	-.0006172
gear_ratio	1.326114	.0687589	19.29	0.000	1.189046	1.463183
foreign	-1.326114	.0687589	-19.29	0.000	-1.463183	-1.189046
length	-.000923	.0001534	-6.02	0.000	-.0012288	-.0006172
_cons	26.52229	1.375178	19.29	0.000	23.78092	29.26365

There are many ways we could have specified the `constraints()` option (which we abbreviated `c()` above). We typed `c(1-3,5-6)`, meaning that we want constraints 1 through 3 and 5 and 6; those numbers correspond to the constraints we defined. The only reason we did not use the number 4 was to emphasize that constraints do not have to be consecutively numbered. We typed `c(1-3,5-6)`, but we could have typed `c(1,2,3,5,6)` or `c(1-3,5,6)` or `c(1-2,3,5,6)` or even `c(1-6)`, which would have worked as long as constraint 4 was not defined. If we had previously defined a constraint 4, then `c(1-6)` would have included it.

◁

Saved results

cnsreg saves the following in e():

Scalars

e(N)	number of observations
e(df_m)	model degrees of freedom
e(df_r)	residual degrees of freedom
e(F)	F statistic
e(rmse)	root mean squared error
e(ll)	log likelihood
e(N_clust)	number of clusters
e(rank)	rank of e(V)

Macros

e(cmd)	cnsreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

cnsreg is implemented as an ado-file.

Let n be the number of observations, p be the total number of parameters (prior to restrictions and including the constant), and c be the number of constraints. The coefficients are calculated as $\mathbf{b}' = \mathbf{T}\{(\mathbf{T}'\mathbf{X}'\mathbf{W}\mathbf{X}\mathbf{T})^{-1}(\mathbf{T}'\mathbf{X}'\mathbf{W}\mathbf{y} - \mathbf{T}'\mathbf{X}'\mathbf{W}\mathbf{X}\mathbf{a}')\} + \mathbf{a}'$, where $\mathbf{T}$ and $\mathbf{a}$ are as defined in [P] **makecns**. $\mathbf{W} = \mathbf{I}$ if no weights are specified. If weights are specified, let $\mathbf{v}$: $1 \times n$ be the specified weights. If fweight frequency weights are specified, $\mathbf{W} = \mathrm{diag}(\mathbf{v})$. If aweight analytic weights are specified, then $\mathbf{W} = \mathrm{diag}[\mathbf{v}/(\mathbf{1}'\mathbf{v})(\mathbf{1}'\mathbf{1})]$, meaning that the weights are normalized to sum to the number of observations.

The mean squared error is $s^2 = (\mathbf{y}'\mathbf{W}\mathbf{y} - 2\mathbf{b}'\mathbf{X}'\mathbf{W}\mathbf{y} + \mathbf{b}'\mathbf{X}'\mathbf{W}\mathbf{X}\mathbf{b})/(n-p+c)$. The variance–covariance matrix is $s^2\mathbf{T}(\mathbf{T}'\mathbf{X}'\mathbf{W}\mathbf{X}\mathbf{T})^{-1}\mathbf{T}'$.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster *clustvar*), respectively. See [P] **_robust**, particularly *Introduction* and *Methods and formulas*.

cnsreg also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

cnsreg postestimation — Postestimation tools for cnsreg

Description

The following postestimation commands are available after `cnsreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat (svy)`.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [, *statistic*]

statistic	Description
Main	
`xb`	linear prediction; the default
`residuals`	residuals
`stdp`	standard error of the prediction
`stdf`	standard error of the forecast
`pr(`*a*`,`*b*`)`	$\Pr(a < y_j < b)$
`e(`*a*`,`*b*`)`	$E(y_j \mid a < y_j < b)$
`ystar(`*a*`,`*b*`)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$
`score`	equivalent to `residuals`

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where a and b may be numbers or variables; a missing ($a \geq .$) means $-\infty$, and b missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, that is, $y_j - \mathbf{x}_j\mathbf{b}$.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \,|\, a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated. *a* and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`score` is equivalent to `residuals` for linear regression models.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

constraint — Define and list constraints

Syntax

Define constraints

```
constraint [define] # [exp=exp | coeflist]
```

List constraints

```
constraint dir [numlist | _all]

constraint list [numlist | _all]
```

Drop constraints

```
constraint drop {numlist | _all}
```

Programmer's commands

```
constraint get #

constraint free
```

where *coeflist* is as defined in [R] **test** and # is restricted to the range 1–1,999, inclusive.

Menu

Statistics > Other > Manage constraints

Description

`constraint` defines, lists, and drops linear constraints. Constraints are for use by models that allow constrained estimation.

Constraints are defined by the `constraint` command. The currently defined constraints can be listed by either `constraint list` or `constraint dir`; both do the same thing. Existing constraints can be eliminated by `constraint drop`.

`constraint get` and `constraint free` are programmer's commands. `constraint get` returns the contents of the specified constraint in macro `r(contents)` and returns in scalar `r(defined)` 0 or 1—1 being returned if the constraint was defined. `constraint free` returns the number of a free (unused) constraint in macro `r(free)`.

Remarks

Using constraints is discussed in [R] **cnsreg**, [R] **mlogit**, and [R] **reg3**; this entry is concerned only with practical aspects of defining and manipulating constraints.

▷ Example 1

Constraints are numbered from 1 to 1,999, and we assign the number when we define the constraint:

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. constraint 2 [Indemnity]2.site = 0
```

The currently defined constraints can be listed by `constraint list`:

```
. constraint list
     2:  [indemnity]2.site = 0
```

`constraint drop` drops constraints:

```
. constraint drop 2
. constraint list
```

The empty list after `constraint list` indicates that no constraints are defined. Below we demonstrate the various syntaxes allowed by `constraint`:

```
. constraint 1 [Indemnity]
. constraint 10 [Indemnity]: 1.site 2.site
. constraint 11 [Indemnity]: 3.site
. constraint 21 [Prepaid=Uninsure]: nonwhite
. constraint 30 [Prepaid]
. constraint 31 [Insure]
. constraint list
     1:  [Indemnity]
    10:  [Indemnity]: 1.site 2.site
    11:  [Indemnity]: 3.site
    21:  [Prepaid=Uninsure]: nonwhite
    30:  [Prepaid]
    31:  [Insure]
. constraint drop 21-25, 31
. constraint list
     1:  [Indemnity]
    10:  [Indemnity]: 1.site 2.site
    11:  [Indemnity]: 3.site
    30:  [Prepaid]
. constraint drop _all
. constraint list
```

◁

❑ Technical note

The `constraint` command does not check the syntax of the constraint itself because a constraint can be interpreted only in the context of a model. Thus `constraint` is willing to define constraints that later will not make sense. Any errors in the constraints will be detected and mentioned at the time of estimation.

❑

Title

contrast — Contrasts and linear hypothesis tests after estimation

Syntax

```
contrast termlist [ , options ]
```

where *termlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without contrast operators, and you may use any factor-variable syntax:

```
. contrast sex group sex#group
. contrast r.sex
```

See the *operators (op.)* table below for the list of contrast operators.

options	Description
Main	
`overall`	add a joint hypothesis test for all specified contrasts
`asobserved`	treat all factor variables as observed
`lincom`	treat user-defined contrasts as linear combinations
Equations	
`equation(`*eqspec*`)`	perform contrasts in *termlist* for equation *eqspec*
`atequations`	perform contrasts in *termlist* within each equation
Advanced	
`emptycells(`*empspec*`)`	treatment of empty cells for balanced factors
`noestimcheck`	suppress estimability checks
Reporting	
`level(#)`	confidence level; default is `level(95)`
`mcompare(`*method*`)`	adjust for multiple comparisons; default is `mcompare(noadjust)`
`noeffects`	suppress table of individual contrasts
`cieffects`	show effects table with confidence intervals
`pveffects`	show effects table with p-values
`effects`	show effects table with confidence intervals and p-values
`nowald`	suppress table of Wald tests
`noatlevels`	report only the overall Wald test for terms that use the within `@` or nested `|` operator
`nosvyadjust`	compute unadjusted Wald tests for survey results
`sort`	sort the individual contrast values in each term
`post`	post contrasts and their VCEs as estimation results
display_options	control column formats, row spacing, and line width
eform_option	report exponentiated contrasts

Term	Description
Main effects	
`A`	joint test of the main effects of `A`
r`.A`	individual contrasts that decompose `A` using *r*.
Interaction effects	
`A#B`	joint test of the two-way interaction effects of `A` and `B`
`A#B#C`	joint test of the three-way interaction effects of `A`, `B`, and `C`
r`.A#`*g*`.B`	individual contrasts for each interaction of `A` and `B` defined by *r*. and *g*.
Partial interaction effects	
r`.A#B`	joint tests of interactions of `A` and `B` within each contrast defined by *r*`.A`
`A#`*r*`.B`	joint tests of interactions of `A` and `B` within each contrast defined by *r*`.B`
Simple effects	
`A@B`	joint tests of the effects of `A` within each level of `B`
`A@B#C`	joint tests of the effects of `A` within each combination of the levels of `B` and `C`
r`.A@B`	individual contrasts of `A` that decompose `A@B` using *r*.
r`.A@B#C`	individual contrasts of `A` that decompose `A@B#C` using *r*.
Other conditional effects	
`A#B@C`	joint tests of the interaction effects of `A` and `B` within each level of `C`
`A#B@C#D`	joint tests of the interaction effects of `A` and `B` within each combination of the levels of `C` and `D`
r`.A#`*g*`.B@C`	individual contrasts for each interaction of `A` and `B` that decompose `A#B@C` using *r*. and *g*.
Nested effects	
`A|B`	joint tests of the effects of `A` nested in each level of `B`
`A|B#C`	joint tests of the effects of `A` nested in each combination of the levels of `B` and `C`
`A#B|C`	joint tests of the interaction effects of `A` and `B` nested in each level of `C`
`A#B|C#D`	joint tests of the interaction effects of `A` and `B` nested in each combination of the levels of `C` and `D`
r`.A|B`	individual contrasts of `A` that decompose `A|B` using *r*.
r`.A|B#C`	individual contrasts of `A` that decompose `A|B#C` using *r*.
r`.A#`*g*`.B|C`	individual contrasts for each interaction of `A` and `B` defined by *r*. and *g*. nested in each level of `C`
Slope effects	
`A#c.x`	joint test of the effects of `A` on the slopes of `x`
`A#c.x#c.y`	joint test of the effects of `A` on the slopes of the product (interaction) of `x` and `y`
`A#B#c.x`	joint test of the interaction effects of `A` and `B` on the slopes of `x`
`A#B#c.x#c.y`	joint test of the interaction effects of `A` and `B` on the slopes of the product (interaction) of `x` and `y`
r`.A#c.x`	individual contrasts of `A`'s effects on the slopes of `x` using *r*.
Denominators	
`... /` *term2*	use *term2* as the denominator in the F tests of the preceding terms
`... /`	use the residual as the denominator in the F tests of the preceding terms (the default if no other `/`s are specified)

A, B, C, and D represent any factor variable in the current estimation results.

x and y represent any continuous variable in the current estimation results.

r. and *g.* represent any contrast operator. See the table below.

c. specifies that a variable be treated as continuous; see [U] **11.4.3 Factor variables**.

Operators are allowed on any factor variable that does not appear to the right of @ or |. Operators decompose the effects of the associated factor variable into one-degree-of-freedom effects (contrasts).

Higher-level interactions are allowed anywhere an interaction operator (#) appears in the table.

Time-series operators are allowed if they were used in the estimation.

_eqns designates the equations in manova, mlogit, mprobit, and mvreg and can be specified anywhere a factor variable appears.

/ is allowed only after anova, cnsreg, manova, mvreg, or regress.

operators (op.)	Description
r.	differences from a reference (base) level; the default
a.	differences from the next level (adjacent contrasts)
ar.	differences from the previous level (reverse adjacent contrasts)
As-balanced operators	
g.	differences from the balanced grand mean
h.	differences from the balanced mean of subsequent levels (Helmert contrasts)
j.	differences from the balanced mean of previous levels (reverse Helmert contrasts)
p.	orthogonal polynomial in the level values
q.	orthogonal polynomial in the level sequence
As-observed operators	
gw.	differences from the observation-weighted grand mean
hw.	differences from the observation-weighted mean of subsequent levels
jw.	differences from the observation-weighted mean of previous levels
pw.	observation-weighted orthogonal polynomial in the level values
qw.	observation-weighted orthogonal polynomial in the level sequence

One or more individual contrasts may be selected by using the *op#.* or *op*(*numlist*). syntax. For example, a3.A selects the adjacent contrast for level 3 of A, and p(1/2).B selects the linear and quadratic effects of B. Also see *Orthogonal polynomial contrasts* and *Beyond linear models*.

Custom contrasts	Description
{A *numlist*}	user-defined contrast on the levels of factor A
{A#B *numlist*}	user-defined contrast on the levels of the interaction between A and B

Custom contrasts may be part of a term, such as {A *numlist*}#B, {A *numlist*}@B, {A *numlist*}|B, {A#B *numlist*}, and {A *numlist*}#{B *numlist*}. The same is true of higher-order custom contrasts, such as {A#B *numlist*}@C, {A#B *numlist*}#*r.*C, and {A#B *numlist*}#c.x.

Higher-order interactions with at most eight factor variables are allowed with custom contrasts.

method	Description
noadjust	do not adjust for multiple comparisons; the default
bonferroni [adjustall]	Bonferroni's method; adjust across all terms
sidak [adjustall]	Šidák's method; adjust across all terms
scheffe	Scheffé's method

Menu

Statistics > Postestimation > Contrasts

Description

`contrast` tests linear hypotheses and forms contrasts involving factor variables and their interactions from the most recently fit model. The tests include ANOVA-style tests of main effects, simple effects, interactions, and nested effects. `contrast` can use named contrasts to decompose these effects into comparisons against reference categories, comparisons of adjacent levels, comparisons against the grand mean, orthogonal polynomials, and such. Custom contrasts may also be specified.

`contrast` can be used with `svy` estimation results; see [SVY] **svy postestimation**.

Contrasts can also be computed for margins of linear and nonlinear responses; see [R] **margins, contrast**.

Options

Main

`overall` specifies that a joint hypothesis test over all terms be performed.

`asobserved` specifies that factor covariates be evaluated using the cell frequencies observed in the estimation sample. The default is to treat all factor covariates as though there were an equal number of observations in each level.

`lincom` specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

Equations

`equation(`*eqspec*`)` specifies the equation from which contrasts are to be computed. The default is to compute contrasts from the first equation.

`atequations` specifies that the contrasts be computed within each equation.

Advanced

`emptycells(`*empspec*`)` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced.

`emptycells(strict)` is the default; it specifies that contrasts involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the contrast estimable but changes its interpretation.

`noestimcheck` specifies that `contrast` not check for estimability. By default, the requested contrasts are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`mcompare(`*method*`)` specifies the method for computing p-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, α_c, to achieve a prespecified experimentwise error rate, α_e.

`mcompare(noadjust)` is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare(bonferroni)` adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$\alpha_e \leq m\alpha_c$$

where *m* is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where *m* is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the *m* comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the F or χ^2 distribution with degrees of freedom equal to the rank of the term.

`mcompare(`*method* `adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginslist*. This option is compatible only with the `bonferroni` and `sidak` methods.

`noeffects` suppresses the table of individual contrasts with confidence intervals. This table is produced by default when the `mcompare()` option is specified or when a term in *termlist* implies all individual contrasts.

`cieffects` specifies that a table containing a confidence interval for each individual contrast be reported.

`pveffects` specifies that a table containing a p-value for each individual contrast be reported.

`effects` specifies that a single table containing a confidence interval and p-value for each individual contrast be reported.

`nowald` suppresses the table of Wald tests.

`noatlevels` indicates that only the overall Wald test be reported for each term containing within or nested (`@` or `|`) operators.

`nosvyadjust` is for use with `svy` estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as $W/k \sim F(k,d)$ rather than as $(d-k+1)W/(kd) \sim F(k,d-k+1)$, where k is the dimension of the test and d is the total number of sampled PSUs minus the total number of strata.

`sort` specifies that the table of individual contrasts be sorted by the contrast values within each term.

`post` causes `contrast` to behave like a Stata estimation (e-class) command. `contrast` posts the vector of estimated contrasts along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated contrasts just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the contrasts, or you could use `lincom` to create linear combinations.

display_options: `vsquish`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`cformat(%`*fmt*`)` specifies how to format contrasts, standard errors, and confidence limits in the table of estimated contrasts.

`pformat(%`*fmt*`)` specifies how to format p-values in the table of estimated contrasts.

`sformat(%`*fmt*`)` specifies how to format test statistics in the table of estimated contrasts.

`nolstretch` specifies that the width of the table of estimated contrasts not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of estimated contrasts up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

eform_option specifies that the contrasts table be displayed in exponentiated form. e^{contrast} is displayed rather than contrast. Standard errors and confidence intervals are also transformed. See [R] ***eform_option*** for the list of available options.

Remarks

Remarks are presented under the following headings:

Introduction
One-way models
  Estimated cell means
  Testing equality of cell means
  Reference category contrasts

Unbalanced data
  Using observed cell frequencies
  Weighted contrast operators
Testing factor effects on slopes
Chow tests
Beyond linear models
Multiple equations

Introduction

`contrast` performs ANOVA-style tests of main effects, interactions, simple effects, and nested effects. It can easily decompose these tests into constituent contrasts using either named contrasts (codings) or user-specified contrasts. Comparing levels of factor variables—whether as main effects, interactions, or simple effects—is as easy as adding a contrast operator to the variable. The operators can compare each level with the previous level, each level with a reference level, each level with the mean of previous levels, and more.

`contrast` tests and estimates contrasts. A contrast of the parameters $\mu_1, \mu_2, \ldots, \mu_p$ is a linear combination $\sum_i c_i\mu_i$ whose c_i sum to zero. A difference of population means that $\mu_1 - \mu_2$ is a contrast, as are most other comparisons of population or model quantities (Coster 2005). Some contrasts may be estimated with `lincom`, but `contrast` is much more powerful. `contrast` can handle multiple contrasts simultaneously, and the command's contrast operators make it easy to specify complicated linear combinations.

Both the contrast operation and the creation of the margins for comparison can be performed as though the data were balanced (typical for experimental designs) or using the observed frequencies in the estimation sample (typical for observational studies). `contrast` can perform these analyses on the results of almost all of Stata's estimators, not just the linear-models estimators.

Most of contrast's computations can be considered comparisons of estimated cell means from a model fit. Tests of interactions are tests of whether the cell means for the interaction are all equal. Tests of main effects are tests of whether the marginal cell means for the factor are all equal. More focused comparisons of cell means (for example, is level 2 equal to level 1) are specified using contrast operators. More formally, all of contrast's computations are comparisons of conditional expectations; cell means are one type of conditional expectation.

All contrasts can also easily be graphed; see [R] **marginsplot**.

For a discussion of contrasts and testing for linear models, see Searle (1971) and Searle (1997). For discussions specifically related to experimental design, see Kuehl (2000), Winer, Brown, and Michels (1991), and Milliken and Johnson (2009). Rosenthal, Rosnow, and Rubin (2000) focus on contrasts with applications in behavioral sciences.

contrast is a flexible tool for understanding the effects of categorical covariates. If your model contains categorical covariates, and especially if it contains interactions, you will want to use contrast.

One-way models

Suppose we have collected data on cholesterol levels for individuals from five age groups. To study the effect of age group on cholesterol, we can begin by fitting a one-way model using regress:

```
. use http://www.stata-press.com/data/r12/cholesterol
(Artificial cholesterol data)
. label list ages
ages:
           1 10-19
           2 20-29
           3 30-39
           4 40-59
           5 60-79
. regress chol i.agegrp
      Source |       SS       df       MS              Number of obs =      75
-------------+------------------------------           F(  4,    70) =   35.02
       Model |  14943.3997     4  3735.84993            Prob > F      =  0.0000
    Residual |  7468.21971    70  106.688853            R-squared     =  0.6668
-------------+------------------------------           Adj R-squared =  0.6477
       Total |  22411.6194    74  302.859722            Root MSE      =  10.329

------------------------------------------------------------------------------
        chol |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------

          2  |   8.203575   3.771628     2.18   0.033     .6812991    15.72585
          3  |   21.54105   3.771628     5.71   0.000     14.01878    29.06333
          4  |   30.15067   3.771628     7.99   0.000      22.6284    37.67295
          5  |   38.76221   3.771628    10.28   0.000     31.23993    46.28448
             |
       _cons |   180.5198   2.666944    67.69   0.000     175.2007    185.8388
------------------------------------------------------------------------------
```

Estimated cell means

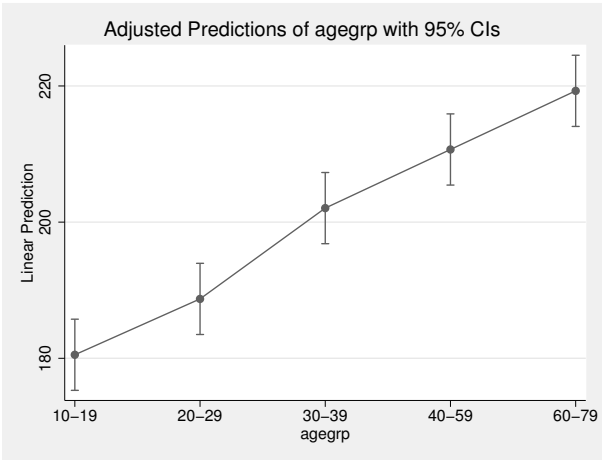
`margins` will show us the estimated cell means for each age group based on our fitted model:

```
. margins agegrp
Adjusted predictions                              Number of obs   =         75
Model VCE    : OLS
Expression   : Linear prediction, predict()
```

	Delta-method					
	Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
agegrp						
1	180.5198	2.666944	67.69	0.000	175.2926	185.7469
2	188.7233	2.666944	70.76	0.000	183.4962	193.9504
3	202.0608	2.666944	75.76	0.000	196.8337	207.2879
4	210.6704	2.666944	78.99	0.000	205.4433	215.8975
5	219.282	2.666944	82.22	0.000	214.0548	224.5091

We can graph those means with `marginsplot`:

```
. marginsplot
  Variables that uniquely identify margins: agegrp
```



Testing equality of cell means

Are all the means equal? That is to say is there an effect of age group on cholesterol level? We can answer that by asking `contrast` to test whether the means of the age groups are identical.

```
. contrast agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp	4	35.02	0.0000
Residual	70		

The means are clearly different. We could have obtained this same test directly had we fit our model using `anova` rather than `regress`.

```
. anova chol agegrp
                    Number of obs =      75     R-squared     =  0.6668
                    Root MSE      =  10.329     Adj R-squared =  0.6477
```

Source	Partial SS	df	MS	F	Prob > F
Model	14943.3997	4	3735.84993	35.02	0.0000
agegrp	14943.3997	4	3735.84993	35.02	0.0000
Residual	7468.21971	70	106.688853		
Total	22411.6194	74	302.859722		

Achieving a more direct test result is why we recommend using `anova` instead of `regress` for models where our focus is on the categorical covariates. The models fit by `anova` and `regress` are identical; they merely parameterize the effects differently. The results of `contrast` will be identical regardless of which command is used to fit the model. If, however, we were fitting models whose responses are nonlinear functions of the covariates, such as logistic regression, then there would be no analogue to `anova`, and we would appreciate `contrast`'s ability to quickly test main effects and interactions.

Reference category contrasts

Now that we know that the overall effect of age group is statistically significant, we can explore the effects of each age group. One way to do that is to use the reference category operator, `r.`:

```
. contrast r.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(2 vs 1)	1	4.73	0.0330
(3 vs 1)	1	32.62	0.0000
(4 vs 1)	1	63.91	0.0000
(5 vs 1)	1	105.62	0.0000
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(2 vs 1)	8.203575	3.771628	.6812991	15.72585
(3 vs 1)	21.54105	3.771628	14.01878	29.06333
(4 vs 1)	30.15067	3.771628	22.6284	37.67295
(5 vs 1)	38.76221	3.771628	31.23993	46.28448

The cell mean of each age group is compared against the base age group (group 1, ages 10–19). The first table shows that each difference is significant. The second table gives an estimate and confidence interval for each contrast. These are the comparisons that linear regression gives with a factor covariate and no interactions. The contrasts are identical to the coefficients from our linear regression.

Reverse adjacent contrasts

We have far more flexibility with `contrast`. Age group is ordinal, so it is interesting to compare each age group with the preceding age group (rather than against one reference group). We specify that analysis by using the reverse adjacent operator, `ar.`:

```
. contrast ar.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(2 vs 1)	1	4.73	0.0330
(3 vs 2)	1	12.51	0.0007
(4 vs 3)	1	5.21	0.0255
(5 vs 4)	1	5.21	0.0255
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(2 vs 1)	8.203575	3.771628	.6812991	15.72585
(3 vs 2)	13.33748	3.771628	5.815204	20.85976
(4 vs 3)	8.60962	3.771628	1.087345	16.1319
(5 vs 4)	8.611533	3.771628	1.089257	16.13381

Age group 2's cholesterol level is 8.2 points higher than age group 1's; age group 3's is 13.3 points higher than age group 2's; and so on. Each age group is statistically different from the preceding age group at the 5% level.

Orthogonal polynomial contrasts

The relationship between age group and cholesterol level looked almost linear in our graph. We can examine that relationship further by using the orthogonal polynomial operator, `p.`:

```
. contrast p.agegrp, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(linear)	1	139.11	0.0000
(quadratic)	1	0.15	0.6962
(cubic)	1	0.37	0.5448
(quartic)	1	0.43	0.5153
Joint	4	35.02	0.0000
Residual	70		

Only the linear effect is statistically significant.

We can even perform the joint test that all effects beyond linear are zero. We do that by selecting all polynomial contrasts above linear—that is, polynomial contrasts 2, 3, and 4.

```
. contrast p(2 3 4).agegrp, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(quadratic)	1	0.15	0.6962
(cubic)	1	0.37	0.5448
(quartic)	1	0.43	0.5153
Joint	3	0.32	0.8129
Residual	70		

The joint test has three degrees of freedom and is clearly insignificant. A linear effect of age group seems adequate for this model.

Two-way models

Suppose we are investigating the effects of different dosages of a blood pressure medication and believe that the effects may be different for men and women. We can fit the following ANOVA model for `bpchange`, the change in diastolic blood pressure. Change is defined as the after measurement minus the before measurement, so that negative values of `bpchange` correspond to decreases in blood pressure.

```
. use http://www.stata-press.com/data/r12/bpchange
(Artificial blood pressure data)
. label list gender
gender:
           1 male
           2 female
. anova bpchange dose##gender
```

Number of obs =	30	R-squared	=	0.9647	
Root MSE =	1.4677	Adj R-squared	=	0.9573	

Source	Partial SS	df	MS	F	Prob > F
Model	1411.9087	5	282.381741	131.09	0.0000
dose	963.481795	2	481.740897	223.64	0.0000
gender	355.118817	1	355.118817	164.85	0.0000
dose#gender	93.3080926	2	46.6540463	21.66	0.0000
Residual	51.699253	24	2.15413554		
Total	1463.60796	29	50.4692399		

Estimated interaction cell means

Everything is significant, including the interaction. So increasing dosage is effective and differs by gender. Let's explore the effects. First, let's look at the estimated cell mean of blood pressure change for each combination of gender and dosage.

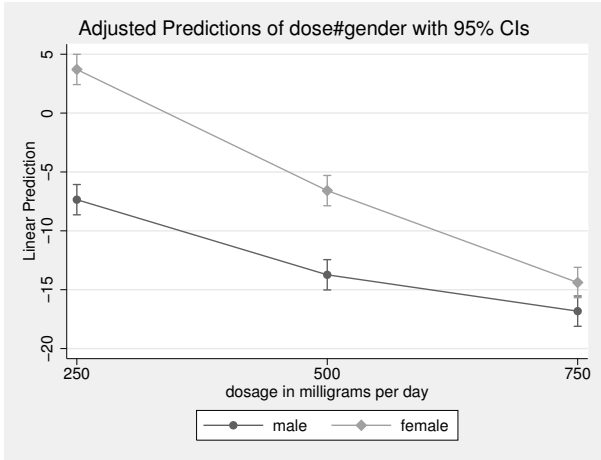
```
. margins dose#gender
Adjusted predictions                              Number of obs   =         30
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
dose#gender						
250 1	-7.35384	.6563742	-11.20	0.000	-8.64031	-6.06737
250 2	3.706567	.6563742	5.65	0.000	2.420097	4.993037
500 1	-13.73386	.6563742	-20.92	0.000	-15.02033	-12.44739
500 2	-6.584167	.6563742	-10.03	0.000	-7.870637	-5.297697
750 1	-16.82108	.6563742	-25.63	0.000	-18.10754	-15.53461
750 2	-14.38795	.6563742	-21.92	0.000	-15.67442	-13.10148

Our data are balanced, so these results will not be affected by the many different ways that `margins` can compute cell means. Moreover, because our model consists of only `dose` and `gender`, these are also the point estimates for each combination.

We can graph the results:

```
. marginsplot
  Variables that uniquely identify margins: dose gender
```



The lines are not parallel, which we expected because the interaction term is significant. Males experience a greater decline in blood pressure at every dosage level, but the effect of increasing dosage is greater for females. In fact, it is not clear if we can tell the difference between male and female response at the maximum dosage.

Simple effects

We can contrast the male and female responses within dosage to see the simple effects of `gender`. Because there are only two levels in `gender`, the choice of contrast operator is largely irrelevant. Aside from orthogonal polynomials, all operators produce the same estimates, although the effects can change signs.

```
. contrast r.gender@dose
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
gender@dose			
(2 vs 1) 250	1	141.97	0.0000
(2 vs 1) 500	1	59.33	0.0000
(2 vs 1) 750	1	6.87	0.0150
Joint	3	69.39	0.0000
Residual	24		

	Contrast	Std. Err.	[95% Conf.	Interval]
gender@dose				
(2 vs 1) 250	11.06041	.9282533	9.144586	12.97623
(2 vs 1) 500	7.149691	.9282533	5.23387	9.065512
(2 vs 1) 750	2.433124	.9282533	.5173031	4.348944

The effect for males is about 11 points higher than for females at a dosage of 250, and that shrinks to 2.4 points higher at the maximum dosage of 750.

We can form the simple effects the other way by contrasting the effect of `dose` at each level of `gender`:

```
. contrast ar.dose@gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose@gender			
(500 vs 250) 1	1	47.24	0.0000
(500 vs 250) 2	1	122.90	0.0000
(750 vs 500) 1	1	11.06	0.0028
(750 vs 500) 2	1	70.68	0.0000
Joint	4	122.65	0.0000
Residual	24		

	Contrast	Std. Err.	[95% Conf.	Interval]
dose@gender				
(500 vs 250) 1	-6.380018	.9282533	-8.295839	-4.464198
(500 vs 250) 2	-10.29073	.9282533	-12.20655	-8.374914
(750 vs 500) 1	-3.087217	.9282533	-5.003038	-1.171396
(750 vs 500) 2	-7.803784	.9282533	-9.719605	-5.887963

Here we use the `ar.` reverse adjacent contrast operator so that first we are comparing a dosage of 500 with a dosage of 250, and then we are comparing 750 with 500. We see that increasing the dosage has a larger effect on females—10.3 points when going from 250 to 500 compared with 6.4 points for males, and 7.8 points when going from 500 to 750 versus 3.1 points for males.

Interaction effects

By specifying contrast operators on both factors, we can decompose the interaction effect into separate interaction contrasts.

```
. contrast ar.dose#r.gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose#gender			
(500 vs 250) (2 vs 1)	1	8.87	0.0065
(750 vs 500) (2 vs 1)	1	12.91	0.0015
Joint	2	21.66	0.0000
Residual	24		

	Contrast	Std. Err.	[95% Conf.	Interval]
dose#gender				
(500 vs 250) (2 vs 1)	-3.910716	1.312748	-6.620095	-1.201336
(750 vs 500) (2 vs 1)	-4.716567	1.312748	-7.425947	-2.007187

Look for departures from zero to indicate an interaction effect between `dose` and `gender`. Both contrasts are significantly different from zero. Of course, we already knew the overall interaction was significant from our ANOVA results. The effect of increasing `dose` from 250 to 500 is 3.9 points greater in females than in males, and the effect of increasing `dose` from 500 to 750 is 4.7 points greater in females than in males. The confidence intervals for both estimates easily exclude zero, meaning that there is an interaction effect.

The joint test of these two interaction effects reproduces the test of interaction effects in the `anova` output. We can see that the F statistic of 21.66 matches the statistic from our original ANOVA results.

Main effects

We can perform tests of the main effects by listing each variable individually in `contrast`.

```
. contrast dose gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose	2	223.64	0.0000
gender	1	164.85	0.0000
Residual	24		

The F tests are equivalent to the tests of main effects in the `anova` output. This is true only for linear models. `contrast` provides an easy way to obtain main effects and other ANOVA-style tests for models whose responses are not linear in the parameters—`logistic`, `probit`, `glm`, etc.

If we include contrast operators on the variables, we can also decompose the main effects into individual contrasts:

```
. contrast ar.dose r.gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose			
(500 vs 250)	1	161.27	0.0000
(750 vs 500)	1	68.83	0.0000
Joint	2	223.64	0.0000
gender	1	164.85	0.0000
Residual	24		

	Contrast	Std. Err.	[95% Conf.	Interval]
dose				
(500 vs 250)	-8.335376	.6563742	-9.690066	-6.980687
(750 vs 500)	-5.4455	.6563742	-6.80019	-4.090811
gender				
(2 vs 1)	6.881074	.5359273	5.774974	7.987173

By specifying the `ar.` operator on `dose`, we decompose the main effect for dose into two one-degree-of-freedom contrasts, comparing the marginal mean of blood pressure change for each dosage level with that of the previous level. Because `gender` has only two levels, we cannot decompose this main effect any further. However, specifying a contrast operator on `gender` allowed us to calculate the difference in the marginal means for women and men.

Partial interaction effects

At this point, we have looked at the total interaction effects and at the main effects of each variable. The partial interaction effects are a midpoint between these two types of effects where we collect the individual interaction effects along the levels of one of the variables and perform a joint test of those interactions. If we think of the interaction effects as forming a table, with the levels of one factor variable forming the rows and the levels of the other forming the columns, partial interaction effects are joint tests of the interactions in a row or a column. To perform these tests, we specify a contrast operator on only one of the variables in our interaction. For this particular model, these are not very interesting because our variables have only two and three levels. Therefore, the tests of the partial interaction effects reproduce the tests that we obtained for the total interaction effects. We specify a contrast operator only on `dose` to decompose the overall test for interaction effects into joint tests for each `ar.dose` contrast:

```
. contrast ar.dose#gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose#gender			
(500 vs 250) (joint)	1	8.87	0.0065
(750 vs 500) (joint)	1	12.91	0.0015
Joint	2	21.66	0.0000
Residual	24		

The first row is a joint test of all the interaction effects involving the `(500 vs 250)` comparison of dosages. The second row is a joint test of all the interaction effects involving the `(750 vs 500)` comparison. If we look back at our output in *Interaction effects*, we can see that there was only one of each of these interaction effects. Therefore, each test labeled `(joint)` has only one degree-of-freedom.

We could have instead included a contrast operator on `gender` to compute the partial interaction effects along the other dimension:

```
. contrast dose#r.gender
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
dose#gender	2	21.66	0.0000
Residual	24		

Here we obtain a joint test of all the interaction effects involving the `(2 vs 1)` comparison for `gender`. Because `gender` has only two levels, the `(2 vs 1)` contrast is the only reference category contrast possible. Therefore, we obtain a single joint test of all the interaction effects.

Clearly, the partial interaction effects are not interesting for this particular model. However, if our factors had more levels, the partial interaction effects would produce tests that are not available in the total interaction effects. For example, if our model included factors for four dosage levels and three races, then typing

```
. contrast ar.dose#race
```

would produce three joint tests, one for each of the reverse adjacent contrasts for dosage. Each of these tests would be a two-degree-of-freedom test because race has three levels.

Three-way and higher-order models

All the contrasts and tests that we reviewed above for two-way models can be used with models that have more terms. For instance, we could fit a three-way full factorial model by using the `anova` command:

```
. use http://www.stata-press.com/data/r12/cont3way
. anova y race##sex##group
```

We could then test the simple effects of `race` within each level of the interaction between `sex` and `group`:

```
. contrast race@sex#group
```

To see the reference category contrasts that decompose these simple effects, type

```
. contrast r.race@sex#group
```

We could test the three-way interaction effects by typing

```
. contrast race#sex#group
```

or the interaction effects for the interaction of `race` and `sex` by typing

```
. contrast race#sex
```

To see the individual reference category contrasts that decompose this interaction effect, type

```
. contrast r.race#r.sex
```

We could even obtain joint tests for the interaction of `race` and `sex` within each level of `group` by typing

```
. contrast race#sex@group
```

For tests of the main effects of each factor, we can type

```
. contrast race sex group
```

We can calculate the individual reference category contrasts that decompose these main effects:

```
. contrast r.race r.sex r.group
```

For the partial interaction effects, we could type

```
. contrast r.race#group
```

to obtain a joint test of the two-way interaction effects of `race` and `group` for each of the individual `r.race` contrasts.

We could type

```
. contrast r.race#sex#group
```

to obtain a joint test of all the three-way interaction terms for each of the individual `r.race` contrasts.

Contrast operators

`contrast` recognizes a set of contrast operators that are used to specify commonly used contrasts. When these operators are used, `contrast` will report a test for each individual contrast in addition to the joint test for the term. We have already seen a few of these, like `r.` and `ar.`, in the previous examples. Here we will take a closer look at each of the unweighted operators.

Here we use the cholesterol dataset and the one-way ANOVA model from the example in *One-way models*:

```
. use http://www.stata-press.com/data/r12/cholesterol
(Artificial cholesterol data)
. anova chol agegrp
  (output omitted)
```

The `margins` command reports the estimated cell means, $\widehat{\mu}_1$, ..., $\widehat{\mu}_5$, for each of the five age groups.

```
. margins agegrp
Adjusted predictions                            Number of obs   =         75
Expression   : Linear prediction, predict()
```

	Delta-method					
	Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
agegrp						
1	180.5198	2.666944	67.69	0.000	175.2926	185.7469
2	188.7233	2.666944	70.76	0.000	183.4962	193.9504
3	202.0608	2.666944	75.76	0.000	196.8337	207.2879
4	210.6704	2.666944	78.99	0.000	205.4433	215.8975
5	219.282	2.666944	82.22	0.000	214.0548	224.5091

Contrast operators provide an easy way to make certain types of comparisons of these cell means. We use the ordinal factor `agegrp` to demonstrate these operators because some types of contrasts are only meaningful when the levels of the factor have a natural ordering. We demonstrate these contrast operators using a one-way model; however, they are equally applicable to main effects, simple effects, and interactions for more complicated models.

Differences from a reference level (r.)

The `r.` operator specifies that each level of the attached factor variable be compared with a reference level. These are referred to as reference-level or reference-category contrasts (or effects), and `r.` is the reference-level operator.

In the following, we use the `r.` operator to test the effect of each category of age group when that category is compared with a reference category.

```
. contrast r.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(2 vs 1)	1	4.73	0.0330
(3 vs 1)	1	32.62	0.0000
(4 vs 1)	1	63.91	0.0000
(5 vs 1)	1	105.62	0.0000
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(2 vs 1)	8.203575	3.771628	.6812991	15.72585
(3 vs 1)	21.54105	3.771628	14.01878	29.06333
(4 vs 1)	30.15067	3.771628	22.6284	37.67295
(5 vs 1)	38.76221	3.771628	31.23993	46.28448

In the first table, the row labeled `(2 vs 1)` is a test of $\mu_2 = \mu_1$, a test that the mean cholesterol levels for the 10–19 age group (`agegrp` $= 1$) and the 20–29 age group (`agegrp` $= 2$) are equal. The tests in the next three rows are defined similarly. The row labeled `Joint` provides the joint test for these four hypotheses, which is just the test of the main effects of age group.

The second table provides the contrasts of each category with the reference category along with confidence intervals. The contrast in the row labeled `(2 vs 1)` is the difference in the cell means of the second age group and the first age group, $\widehat{\mu}_2 - \widehat{\mu}_1$.

The first level of a factor is the default reference level, but we can specify a different reference level by using the `b.` operator; see [U] **11.4.3.2 Base levels**. Here we use the last age group, `agegrp` $= 5$, instead of the first as the reference category. We also include the `nowald` option so that only the table of contrasts and their confidence intervals is produced.

```
. contrast rb5.agegrp, nowald
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(1 vs 5)	-38.76221	3.771628	-46.28448	-31.23993
(2 vs 5)	-30.55863	3.771628	-38.08091	-23.03636
(3 vs 5)	-17.22115	3.771628	-24.74343	-9.698877
(4 vs 5)	-8.611533	3.771628	-16.13381	-1.089257

Now the first row is labeled `(1 vs 5)` and is the difference in the cell means of the first and fifth age groups.

Differences from the next level (a.)

The `a.` operator specifies that each level of the attached factor variable be compared with the next level. These are referred to as adjacent contrasts (or effects), and `a.` is the adjacent operator. This operator is only meaningful with factor variables that have a natural ordering in the levels.

We can use the `a.` operator to perform tests that each level of age group differs from the next adjacent level.

```
. contrast a.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(1 vs 2)	1	4.73	0.0330
(2 vs 3)	1	12.51	0.0007
(3 vs 4)	1	5.21	0.0255
(4 vs 5)	1	5.21	0.0255
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(1 vs 2)	-8.203575	3.771628	-15.72585	-.6812991
(2 vs 3)	-13.33748	3.771628	-20.85976	-5.815204
(3 vs 4)	-8.60962	3.771628	-16.1319	-1.087345
(4 vs 5)	-8.611533	3.771628	-16.13381	-1.089257

In the first table, the row labeled `(1 vs 2)` tests the effect of belonging to the 10–19 age group instead of the 20–29 age group. Likewise, the rows labeled `(2 vs 3)`, `(3 vs 4)`, and `(4 vs 5)` are tests for the effects of being in the younger of the two age groups instead of the older one.

In the second table, the contrast in the row labeled `(1 vs 2)` is the difference in the cell means of the first and second age groups, $\widehat{\mu}_1 - \widehat{\mu}_2$. The contrasts in the other rows are defined similarly.

Differences from the previous level (ar.)

The ar. operator specifies that each level of the attached factor variable be compared with the previous level. These are referred to as reverse adjacent contrasts (or effects), and ar. is the reverse adjacent operator. As with the a. operator, this operator is only meaningful with factor variables that have a natural ordering in the levels.

In the following, we use the ar. operator to report tests for the individual reverse adjacent effects of agegrp.

```
. contrast ar.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(2 vs 1)	1	4.73	0.0330
(3 vs 2)	1	12.51	0.0007
(4 vs 3)	1	5.21	0.0255
(5 vs 4)	1	5.21	0.0255
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(2 vs 1)	8.203575	3.771628	.6812991	15.72585
(3 vs 2)	13.33748	3.771628	5.815204	20.85976
(4 vs 3)	8.60962	3.771628	1.087345	16.1319
(5 vs 4)	8.611533	3.771628	1.089257	16.13381

Here the Wald tests in the first table for the individual reverse adjacent effects are equivalent to the tests for the adjacent effects in the previous example. However, if we compare values of the contrasts in the bottom tables, we see the difference between the r. and the ar. operators. This time, the contrast in the first row is labeled (2 vs 1) and is the difference in the cell means of the second and first age groups, $\widehat{\mu}_2 - \widehat{\mu}_1$. This is the estimated effect of belonging to the 20–29 age group instead of the 10–19 age group. The remaining rows make similar comparisons to the previous level.

Differences from the grand mean (g.)

The g. operator specifies that each level of a factor variable be compared with the grand mean of all levels. For this operator, the grand mean is computed using a simple average of the cell means.

Here are the grand mean effects of agegrp:

```
. contrast g.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(1 vs mean)	1	68.42	0.0000
(2 vs mean)	1	23.36	0.0000
(3 vs mean)	1	0.58	0.4506
(4 vs mean)	1	19.08	0.0000
(5 vs mean)	1	63.65	0.0000
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(1 vs mean)	-19.7315	2.385387	-24.48901	-14.974
(2 vs mean)	-11.52793	2.385387	-16.28543	-6.770423
(3 vs mean)	1.809552	2.385387	-2.947953	6.567057
(4 vs mean)	10.41917	2.385387	5.661668	15.17668
(5 vs mean)	19.0307	2.385387	14.2732	23.78821

There are five age groups in our estimation sample. Thus the row labeled (1 vs mean) tests $\mu_1 = (\mu_1+\mu_2+\mu_3+\mu_4+\mu_5)/5$. The row labeled (2 vs mean) tests $\mu_2 = (\mu_1+\mu_2+\mu_3+\mu_4+\mu_5)/5$. The remaining rows perform similar tests for the third, fourth, and fifth age groups. In our example, the means for all age groups except group 3 (30–39 age group) are statistically different from the grand mean.

Differences from the mean of subsequent levels (h.)

The h. operator specifies that each level of the attached factor variable be compared with the mean of subsequent levels. These are referred to as Helmert contrasts (or effects), and h. is the Helmert operator. For this operator, the mean is computed using a simple average of the cell means. This operator is only meaningful with factor variables that have a natural ordering in the levels.

Here are the Helmert contrasts for agegrp:

```
. contrast h.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(1 vs >1)	1	68.42	0.0000
(2 vs >2)	1	50.79	0.0000
(3 vs >3)	1	15.63	0.0002
(4 vs 5)	1	5.21	0.0255
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(1 vs >1)	-24.66438	2.981734	-30.61126	-18.7175
(2 vs >2)	-21.94774	3.079522	-28.08965	-15.80583
(3 vs >3)	-12.91539	3.266326	-19.42987	-6.400905
(4 vs 5)	-8.611533	3.771628	-16.13381	-1.089257

The row labeled `(1 vs >1)` tests $\mu_1 = (\mu_2 + \mu_3 + \mu_4 + \mu_5)/4$, that is, that the cell mean for the youngest age group is equal to the average of the cell means for the older age groups. The row labeled `(2 vs >2)` tests $\mu_2 = (\mu_3 + \mu_4 + \mu_5)/3$. The tests in the other rows are defined similarly.

Differences from the mean of previous levels (j.)

The `j.` operator specifies that each level of the attached factor variable be compared with the mean of the previous levels. These are referred to as reverse Helmert contrasts (or effects), and `j.` is the reverse Helmert operator. For this operator, the mean is computed using a simple average of the cell means. This operator is only meaningful with factor variables that have a natural ordering in the levels.

Here are the reverse Helmert contrasts of `agegrp`:

```
. contrast j.agegrp
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(2 vs 1)	1	4.73	0.0330
(3 vs <3)	1	28.51	0.0000
(4 vs <4)	1	43.18	0.0000
(5 vs <5)	1	63.65	0.0000
Joint	4	35.02	0.0000
Residual	70		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp				
(2 vs 1)	8.203575	3.771628	.6812991	15.72585
(3 vs <3)	17.43927	3.266326	10.92479	23.95375
(4 vs <4)	20.2358	3.079522	14.09389	26.37771
(5 vs <5)	23.78838	2.981734	17.8415	29.73526

The row labeled `(2 vs 1)` tests $\mu_2 = \mu_1$, that is, that the cell means for the 20–29 and the 10–19 age groups are equal. The row labeled `(3 vs <3)` tests $\mu_3 = (\mu_1 + \mu_2)/2$, that is, that the cell mean for the 30–39 age group is equal to the average of the cell means for the 10–19 and 20–29 age groups. The tests in the remaining rows are defined similarly.

Orthogonal polynomials (p. and q.)

The p. and q. operators specify that orthogonal polynomials be applied to the attached factor variable. Orthogonal polynomial contrasts allow us to partition the effects of a factor variable into linear, quadratic, cubic, and higher-order polynomial components. The p. operator applies orthogonal polynomials using the values of the factor variable. The q. operator applies orthogonal polynomials using the level indices. If the level values of the factor variable are equally spaced, as with our agegrp variable, then the p. and q. operators yield the same result. These operators are only meaningful with factor variables that have a natural ordering in the levels.

Because agegrp has five levels, contrast can test the linear, quadratic, cubic, and quartic effects of agegrp.

```
. contrast p.agegrp, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(linear)	1	139.11	0.0000
(quadratic)	1	0.15	0.6962
(cubic)	1	0.37	0.5448
(quartic)	1	0.43	0.5153
Joint	4	35.02	0.0000
Residual	70		

The row labeled (linear) tests the linear effect of agegrp, the only effect that appears to be significant in this case.

The labels for our agegrp variable show the age ranges that correspond to each level.

```
. label list ages
ages:
           1 10-19
           2 20-29
           3 30-39
           4 40-59
           5 60-79
```

Notice that these groups do not have equal widths. Now let's refit our model using the agemidpt variable. The values of agemidpt indicate the midpoint of each age group that was defined by the agegrp variable and are, therefore, not equally spaced.

```
. anova chol agemidpt
                          Number of obs =      75     R-squared     =  0.6668
                          Root MSE      =  10.329     Adj R-squared =  0.6477
```

Source	Partial SS	df	MS	F	Prob > F
Model	14943.3997	4	3735.84993	35.02	0.0000
agemidpt	14943.3997	4	3735.84993	35.02	0.0000
Residual	7468.21971	70	106.688853		
Total	22411.6194	74	302.859722		

Now if we use the `q.` operator, we will obtain the same results as above because the level indices of `agemidpt` are equivalent to the values of `agegrp`.

```
. contrast q.agemidpt, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agemidpt			
(linear)	1	139.11	0.0000
(quadratic)	1	0.15	0.6962
(cubic)	1	0.37	0.5448
(quartic)	1	0.43	0.5153
Joint	4	35.02	0.0000
Residual	70		

However, if we use the `p.` operator, we will instead fit an orthogonal polynomial to the midpoint values.

```
. contrast p.agemidpt, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agemidpt			
(linear)	1	133.45	0.0000
(quadratic)	1	5.40	0.0230
(cubic)	1	0.05	0.8198
(quartic)	1	1.16	0.2850
Joint	4	35.02	0.0000
Residual	70		

Using the values of the midpoints, the quadratic effect is also significant at the 5% level.

❑ Technical note

We used the `noeffects` option when working with orthogonal polynomial contrasts. Apart from perhaps the sign of the contrast, the values of the individual contrasts are not meaningful for orthogonal polynomial contrasts. In addition, many textbooks provide tables with contrast coefficients that can be used to compute orthogonal polynomial contrasts where the levels of a factor are equally spaced. If we use these coefficients and calculate the contrasts manually with user-defined contrasts, as described below, the Wald tests for the polynomial terms will be equivalent, but the values of the individual contrasts will not necessarily match those that we obtain when using the polynomial contrast operator. When we use one of these contrast operators, an algorithm is used to calculate the coefficients of the polynomial contrast that will allow for unequal spacing in the levels of the factor as well as in the weights for the cell frequencies (when using `pw.` or `qw.`), as described in *Methods and formulas*.

❑

User-defined contrasts

In the previous examples, we performed tests using contrast operators. When there is not a contrast operator available to calculate the contrast in which we are interested, we can specify custom contrasts.

Here we fit a one-way model for cholesterol on the factor `race`, which has three levels:

```
. label list race
race:
           1 black
           2 white
           3 other
. anova chol race
                          Number of obs =      75     R-squared     =  0.0299
                          Root MSE      = 17.3775     Adj R-squared =  0.0029
```

Source	Partial SS	df	MS	F	Prob > F
Model	669.278235	2	334.639117	1.11	0.3357
race	669.278235	2	334.639117	1.11	0.3357
Residual	21742.3412	72	301.976961		
Total	22411.6194	74	302.859722		

`margins` calculates the estimated cell mean cholesterol level for each race:

```
. margins race
Adjusted predictions                                  Number of obs   =         75
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
race						
1	204.4279	3.475497	58.82	0.000	197.6161	211.2398
2	197.6132	3.475497	56.86	0.000	190.8014	204.425
3	198.7127	3.475497	57.18	0.000	191.9008	205.5245

Suppose we want to test the following linear combination:

$$\sum_{i=1}^{3} c_i \mu_i$$

where μ_i is the cell mean of `chol` when `race` is equal to its ith level (the means estimated using `margins` above). Assuming the c_i elements sum to zero, this linear combination is a contrast. We can specify this type of custom contrast by using the following syntax:

$$\{\texttt{race}\ c_1\ c_2\ c_3\}$$

The null hypothesis for the test of the main effects of `race` is

$$H_{0_{\text{race}}}\colon \mu_1 = \mu_2 = \mu_3$$

Although $H_{0_{\text{race}}}$ can be tested using any of several different contrasts on the cell means, we will test it by comparing the second and third cell means with the first. To test that the cell means for blacks and whites are equal, $\mu_1 = \mu_2$, we can specify the contrast

```
{race -1 1 0}
```

To test that the cell means for blacks and other races are equal, $\mu_1 = \mu_3$, we can specify the contrast

```
{race -1 0 1}
```

We can use both in a single call to `contrast`.

```
. contrast {race -1 1 0} {race -1 0 1}
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(1)	1	1.92	0.1699
(2)	1	1.35	0.2488
Joint	2	1.11	0.3357
Residual	72		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(1)	-6.814717	4.915095	-16.61278	2.983345
(2)	-5.715261	4.915095	-15.51332	4.082801

The row labeled `(1)` is the test for $\mu_1 = \mu_2$, the first specified contrast. The row labeled `(2)` is the test for $\mu_1 = \mu_3$, the second specified contrast. The row labeled `Joint` is the overall test for the main effects of `race`.

Now let's fit a model with two factors, race and age group:

```
. anova chol race##agegrp
```

Number of obs = 75 R-squared = 0.7524
Root MSE = 9.61785 Adj R-squared = 0.6946

Source	Partial SS	df	MS	F	Prob > F
Model	16861.438	14	1204.38843	13.02	0.0000
race	669.278235	2	334.639117	3.62	0.0329
agegrp	14943.3997	4	3735.84993	40.39	0.0000
race#agegrp	1248.76005	8	156.095006	1.69	0.1201
Residual	5550.18143	60	92.5030238		
Total	22411.6194	74	302.859722		

The null hypothesis for the test of the main effects of `race` is now

$$H_{0_{\text{race}}}\colon \mu_{1\cdot} = \mu_{2\cdot} = \mu_{3\cdot}$$

where $\mu_{i\cdot}$ is the marginal mean of `chol` when `race` is equal to its ith level.

We can use the same syntax as above to perform this test by specifying contrasts on the marginal means of `race`:

```
. contrast {race -1 1 0} {race -1 0 1}
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(1)	1	6.28	0.0150
(2)	1	4.41	0.0399
Joint	2	3.62	0.0329
Residual	60		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(1)	-6.814717	2.720339	-12.2562	-1.37323
(2)	-5.715261	2.720339	-11.15675	-.2737739

Custom contrasts may be specified on the cell means of interactions, too. Here we use `margins` to calculate the mean of `chol` for each cell in the interaction of `race` and `agegrp`:

```
. margins race#agegrp
Adjusted predictions                              Number of obs   =         75
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
race#agegrp						
1 1	179.2309	4.301233	41.67	0.000	170.8006	187.6611
1 2	196.4777	4.301233	45.68	0.000	188.0474	204.908
1 3	210.6694	4.301233	48.98	0.000	202.2391	219.0996
1 4	214.097	4.301233	49.78	0.000	205.6668	222.5273
1 5	221.6646	4.301233	51.54	0.000	213.2344	230.0949
2 1	186.0727	4.301233	43.26	0.000	177.6425	194.503
2 2	184.6714	4.301233	42.93	0.000	176.2411	193.1017
2 3	196.2633	4.301233	45.63	0.000	187.833	204.6936
2 4	209.9953	4.301233	48.82	0.000	201.5651	218.4256
2 5	211.0633	4.301233	49.07	0.000	202.633	219.4935
3 1	176.2556	4.301233	40.98	0.000	167.8254	184.6859
3 2	185.0209	4.301233	43.02	0.000	176.5906	193.4512
3 3	199.2498	4.301233	46.32	0.000	190.8195	207.68
3 4	207.9189	4.301233	48.34	0.000	199.4887	216.3492
3 5	225.118	4.301233	52.34	0.000	216.6877	233.5483

Now we are interested in testing the following linear combination of these cell means:

$$\sum_{i=1}^{3}\sum_{j=1}^{5} c_{ij}\mu_{ij}$$

We can specify this type of custom contrast using the following syntax:

{race#agegrp c_{11} c_{12} ... c_{15} c_{21} c_{22} ... c_{25} c_{31} c_{32} ... c_{35}}

Because the marginal means of chol for each level of race are linear combinations of the cell means, we can compose the test for the main effects of race in terms of the cell means directly. The constraint that the marginal means for blacks and whites are equal, $\mu_{1\cdot} = \mu_{2\cdot}$, translates to the following constraint on the cell means:

$$\frac{1}{5}(\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15}) = \frac{1}{5}(\mu_{21} + \mu_{22} + \mu_{23} + \mu_{24} + \mu_{25})$$

Ignoring the common factor, we can specify this contrast as

```
{race#agegrp -1 -1 -1 -1 -1 1 1 1 1 1 0 0 0 0 0}
```

contrast will fill in the trailing zeros for us if we neglect to specify them, so

```
{race#agegrp -1 -1 -1 -1 -1 1 1 1 1 1}
```

is also allowed. The other constraint, $\mu_{1\cdot} = \mu_{3\cdot}$, translates to

$$\frac{1}{5}(\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15}) = \frac{1}{5}(\mu_{31} + \mu_{32} + \mu_{33} + \mu_{34} + \mu_{35})$$

This can be specified to contrast as

```
{race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 1 1 1 1 1}
```

The following call to contrast yields the same test results as above.

```
. contrast {race#agegrp -1 -1 -1 -1 -1 1 1 1 1 1}
>          {race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 1 1 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race#agegrp			
(1) (1)	1	6.28	0.0150
(2) (2)	1	4.41	0.0399
Joint	2	3.62	0.0329
Residual	60		

The row labeled (1) (1) is the test for

$$\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15} = \mu_{21} + \mu_{22} + \mu_{23} + \mu_{24} + \mu_{25}$$

It was the first specified contrast. The row labeled (2) (2) is the test for

$$\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15} = \mu_{31} + \mu_{32} + \mu_{33} + \mu_{34} + \mu_{35}$$

It was the second specified contrast. The row labeled Joint tests (1) (1) and (2) (2) simultaneously.

We used the `noeffects` option above to suppress the table of contrasts. We can omit the $1/5$ from the equations for $\mu_{1\cdot} = \mu_{2\cdot}$ and $\mu_{1\cdot} = \mu_{3\cdot}$ and still obtain the appropriate tests. However, if we want to calculate the differences in the marginal means, we must include the $1/5 = 0.2$ on each of the contrast coefficients as follows:

```
. contrast {race#agegrp -0.2 -0.2 -0.2 -0.2 -0.2
                         0.2  0.2  0.2  0.2  0.2}
           {race#agegrp -0.2 -0.2 -0.2 -0.2 -0.2
                           0    0    0    0    0
                         0.2  0.2  0.2  0.2  0.2}
```

So far, we have reproduced the reference category contrasts by specifying user-defined contrasts on the marginal means and then on the cell means. For this test, it would have been easier to use the `r.` contrast operator:

```
. contrast r.race, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(2 vs 1)	1	6.28	0.0150
(3 vs 1)	1	4.41	0.0399
Joint	2	3.62	0.0329
Residual	60		

In most cases, we can use contrast operators to perform tests. However, if we want to compare, for instance, the second and third age groups with the fourth and fifth age groups with the test

$$\frac{1}{2}(\mu_{\cdot 2} + \mu_{\cdot 3}) = \frac{1}{2}(\mu_{\cdot 4} + \mu_{\cdot 5})$$

there is not a contrast operator that corresponds to this particular contrast. A custom contrast is necessary.

```
. contrast {agegrp 0 -0.5 -0.5 0.5 0.5}
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp	1	62.19	0.0000
Residual	60		

	Contrast	Std. Err.	[95% Conf.	Interval]
agegrp (1)	19.58413	2.483318	14.61675	24.5515

Empty cells

An empty cell is a combination of the levels of factor variables that is not observed in the estimation sample. In the previous examples, we have seen data with three levels of `race`, five levels of `agegrp`, and all level combinations of `race` and `agegrp` present. Suppose there are no observations for white individuals in the second age group (ages 20–29).

```
. use http://www.stata-press.com/data/r12/cholesterol2
(Artificial cholesterol data, empty cells)
. label list
race:
           1 black
           2 white
           3 other
ages:
           1 10-19
           2 20-29
           3 30-39
           4 40-59
           5 60-79
. regress chol race##agegrp
note: 2.race#2.agegrp identifies no observations in the sample
```

Now let's use `contrast` to test the main effects of `race`:

```
. contrast race
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race	(not testable)		
Residual	56		

By "not testable", `contrast` means that it cannot form a test for the main effects of `race` based on estimable functions of the model coefficients. `agegrp` has five levels, so `contrast` constructs an estimate of the ith margin for `race` as

$$\widehat{\mu}_{i\cdot} = \frac{1}{5}\sum_{j=1}^{5}\widehat{\mu}_{ij} = \widehat{\mu}_0 + \widehat{\alpha}_i + \frac{1}{5}\sum_{j=1}^{5}\left\{\widehat{\beta}_j + \widehat{(\alpha\beta)}_{ij}\right\}$$

but $\widehat{(\alpha\beta)}_{22}$ was constrained to zero because of the empty cell, so $\widehat{\mu}_{2\cdot}$ is not an estimable function of the model coefficients.

See *Estimable functions* in *Methods and formulas* of [R] **margins** for a technical description of estimable functions. The `emptycells(reweight)` option causes `contrast` to estimate $\mu_{2\cdot}$ by

$$\widehat{\mu}_{2\cdot} = \frac{\widehat{\mu}_{21} + \widehat{\mu}_{23} + \widehat{\mu}_{24} + \widehat{\mu}_{25}}{4}$$

which is an estimable function of the model coefficients.

```
. contrast race, emptycells(reweight)
Contrasts of marginal linear predictions
Margins      : asbalanced
Empty cells  : reweight
```

	df	F	P>F
race	2	3.17	0.0498
Residual	56		

We can reconstruct the effect of the `emptycells(reweight)` option by using custom contrasts.

```
. contrast {race#agegrp -4 -4 -4 -4 -4 5 0 5 5 5}
>          {race#agegrp -1 -1 -1 -1 -1 0 0 0 0 0 1 1 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race#agegrp			
(1) (1)	1	1.06	0.3080
(2) (2)	1	2.37	0.1291
Joint	2	3.17	0.0498
Residual	56		

The row labeled `(1) (1)` is the test for

$$\frac{1}{5}(\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15}) = \frac{1}{4}(\mu_{21}+\mu_{23}+\mu_{24}+\mu_{25})$$

It was the first specified contrast. The row labeled `(2) (2)` is the test for

$$\mu_{11}+\mu_{12}+\mu_{13}+\mu_{14}+\mu_{15} = \mu_{31}+\mu_{32}+\mu_{33}+\mu_{34}+\mu_{35}$$

It was the second specified contrast. The row labeled `Joint` is the overall test of the main effects of `race`.

Empty cells, ANOVA style

Let's refit the linear model from the previous example with `anova` to compare with `contrast`'s test for the main effects of `race`.

```
. anova chol race##agegrp
```

```
                  Number of obs =      70     R-squared     =  0.7582
                  Root MSE      = 9.47055     Adj R-squared =  0.7021
```

Source	Partial SS	df	MS	F	Prob > F
Model	15751.6113	13	1211.66241	13.51	0.0000
race	305.49046	2	152.74523	1.70	0.1914
agegrp	14387.8559	4	3596.96397	40.10	0.0000
race#agegrp	795.807574	7	113.686796	1.27	0.2831
Residual	5022.71559	56	89.6913498		
Total	20774.3269	69	301.077201		

`contrast` and `anova` handled the empty cell differently; the F statistic reported by `contrast` was 3.17, but `anova` reported 1.70. To see how they differ, consider the following table of the cell means and margins for our situation.

		agegrp					
		1	2	3	4	5	
race	1	μ_{11}	μ_{12}	μ_{13}	μ_{14}	μ_{15}	$\mu_{1\cdot}$
	2	μ_{21}		μ_{23}	μ_{24}	μ_{25}	
	3	μ_{31}	μ_{32}	μ_{33}	μ_{34}	μ_{35}	$\mu_{3\cdot}$
		$\mu_{\cdot 1}$		$\mu_{\cdot 3}$	$\mu_{\cdot 4}$	$\mu_{\cdot 5}$	

For testing the main effects of `race`, we know that we will be testing the equality of the marginal means for rows 1 and 3, that is, $\mu_{1\cdot} = \mu_{3\cdot}$. This translates into the following constraint:

$$\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15} = \mu_{31} + \mu_{32} + \mu_{33} + \mu_{34} + \mu_{35}$$

Because row 2 contains an empty cell in column 2, `anova` dropped column 2 and tested the equality of the marginal mean for row 2 with the average of the marginal means from rows 1 and 3, using only the remaining cell means. This translates into the following constraint:

$$2(\mu_{21} + \mu_{23} + \mu_{24} + \mu_{25}) = \mu_{11} + \mu_{13} + \mu_{14} + \mu_{15} + \mu_{31} + \mu_{33} + \mu_{34} + \mu_{35} \qquad (1)$$

Now that we know the constraints that `anova` used to test for the main effects of `race`, we can use custom contrasts to reproduce the `anova` test result.

```
. contrast {race#agegrp -1 -1 -1 -1 -1  0 0  0  0  0 1 1 1 1 1}
>          {race#agegrp  1  0  1  1  1 -2 0 -2 -2 -2 1 0 1 1 1}, noeffects
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race#agegrp			
(1) (1)	1	2.37	0.1291
(2) (2)	1	1.03	0.3138
Joint	2	1.70	0.1914
Residual	56		

The row labeled `(1) (1)` is the test for $\mu_{1\cdot} = \mu_{3\cdot}$; it was the first specified contrast. The row labeled `(2) (2)` is the test for the constraint in (1); it was the second specified contrast. The row labeled `Joint` is an overall test for the main effects of `race`.

Nested effects

`contrast` has the `|` operator for computing simple effects when the levels of one factor are nested within the levels of another. Here is a fictional example where we are interested in the effect of five methods of teaching algebra on students' scores for the math portion of the SAT. Suppose three algebra classes are randomly sampled from classes using each of the five methods so that `class` is nested in `method` as demonstrated in the following tabulation.

```
. use http://www.stata-press.com/data/r12/SAT
(Artificial SAT data)
. tabulate class method
```

class	method 1	2	3	4	5	Total
1	5	0	0	0	0	5
2	5	0	0	0	0	5
3	5	0	0	0	0	5
4	0	5	0	0	0	5
5	0	5	0	0	0	5
6	0	5	0	0	0	5
7	0	0	5	0	0	5
8	0	0	5	0	0	5
9	0	0	5	0	0	5
10	0	0	0	5	0	5
11	0	0	0	5	0	5
12	0	0	0	5	0	5
13	0	0	0	0	5	5
14	0	0	0	0	5	5
15	0	0	0	0	5	5
Total	15	15	15	15	15	75

We will consider `method` as fixed and `class` nested in `method` as random. To use `class` nested in `method` as the error term for `method`, we can specify the following `anova` model:

```
. anova score method / class|method /
```

```

```

Source	Partial SS	df	MS	F	Prob > F
Model	980312	14	70022.2857	13.56	0.0000
method	905872	4	226468	30.42	0.0000
class|method	74440	10	7444		
class|method	74440	10	7444	1.44	0.1845
Residual	309760	60	5162.66667		
Total	1290072	74	17433.4054		

Like `anova`, `contrast` allows the `|` operator, which specifies that one variable is nested in the levels of another. We can use `contrast` to test the main effects of `method` and the simple effects of `class` within `method`.

```
. contrast method class|method
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
method	(not testable)		
class|method			
1	2	2.80	0.0687
2	2	0.91	0.4089
3	2	1.10	0.3390
4	2	0.22	0.8025
5	2	2.18	0.1221
Joint	10	1.44	0.1845
Residual	60		

Although `contrast` was able to perform the individual tests for the simple effects of `class` within `method`, empty cells in the interaction between `method` and `class` prevented `contrast` from testing for a main effect of `method`. Here we add the `emptycells(reweight)` option so that `contrast` can take the empty cells into account when computing the marginal means for `method`.

```
. contrast method class|method, emptycells(reweight)
Contrasts of marginal linear predictions
Margins      : asbalanced
Empty cells  : reweight
```

	df	F	P>F
method	4	43.87	0.0000
class|method			
1	2	2.80	0.0687
2	2	0.91	0.4089
3	2	1.10	0.3390
4	2	0.22	0.8025
5	2	2.18	0.1221
Joint	10	1.44	0.1845
Residual	60		

Now `contrast` does report a test for the main effects of `method`. However, if we compare this with the `anova` results, we will see that the results are different. They are different because `contrast` uses the residual error term to compute the F test by default. Using notation similar to `anova`, we can use the `/` operator to specify a different error term for the test. Therefore, we can reproduce the test of main effects from our `anova` command by typing

```
. contrast method / class|method /, emptycells(reweight)
Contrasts of marginal linear predictions
Margins      : asbalanced
Empty cells  : reweight
```

	df	F	P>F
method	4	30.42	0.0000
class|method	10	(denominator)	
class|method			
1	2	2.80	0.0687
2	2	0.91	0.4089
3	2	1.10	0.3390
4	2	0.22	0.8025
5	2	2.18	0.1221
Joint	10	1.44	0.1845
Residual	60		

Multiple comparisons

We have seen that `contrast` can report the individual linear combinations that make up the requested effects. Depending upon the specified option, `contrast` will report confidence intervals, p-values, or both in the effects table. By default, the reported confidence intervals and p-values are not adjusted for multiple comparisons. Use the `mcompare()` option to adjust the confidence intervals and p-values for multiple comparisons of the individual effects.

Let's compute the grand mean effects of `race` using the `g.` operator. We also specify the `mcompare(bonferroni)` option to compute p-values and confidence intervals using Bonferroni's adjustment.

```
. use http://www.stata-press.com/data/r12/cholesterol
(Artificial cholesterol data)
. anova chol race##agegrp
  (output omitted )
. contrast g.race, mcompare(bonferroni)
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F	Bonferroni P>F
race				
(1 vs mean)	1	7.07	0.0100	0.0301
(2 vs mean)	1	2.82	0.0982	0.2947
(3 vs mean)	1	0.96	0.3312	0.9936
Joint	2	3.62	0.0329	
Residual	60			

```
Note: Bonferroni-adjusted p-values are reported for tests
      on individual contrasts only.
```

	Number of Comparisons
race	3

	Contrast	Std. Err.	Bonferroni [95% Conf.	Interval]
race				
(1 vs mean)	4.17666	1.570588	.3083743	8.044945
(2 vs mean)	-2.638058	1.570588	-6.506343	1.230227
(3 vs mean)	-1.538602	1.570588	-5.406887	2.329684

The last table reports a Bonferroni-adjusted confidence interval for each individual contrast. (Use the `effects` option to add p-values to the last table.) The first table includes a Bonferroni-adjusted p-value for each test that is not a joint test.

Joint tests are never adjusted for multiple comparisons. For example,

```
. contrast race@agegrp, mcompare(bonferroni)
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race@agegrp			
1	2	1.37	0.2620
2	2	2.44	0.0958
3	2	3.12	0.0512
4	2	0.53	0.5889
5	2	2.90	0.0628
Joint	10	2.07	0.0409
Residual	60		

```
Note: Bonferroni-adjusted p-values are reported
      for tests on individual contrasts only.
```

	Number of Comparisons
race@agegrp	10

	Contrast	Std. Err.	Bonferroni [95% Conf.	Interval]
race@agegrp				
(2 vs base) 1	6.841855	6.082862	-10.88697	24.57068
(2 vs base) 2	-11.80631	6.082862	-29.53513	5.922513
(2 vs base) 3	-14.40607	6.082862	-32.13489	3.322751
(2 vs base) 4	-4.101691	6.082862	-21.83051	13.62713
(2 vs base) 5	-10.60137	6.082862	-28.33019	7.127448
(3 vs base) 1	-2.975244	6.082862	-20.70407	14.75358
(3 vs base) 2	-11.45679	6.082862	-29.18561	6.272031
(3 vs base) 3	-11.41958	6.082862	-29.1484	6.309244
(3 vs base) 4	-6.17807	6.082862	-23.90689	11.55075
(3 vs base) 5	3.453375	6.082862	-14.27545	21.1822

Here we have five tests of simple effects with two degrees of freedom each. No Bonferroni-adjusted p-values are available for these tests, but the confidence intervals for the individual contrasts are adjusted.

Unbalanced data

By default, `contrast` treats all factors as balanced when computing marginal means. By balanced, we mean that `contrast` assumes an equal number of observations in each level of each factor and an equal number of observations in each cell of each interaction. If our data are balanced, there is no issue. If, however, our data are not balanced, we might prefer that `contrast` use the actual cell frequencies from our data in computing marginal means. We instruct `contrast` to use observed frequencies by adding the `asobserved` option.

Even if our data are unbalanced, we might still want `contrast` to compute balanced marginal means. It depends on what we want to test and what our data represent. If we have data from a designed experiment that started with an equal number of males and females but the data became unbalanced because the data from a few males were unusable, we might still want our margins computed as though the data were balanced. If, however, we have a representative sample of individuals from Los Angeles with 40% of European descent, 34% African-American, 25% Hispanic, and 1% Australian, we probably want our margins computed using these representative frequencies. We do not want Australians receiving the same weight as Europeans.

The following examples will use an unbalanced version of our dataset.

```
. use http://www.stata-press.com/data/r12/cholesterol3
(Artificial cholesterol data, unbalanced)
. tab race agegrp
```

	agegrp					
race	10-19	20-29	30-39	40-59	60-79	Total
black	1	5	5	4	3	18
white	4	5	7	4	4	24
other	3	7	6	5	4	25
Total	8	17	18	13	11	67

The row labeled `Total` gives observed cell frequencies for age group. These can be obtained by summing frequencies from the cells in the corresponding column. In this respect, we can also refer to them as marginal frequencies. We use the terms marginal frequencies and cell frequencies interchangeably below.

We begin by fitting the two-factor model with an interaction.

```
. anova chol race##agegrp
```

Number of obs =	67		R-squared =		0.8179

Residual	3647.2774	52	70.13995		
Total	20027.27	66	303.443485		

Using observed cell frequencies

Recall that the marginal means are computed from the cell means. Treating the factors as balanced yields the following marginal means for `race`:

$$\eta_{1\cdot} = \frac{1}{5}(\mu_{11} + \mu_{12} + \mu_{13} + \mu_{14} + \mu_{15})$$

$$\eta_{2\cdot} = \frac{1}{5}(\mu_{21} + \mu_{22} + \mu_{23} + \mu_{24} + \mu_{25})$$

$$\eta_{3\cdot} = \frac{1}{5}(\mu_{31} + \mu_{32} + \mu_{33} + \mu_{34} + \mu_{35})$$

If we have a fixed population and unbalanced cells, then the $\eta_{i\cdot}$ do not represent population means. If, however, our data are representative of the population, we can use the frequencies from our estimation sample to estimate the population marginal means, denoted $\mu_{i\cdot}$.

Here are the results of testing for a main effect of `race`, treating all the factors as balanced.

```
. contrast r.race
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(2 vs 1)	1	3.28	0.0757
(3 vs 1)	1	1.50	0.2263
Joint	2	1.64	0.2029
Residual	52		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(2 vs 1)	-5.324254	2.93778	-11.21934	.5708338
(3 vs 1)	-3.596867	2.93778	-9.491955	2.298221

The row labeled `(2 vs 1)` is the test for $\eta_{2\cdot} = \eta_{1\cdot}$. The row labeled `(3 vs 1)` is the test for $\eta_{3\cdot} = \eta_{1\cdot}$.

If the observed marginal frequencies are representative of the distribution of the levels of `agegrp`, we can use them to form the marginal means of `chol` for each of the levels of `race` from the cell means.

$$\mu_{1\cdot} = \frac{1}{67}(8\mu_{11} + 17\mu_{12} + 18\mu_{13} + 13\mu_{14} + 11\mu_{15})$$

$$\mu_{2\cdot} = \frac{1}{67}(8\mu_{21} + 17\mu_{22} + 18\mu_{23} + 13\mu_{24} + 11\mu_{25})$$

$$\mu_{3\cdot} = \frac{1}{67}(8\mu_{31} + 17\mu_{32} + 18\mu_{33} + 13\mu_{34} + 11\mu_{35})$$

Here are the results of testing for the main effects of `race`, using the observed marginal frequencies:

```
. contrast r.race, asobserved
Contrasts of marginal linear predictions
Margins      : asobserved
```

	df	F	P>F
race			
(2 vs 1)	1	7.25	0.0095
(3 vs 1)	1	3.89	0.0538
Joint	2	3.74	0.0304
Residual	52		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(2 vs 1)	-7.232433	2.686089	-12.62246	-1.842402
(3 vs 1)	-5.231198	2.651203	-10.55123	.0888295

The row labeled `(2 vs 1)` is the test for $\mu_{2\cdot} = \mu_{1\cdot}$. The row labeled `(3 vs 1)` is the test for $\mu_{3\cdot} = \mu_{1\cdot}$. Both tests were insignificant when we tested the cell means resulting from balanced frequencies; however, when we tested the cell means from observed frequencies, the first test is significant beyond the 5% level (and the second test is nearly so).

Here we reproduce the results of the `asobserved` option with custom contrasts. Because we are modifying the way that the marginal means are constructed from the cell means, we will specify the contrasts on the predicted cell means. We use macro expansion, `=`*exp*, to evaluate the fractions instead of approximating them with decimals. Macro expansion guarantees that the contrast coefficients sum to zero. For more information, see *Macro expansion operators and function* in [P] **macro**.

```
. contrast {race#agegrp -‘=8/67’ -‘=17/67’ -‘=18/67’ -‘=13/67’ -‘=11/67’
>                        ‘=8/67’  ‘=17/67’  ‘=18/67’  ‘=13/67’  ‘=11/67’}
>          {race#agegrp -‘=8/67’ -‘=17/67’ -‘=18/67’ -‘=13/67’ -‘=11/67’
>                         0         0         0         0         0
>                        ‘=8/67’  ‘=17/67’  ‘=18/67’  ‘=13/67’  ‘=11/67’}
Contrasts of marginal linear predictions

(2) (2)	-5.231198	2.651203	-10.55123	.0888295

Weighted contrast operators

`contrast` provides observation-weighted versions of five of the contrast operators—`gw.`, `hw.`, `jw.`, `pw.`, and `qw.`. The first three of these operators perform comparisons of means across cells, and like the marginal means just discussed, these means can be computed in two ways: 1) as though the cell frequencies were equal or 2) using the observed cell frequencies from the estimation sample. The weighted operators provide versions of the standard (as balanced) operators that weight these means by their cell frequencies. The two orthogonal polynomial operators involve similar adjustments for weighting.

Let’s examine what this means by using the `gw.` operator. The `gw.` operator is a weighted version of the `g.` operator. The `gw.` operator computes the grand mean using the cell frequencies for `race` obtained from the model fit.

Here we test the effects of `race`, comparing each level with the weighted grand mean but otherwise treating the factors as balanced in the marginal mean calculations.

```
. contrast gw.race
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(1 vs mean)	1	2.78	0.1014
(2 vs mean)	1	2.06	0.1573
(3 vs mean)	1	0.06	0.8068
Joint	2	1.64	0.2029
Residual	52		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(1 vs mean)	3.24931	1.948468	-.6605779	7.159198
(2 vs mean)	-2.074944	1.44618	-4.976915	.8270276
(3 vs mean)	-.347557	1.414182	-3.18532	2.490206

The observed marginal frequencies of `race` are 18, 24, and 25. Thus the row labeled `(1 vs mean)` tests $\eta_{1\cdot} = (18\eta_{1\cdot}+24\eta_{2\cdot}+25\eta_{3\cdot})/67$; the row labeled `(2 vs mean)` tests $\eta_{2\cdot} = (18\eta_{1\cdot}+24\eta_{2\cdot}+25\eta_{3\cdot})/67$; and the row labeled `(3 vs mean)` tests $\eta_{3\cdot} = (18\eta_{1\cdot} + 24\eta_{2\cdot} + 25\eta_{3\cdot})/67$.

Now we reproduce the above results using custom contrasts. We are weighting the calculation of the grand mean from the marginal means for each of the races, but we are not weighting the calculation of the marginal means themselves. Therefore, we can specify the custom contrast on the marginal means for `race` instead of on the cell means.

```
. contrast {race  `=49/67' -`=24/67' -`=25/67'}
>          {race -`=18/67'  `=43/67' -`=25/67'}
>          {race -`=18/67' -`=24/67'  `=42/67'}
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
race			
(1)	1	2.78	0.1014
(2)	1	2.06	0.1573
(3)	1	0.06	0.8068
Joint	2	1.64	0.2029
Residual	52		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(1)	3.24931	1.948468	-.6605779	7.159198
(2)	-2.074944	1.44618	-4.976915	.8270276
(3)	-.347557	1.414182	-3.18532	2.490206

Now we will test for each `race` the difference between the marginal mean and the weighted grand mean, treating the factors as observed in the marginal mean calculations.

```
. contrast gw.race, asobserved wald ci
Contrasts of marginal linear predictions
Margins      : asobserved
```

	df	F	P>F
race			
(1 vs mean)	1	6.81	0.0118
(2 vs mean)	1	3.74	0.0587
(3 vs mean)	1	0.26	0.6099
Joint	2	3.74	0.0304
Residual	52		

	Contrast	Std. Err.	[95% Conf.	Interval]
race				
(1 vs mean)	4.542662	1.740331	1.050432	8.034891
(2 vs mean)	-2.689771	1.39142	-5.481859	.1023172
(3 vs mean)	-.6885363	1.341261	-3.379973	2.002901

The row labeled `(1 vs mean)` tests $\mu_{1.} = (18\mu_{1.} + 24\mu_{2.} + 25\mu_{3.})/67$; the row labeled `(2 vs mean)` tests $\mu_{2.} = (18\mu_{1.} + 24\mu_{2.} + 25\mu_{3.})/67$; and the row labeled `(3 vs mean)` tests $\mu_{3.} = (18\mu_{1.} + 24\mu_{2.} + 25\mu_{3.})/67$.

Here we use a custom contrast to reproduce the above result testing $\mu_{1.} = (18\mu_{1.} + 24\mu_{2.} + 25\mu_{3.})/67$. Because both the calculation of the marginal means and the calculation of the grand mean are adjusted, we specify the custom contrast on the cell means.

```
. contrast {race#agegrp  `=49/67*8/67'  `=49/67*17/67'  `=49/67*18/67'
>                        `=49/67*13/67'  `=49/67*11/67'
>                       -`=24/67*8/67' -`=24/67*17/67' -`=24/67*18/67'
>                       -`=24/67*13/67' -`=24/67*11/67'
>                       -`=25/67*8/67' -`=25/67*17/67' -`=25/67*18/67'
>                       -`=25/67*13/67' -`=25/67*11/67'}, nowald
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	Contrast	Std. Err.	[95% Conf.	Interval]
race#agegrp				
(1) (1)	4.542662	1.740331	1.050432	8.034891

The Helmert and reverse Helmert contrasts also involve calculating averages of the marginal means; therefore, weighted versions of these parameters are available as well. The `hw.` operator is a weighted version of the `h.` operator that computes the mean of the subsequent levels using the cell frequencies obtained from the model fit. The `jw.` operator is a weighted version of the `j.` operator that computes the mean of the previous levels using the cell frequencies obtained from the model fit.

For orthogonal polynomials, we can use the `pw.` and `qw.` operators, which are the weighted versions of the `p.` and `q.` operators. In this case, the cell frequencies from the model fit are used in the calculation of the orthogonal polynomial contrast coefficients.

Testing factor effects on slopes

For linear models where the independent variables are all factor variables, the linear prediction at fixed levels of the factor variables turns out to be a cell mean. With these models, `contrast` computes and tests the effects of the factor variables on the expected mean of the dependent variable. When factor variables are interacted with continuous variables, `contrast` distinguishes factor effects on the intercept from factor effects on the slope.

Here we have 1980 census data including information on the birth rate (`brate`), the median age (`medage`), and the region of the country (`region`) for each of the 50 states. We can fit an ANCOVA model for `brate` using main effects of the factor variable `region` and the continuous variable `medage`.

```
. use http://www.stata-press.com/data/r12/census3
(1980 Census data by state)
. label list cenreg
cenreg:
           1 NE
           2 N Cntrl
           3 South
           4 West
. anova brate i.region c.medage
```

	Number of obs = 50	R-squared = 0.8264
	Root MSE = 12.7575	Adj R-squared = 0.8110

(4 vs 1)	21.71328	6.755616	8.106774	35.31979

Let's add the interaction between `region` and `medage` to the model.

```
. anova brate region##c.medage
```

Number of obs = 50 R-squared = 0.9000
Root MSE = 10.0244 Adj R-squared = 0.8833

Source	Partial SS	df	MS	F	Prob > F
Model	37976.3149	7	5425.18784	53.99	0.0000
region	3405.07044	3	1135.02348	11.30	0.0000
medage	5279.71448	1	5279.71448	52.54	0.0000
region#medage	3103.45597	3	1034.48532	10.29	0.0000
Residual	4220.5051	42	100.488217		
Total	42196.82	49	861.159592		

The parameterization for the expected value of `brate` as a function of `region` and `medage` is given by

$$E(\texttt{brate}|\texttt{region} = i, \texttt{medage}) = \alpha_0 + \alpha_i + \beta_0\texttt{medage} + \beta_i\texttt{medage}$$

where α_0 is the intercept and β_0 is the slope of `medage`. We are modeling the effects of `region` in two different ways. The α_i parameters measure the effect of `region` on the intercept, and the β_i parameters measure the effect of `region` on the slope of `medage`.

`contrast` computes and tests effects on slopes separately from effects on intercepts. First, we will compute the reference category effects of `region` on the intercept:

```
. contrast r.region
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
region			
(2 vs 1)	1	0.09	0.7691
(3 vs 1)	1	0.01	0.9389
(4 vs 1)	1	8.50	0.0057
Joint	3	11.30	0.0000
Residual	42		

	Contrast	Std. Err.	[95% Conf.	Interval]
region				
(2 vs 1)	-49.38396	167.1281	-386.6622	287.8942
(3 vs 1)	-9.058983	117.424	-246.0302	227.9123
(4 vs 1)	343.0024	117.6547	105.5656	580.4393

Now we will compute the reference category effects of `region` on the slope of `medage`:

```
. contrast r.region#c.medage
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
region#c.medage			
(2 vs 1)	1	0.16	0.6917
(3 vs 1)	1	0.03	0.8558
(4 vs 1)	1	8.18	0.0066
Joint	3	10.29	0.0000
Residual	42		

	Contrast	Std. Err.	[95% Conf.	Interval]
region#c.medage				
(2 vs 1)	2.208539	5.530981	-8.953432	13.37051
(3 vs 1)	.6928008	3.788735	-6.953175	8.338777
(4 vs 1)	-10.94649	3.827357	-18.67041	-3.22257

At the 5% level, the slope of `medage` for the fourth region differs from that of the first region, but at that level of significance, we cannot say that the slope for the second or third region differs from that of the first.

This model is simple enough that the reference category contrasts reproduce the coefficients for `region` and for the interactions in an equivalent model fit by `regress`.

```
. regress brate region##c.medage
```

Source	SS	df	MS		
Model	37976.3149	7	5425.18784	Number of obs	= 50

_cons	411.8268	108.2084	3.81	0.000	193.4533	630.2002

This will not be the case for models that are more complicated.

Chow tests

Now let's suppose we are fitting a model for birth rates on median age and marriage rate. We are also interested in whether the regression coefficients differ for states in the east versus states in the west. We use census divisions to create a new variable, `west`, that indicates which states are in the western half of the United States.

```
. generate west = inlist(division, 4, 7, 8, 9)
```

We fit a model that includes a separate intercept for `west` as well as an interaction between `west` and each of the other variables in our model.

```
. regress brate i.west##c.medage i.west##c.mrgrate
```

Source	SS	df	MS		
Model	38516.2172	5	7703.24344	Number of obs	= 50
Residual	3680.60281	44	83.6500639	F(5, 44)	= 92.09
				Prob > F	= 0.0000
				R-squared	= 0.9128
				Adj R-squared	= 0.9029
Total	42196.82	49	861.159592	Root MSE	= 9.146

brate	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
1.west	327.8733	58.71793	5.58	0.000	209.5351	446.2115
medage	-7.532304	1.387624	-5.43	0.000	-10.32888	-4.735731
west# c.medage 1	-10.11443	1.849103	-5.47	0.000	-13.84105	-6.387808
mrgrate	828.6813	643.3443	1.29	0.204	-467.8939	2125.257
west# c.mrgrate 1	-800.8036	645.488	-1.24	0.221	-2101.699	500.092
_cons	366.5325	47.08904	7.78	0.000	271.6308	461.4343

We can test the effects of `west` on the intercept and on the slopes of `medage` and `mrgrate`. We will specify all these effects in a single `contrast` command and include the `overall` option to obtain a joint test of effects, that is, a test that the coefficients for eastern states and for western states are equal.

```
. contrast west west#c.medage west#c.mrgrate, overall
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
west	1	31.18	0.0000
west#c.medage	1	29.92	0.0000
west#c.mrgrate	1	1.54	0.2213
Overall	3	22.82	0.0000
Residual	44		

This overall test is referred to as a Chow test in econometrics (Chow 1960).

Beyond linear models

`contrast` may be used after almost any estimation command, with the added benefit that `contrast` provides direct support for testing main and interaction effects that is not available in most estimation commands. To illustrate, we will use `contrast` with results from a logistic regression. Stata's `logit` command fits logistic regression models, reporting the fitted regression coefficients. The `logistic` command fits the same models but reports odds ratios. Although `contrast` can report odds ratios for the computed effects, the tests are all computed from linear combinations of the model coefficients regardless of which estimation command we used.

Suppose we have data on patient satisfaction for three hospitals in a city. Let's begin by fitting a model for `satisfied`, whether the patient was satisfied with his or her treatment, using the main effects of `hospital`:

```
. use http://www.stata-press.com/data/r12/hospital, clear
(Artificial hospital satisfaction data)
. logit satisfied i.hospital
Iteration 0:   log likelihood = -393.72216
Iteration 1:   log likelihood = -387.55736
Iteration 2:   log likelihood =  -387.4768
Iteration 3:   log likelihood = -387.47679
Logistic regression                               Number of obs   =        802
                                                  LR chi2(2)      =      12.49
                                                  Prob > chi2     =     0.0019
Log likelihood = -387.47679                       Pseudo R2       =     0.0159
```

satisfied	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
hospital						
2	.5348129	.2136021	2.50	0.012	.1161604	.9534654
3	.7354519	.2221929	3.31	0.001	.2999618	1.170942
_cons	1.034708	.1391469	7.44	0.000	.7619855	1.307431

Because there are no other independent variables in this model, the reference category effects of `hospital` computed by `contrast` will match the fitted model coefficients, assuming a common reference level.

```
. contrast r.hospital
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	chi2	P>chi2
hospital			
(2 vs 1)	1	6.27	0.0123
(3 vs 1)	1	10.96	0.0009
Joint	2	12.55	0.0019

	Contrast	Std. Err.	[95% Conf.	Interval]
hospital				
(2 vs 1)	.5348129	.2136021	.1161604	.9534654
(3 vs 1)	.7354519	.2221929	.2999618	1.170942

We see that the reference category effects are equal to the fitted coefficients. They also have the same interpretation, the difference in log odds from the reference category. The top table also provides a joint test of these effects, a test of the main effects of `hospital`.

We also have information on the condition for which each patient is being treated in the variable `illness`. Here we fit a logistic regression using a two-way crossed model of `hospital` and `illness`.

```
. label list illness
illness:
           1 heart attack
           2 stroke
           3 pneumonia
           4 lung disease
           5 kidney failure
. logistic satisfied hospital##illness
Logistic regression                               Number of obs   =        802
                                                  LR chi2(14)     =      38.51
                                                  Prob > chi2     =     0.0004
Log likelihood = -374.46865                       Pseudo R2       =     0.0489
```

satisfied	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
hospital

hospital# illness						
2 2	2.434061	1.768427	1.22	0.221	.5860099	10.11016
2 3	4.045805	2.868559	1.97	0.049	1.008058	16.23769
2 4	.54713	.3469342	-0.95	0.342	.1578866	1.89599
2 5	1.594425	1.081104	0.69	0.491	.4221288	6.022312
3 2	.5416535	.3590089	-0.93	0.355	.1477555	1.985635
3 3	1.579502	1.042504	0.69	0.489	.4332209	5.758783
3 4	3.137388	2.595748	1.38	0.167	.6198955	15.87881
3 5	1.672727	1.226149	0.70	0.483	.3976256	7.036812
_cons	2.571429	.8099239	3.00	0.003	1.386983	4.767358

Using `contrast`, we can obtain an ANOVA-style table of tests for the main effects and interaction effects of `hospital` and `illness`.

```
. contrast hospital##illness
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	chi2	P>chi2
hospital	2	14.92	0.0006
illness	4	4.09	0.3937
hospital#illness	8	20.45	0.0088

Our interaction effect is significant, so we decide to evaluate the simple reference category effects of `hospital` within `illness`. We are particularly interested in patient satisfaction when being treated for a heart attack or stroke, so we will use the `i.` operator to limit our output to simple effects within the first two illnesses.

```
. contrast r.hospital@i(1 2).illness, nowald
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	Contrast	Std. Err.	[95% Conf.	Interval]
hospital@illness				
(2 vs 1) 1	.2041611	.4477942	-.6734995	1.081822
(2 vs 1) 2	1.093722	.5721288	-.0276296	2.215074
(3 vs 1) 1	.5371429	.4710983	-.3861928	1.460479
(3 vs 1) 2	-.0759859	.4662325	-.9897847	.8378129

The row labeled `(2 vs 1) 1` estimates simple effects on the log odds when comparing hospital 2 with hospital 1 for patients having heart attacks. These effects are differences in the cell means of the linear predictions.

We can add the `or` option to report an odds ratio for each of these simple effects:

```
. contrast r.hospital@i(1 2).illness, nowald or
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	Odds Ratio	Std. Err.	[95% Conf.	Interval]
hospital@illness				
(2 vs 1) 1	1.226496	.5492177	.509921	2.950049
(2 vs 1) 2	2.985366	1.708014	.9727486	9.162089
(3 vs 1) 1	1.711111	.8061016	.6796395	4.308021
(3 vs 1) 2	.9268293	.4321179	.3716567	2.311306

These odds ratios are just the exponentiated version of the contrasts in the previous table.

For contrasts of the margins of nonlinear predictions, such as predicted probabilities, see [R] **margins, contrast**.

Multiple equations

contrast works with models containing multiple equations. Commands such as intreg and gnbreg allow their ancillary parameters to be modeled as functions of independent variables, and contrast can compute and test effects within these equations. In addition, contrast allows a special pseudofactor for equation—called _eqns—when working with results from manova, mvreg, mlogit, and mprobit.

In example 4 of [MV] **manova**, we fit a two-way MANOVA model using data from Woodard (1931). Here we will fit this model using mvreg. The data represent patients with jaw fractures. y1 is the patient's age, y2 is blood lymphocytes, and y3 is blood polymorphonuclears. Two factor variables, gender and fracture, are used as independent variables.

```
. use http://www.stata-press.com/data/r12/jaw
(Table 4.6 Two-Way Unbalanced Data for Fractures of the Jaw -- Rencher (1998))
. mvreg y1 y2 y3 = gender##fracture, vsquish
```

contrast computes Wald tests using the coefficients from the first equation by default.

```
. contrast gender##fracture
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
y1			
gender	1	2.16	0.1569
fracture	2	2.74	0.0880
gender#fracture	2	1.69	0.2085
Residual	21		

Here we use the `equation()` option to compute the Wald tests in the `y2` equation:

```
. contrast gender##fracture, equation(y2)
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
y2			
gender	1	5.41	0.0301
fracture	2	7.97	0.0027
gender#fracture	2	5.97	0.0088
Residual	21		

Here we use the equation index to compute the Wald tests in the third equation:

```
. contrast gender##fracture, equation(#3)
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
y3			
gender	1	2.23	0.1502
fracture	2	6.36	0.0069
gender#fracture	2	6.66	0.0058
Residual	21		

Here we use the `atequations` option to compute Wald tests for each equation in the model. We also use the `vsquish` option to suppress the extra blank lines between terms.

```
. contrast gender##fracture, atequations vsquish
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
y1			
gender	1	2.16	0.1569
fracture	2	2.74	0.0880
gender#fracture	2	1.69	0.2085
y2			
gender	1	5.41	0.0301
fracture	2	7.97	0.0027
gender#fracture	2	5.97	0.0088
y3			
gender	1	2.23	0.1502
fracture	2	6.36	0.0069
gender#fracture	2	6.66	0.0058
Residual	21		

Because we are investigating the results from `mvreg`, we can use the special `_eqns` factor to test for a marginal effect on the means among the dependent variables:

```
. contrast _eqns
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
_eqns	2	49.19	0.0000
Residual	21		

Here we test whether the main effects of `gender` differ among the dependent variables:

```
. contrast gender#_eqns
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
gender#_eqns	2	3.61	0.0448
Residual	21		

Although it is not terribly interesting in this case, we can even calculate contrasts across equations:

```
. contrast gender#r._eqns
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
gender#_eqns			
(joint) (2 vs 1)	1	5.82	0.0251
(joint) (3 vs 1)	1	0.40	0.5352
Joint	2	3.61	0.0448
Residual	21		

Saved results

`contrast` saves the following in `r()`:

Scalars

`r(df_r)`	variance degrees of freedom, from original estimation results
`r(k_terms)`	number of terms in *termlist*
`r(level)`	confidence level of confidence intervals

Macros

`r(cmd)`	`contrast`
`r(cmdline)`	command as typed
`r(est_cmd)`	`e(cmd)` from original estimation results
`r(est_cmdline)`	`e(cmdline)` from original estimation results
`r(title)`	title in output
`r(overall)`	`overall` or empty
`r(emptycells)`	*empspec* from `emptycells()`
`r(mcmethod)`	*method* from `mcompare()`
`r(mctitle)`	title for *method* from `mcompare()`
`r(mcadjustall)`	`adjustall` or empty
`r(margin_method)`	`asbalanced` or `asobserved`

Matrices

`r(b)`	contrast estimates
`r(V)`	variance–covariance matrix of the contrast estimates
`r(error)`	contrast estimability codes; `0` means estimable, `8` means not estimable
`r(L)`	matrix of contrasts applied to the model coefficients
`r(table)`	matrix containing the contrasts with their standard errors, test statistics, p-values, and confidence intervals
`r(F)`	vector of F statistics; `r(df_r)` present
`r(chi2)`	vector of χ^2 statistics; `r(df_r)` not present
`r(p)`	vector of p-values corresponding to `r(F)` or `r(chi2)`
`r(df)`	vector of degrees of freedom corresponding to `r(p)`
`r(df2)`	vector of denominator degrees of freedom corresponding to `r(F)`

contrast with the post option saves the following in e():

Scalars

e(df_r)	variance degrees of freedom, from original estimation results
e(k_terms)	number of terms in *termlist*

Macros

e(cmd)	contrast
e(cmdline)	command as typed
e(est_cmd)	e(cmd) from original estimation results
e(est_cmdline)	e(cmdline) from original estimation results
e(title)	title in output
e(overall)	overall or empty
e(emptycells)	*empspec* from emptycells()
e(margin_method)	asbalanced or asobserved
e(properties)	b V

Matrices

e(b)	contrast estimates
e(V)	variance–covariance matrix of the contrast estimates
e(error)	contrast estimability codes; 0 means estimable, 8 means not estimable
e(L)	matrix of contrasts applied to the model coefficients
e(F)	vector of F statistics; e(df_r) present
e(chi2)	vector of χ^2 statistics; e(df_r) not present
e(p)	vector of p-values corresponding to e(F) or e(chi2)
e(df)	vector of degrees of freedom corresponding to e(p)
e(df2)	vector of denominator degrees of freedom corresponding to e(F)

Methods and formulas

contrast is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Marginal linear predictions
Contrast operators
Reference level contrasts
Adjacent contrasts
Grand mean contrasts
Helmert contrasts
Reverse Helmert contrasts
Orthogonal polynomial contrasts
Contrasts within interactions
Multiple comparisons

Marginal linear predictions

contrast treats intercept effects separately from slope effects. To illustrate, consider the following parameterization for a quadratic regression of y on x that also models the effects of two factor variables A and B, where the levels of A are indexed by $i = 1, \ldots, k_a$ and the levels of B are indexed by $j = 1, \ldots, k_b$.

$$E(y|A = i, B = j, x) = \eta_{0ij} + \eta_{1ij}x + \eta_{2ij}x^2$$

$$\eta_{0ij} = \eta_0 + \alpha_{0i} + \beta_{0j} + (\alpha\beta)_{0ij}$$

$$\eta_{1ij} = \eta_1 + \alpha_{1i} + \beta_{1j} + (\alpha\beta)_{1ij}$$

$$\eta_{2ij} = \eta_2 + \alpha_{2i} + \beta_{2j} + (\alpha\beta)_{2ij}$$

We have partitioned the coefficients into three groups of parameters: η_{0ij} is a cell prediction for the intercept, η_{1ij} is a cell prediction for the slope on x, and η_{2ij} is a cell prediction for the slope on x^2. For the intercept parameters, η_0 is the intercept, α_{0i} represents a main effect for factor A at its ith level, β_{0j} represents a main effect for factor B at its jth level, and $(\alpha\beta)_{0ij}$ represents an effect for the interaction of A and B at the ijth level. The individual coefficients in η_{1ij} and η_{2ij} have similar interpretations, but the effects are on the slopes of x and x^2, respectively.

The marginal intercepts for A are given by

$$\eta_{0i.} = \sum_{j=1}^{k_b} f_{ij}\eta_{0ij}$$

where f_{ij} is a marginal relative frequency of the jth level of B and is controlled by the `asobserved` and `emptycells(reweight)` options according to

$$f_{ij} = \begin{cases} 1/k_b, & \text{default} \\ w_{.j}/w_{..}, & \texttt{asobserved} \\ 1/(k_b - e_{i.}), & \texttt{emptycells(reweight)} \\ w_{ij}/w_{i.}, & \texttt{emptycells(reweight)} \text{ and } \texttt{asobserved} \end{cases}$$

Above, w_{ij} is the number of individuals with A at its ith level and B at its jth,

$$w_{i.} = \sum_{j=1}^{k_b} w_{ij}$$

$$w_{.j} = \sum_{i=1}^{k_a} w_{ij}$$

$$w_{..} = \sum_{i=1}^{k_a}\sum_{j=1}^{k_b} w_{ij}$$

and $e_{i.}$ is the number of empty cells where A is at its ith level. The marginal intercepts for B and marginal slopes on x and x^2 are similarly defined.

Estimates for the cell intercepts and slopes are computed using the corresponding linear combination of the coefficients from the fitted model. For example, the estimated cell intercepts are computed using

$$\widehat{\eta}_{0ij} = \widehat{\eta}_0 + \widehat{\alpha}_{0i} + \widehat{\beta}_{0j} + \widehat{(\alpha\beta)}_{0ij}$$

and the estimated marginal intercepts for A are computed as

$$\widehat{\eta}_{0i.} = \sum_{j=1}^{k_b} f_{ij}\widehat{\eta}_{0ij}$$

Contrast operators

`contrast` performs Wald tests using linear combinations of marginal linear predictions. For example, the following linear combination can be used to test for a specific effect of factor A on the marginal intercepts.

$$\sum_{i=1}^{k_a} c_i \eta_{0i.}$$

If the c_i elements sum to zero, the linear combination is called a contrast. If the factor A is represented by a variable named `A`, then we specify this contrast using the following syntax:

`{A` c_1 c_2 `...` c_{k_a}`}`

Similarly, the following linear combination can be used to test for a specific interaction effect of factors A and B on the marginal slope of x.

$$\sum_{i=1}^{k_a}\sum_{j=1}^{k_b} c_{ij}\eta_{1ij}$$

If the factor B is represented by a variable named `B`, then we specify this contrast using the following syntax:

`{A#B` c_{11} c_{12} `...` c_{1k_b} c_{21} `...` $c_{k_ak_b}$`}`

`contrast` has variable operators for several commonly used contrasts. Each contrast operator specifies a matrix of linear combinations that yield the requested set of contrasts to be applied to the marginal linear predictions associated with the attached factor variable.

Reference level contrasts

The `r.` operator compares each level with a reference level. Let $\mathbf{R}$ be the corresponding contrast matrix for factor A, and then $\mathbf{R}$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{R}_{ij} = \begin{cases} -1, & \text{if } j \text{ is the reference level} \\ 1, & \text{if } i = j \text{ and } j \text{ is less than the reference level} \\ 1, & \text{if } i + 1 = j \text{ and } j \text{ is greater than the reference level} \\ 0, & \text{otherwise} \end{cases}$$

If $k_a = 5$ and the reference level is the third level of A (specified as `rb(#3).A`), then

$$\mathbf{R} = \begin{pmatrix} 1 & 0 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & -1 & 0 & 1 \end{pmatrix}$$

Adjacent contrasts

The `a.` operator compares each level with the next level. Let $\mathbf{A}$ be the corresponding contrast matrix for factor A, and then $\mathbf{A}$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{A}_{ij} = \begin{cases} 1, & \text{if } i = j \\ -1, & \text{if } i + 1 = j \\ 0, & \text{otherwise} \end{cases}$$

If $k_a = 5$, then

$$\mathbf{A} = \begin{pmatrix} 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 1 & -1 \end{pmatrix}$$

The `ar.` operator compares each level with the previous level. If $\mathbf{A}$ is the contrast matrix for the `a.` operator, then $-\mathbf{A}$ is the corresponding contrast matrix for the `ar.` operator.

Grand mean contrasts

The `g.` operator compares each level with the mean of all the levels. Let $\mathbf{G}$ be the corresponding contrast matrix for factor A, and then $\mathbf{G}$ is a $k_a \times k_a$ matrix with elements

$$\mathbf{G}_{ij} = \begin{cases} 1 - 1/k_a, & \text{if } i = j \\ -1/k_a, & \text{if } i \neq j \end{cases}$$

If $k_a = 5$, then

$$\mathbf{G} = \begin{pmatrix} 4/5 & -1/5 & -1/5 & -1/5 & -1/5 \\ -1/5 & 4/5 & -1/5 & -1/5 & -1/5 \\ -1/5 & -1/5 & 4/5 & -1/5 & -1/5 \\ -1/5 & -1/5 & -1/5 & 4/5 & -1/5 \\ -1/5 & -1/5 & -1/5 & -1/5 & 4/5 \end{pmatrix}$$

The `gw.` operator compares each level with the weighted mean of all the levels. The weights are taken from the observed weighted cell frequencies in the estimation sample of the fitted model. Let $\mathbf{G}_w$ be the corresponding contrast matrix for factor A, and then $\mathbf{G}_w$ is a $k_a \times k_a$ matrix with elements

$$\mathbf{G}_{ij} = \begin{cases} 1 - w_i/w., & \text{if } i = j \\ \quad - w_j/w., & \text{if } i \neq j \end{cases}$$

where w_i is a marginal weight representing the number of individuals with A at its ith level and $w. = \sum_i w_i$.

Helmert contrasts

The `h.` operator compares each level with the mean of the subsequent levels. Let $\mathbf{H}$ be the corresponding contrast matrix for factor A, and then $\mathbf{H}$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{H}_{ij} = \begin{cases} 1, & \text{if } i = j \\ -1/(k_a - i), & \text{if } i < j \\ 0, & \text{otherwise} \end{cases}$$

If $k_a = 5$, then

$$\mathbf{H} = \begin{pmatrix} 1 & -1/4 & -1/4 & -1/4 & -1/4 \\ 0 & 1 & -1/3 & -1/3 & -1/3 \\ 0 & 0 & 1 & -1/2 & -1/2 \\ 0 & 0 & 0 & 1 & -1 \end{pmatrix}$$

The `hw.` operator compares each level with the weighted mean of the subsequent levels. Let $\mathbf{H}_w$ be the corresponding contrast matrix for factor A, and then $\mathbf{H}_w$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{H}_{wij} = \begin{cases} 1, & \text{if } i = j \\ -w_j / \sum_{l=j}^{k_a} w_l, & \text{if } i < j \\ 0, & \text{otherwise} \end{cases}$$

Reverse Helmert contrasts

The `j.` operator compares each level with the mean of the previous levels. Let $\mathbf{J}$ be the corresponding contrast matrix for factor A, and then $\mathbf{J}$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{J}_{ij} = \begin{cases} 1, & \text{if } i + 1 = j \\ -1/i, & \text{if } j \leq i \\ 0, & \text{otherwise} \end{cases}$$

If $k_a = 5$, then

$$\mathbf{H} = \begin{pmatrix} -1 & 1 & 0 & 0 & 0 \\ -1/2 & -1/2 & 1 & 0 & 0 \\ -1/3 & -1/3 & -1/3 & 1 & 0 \\ -1/4 & -1/4 & -1/4 & -1/4 & 1 \end{pmatrix}$$

The `jw.` operator compares each level with the weighted mean of the previous levels. Let $\mathbf{J}_w$ be the corresponding contrast matrix for factor A, and then $\mathbf{J}_w$ is a $(k_a - 1) \times k_a$ matrix with elements

$$\mathbf{J}_{wij} = \begin{cases} 1, & \text{if } i+1 = j \\ -w_j / \sum_{l=1}^{i} w_l, & \text{if } i \leq j \\ 0, & \text{otherwise} \end{cases}$$

Orthogonal polynomial contrasts

The `p.` operator applies orthogonal polynomial contrasts using the level values of the attached factor variable. The `q.` operator applies orthogonal polynomial contrasts using the level indices of the attached factor variable. These two operators are equivalent when the level values of the attached factor are equally spaced. The `pw.` and `qw.` operators are weighted versions of `p.` and `q.`, where the weights are taken from the observed weighted cell frequencies in the estimation sample of the fitted model. `contrast` uses the Christoffel–Darboux recurrence formula for computing orthogonal polynomial contrasts (Abramowitz and Stegun 1972). The elements of the contrasts are normalized such that

$$\mathbf{Q}'\mathbf{W}\mathbf{Q} = \frac{1}{w_.}\mathbf{I}$$

where $\mathbf{W}$ is a diagonal matrix of the marginal cell weights $w_1, w_2, \ldots, w_k$ of the attached factor variable (all 1 for `p.` and `q.`), and $w_.$ is the sum of the weights (the number of levels k for `p.` and `q.`).

Contrasts within interactions

Contrast operators are allowed to be specified on factor variables participating in interactions. In such cases, `contrast` applies the proper matrix product of the contrast matrices to the cell margins of the interacted factor variables.

For example, consider the contrasts implied by specifying `r.A#h.B`. Let $\mathbf{M}$ be the matrix of estimated cell margins for the levels of A and B, where the rows of $\mathbf{M}$ are indexed by the levels of A and the columns are indexed by the levels of B. `contrast` puts the estimated cell margins in the following vector form:

$$\mathbf{v} = \text{vec}(\mathbf{M}') = \begin{pmatrix} \mathbf{M}_{11} \\ \mathbf{M}_{12} \\ \vdots \\ \mathbf{M}_{1k_b} \\ \mathbf{M}_{21} \\ \mathbf{M}_{22} \\ \vdots \\ \mathbf{M}_{2k_b} \\ \vdots \\ \mathbf{M}_{k_a k_b} \end{pmatrix}$$

The individual contrasts are then given by the elements of

$$(\mathbf{R} \otimes \mathbf{H})\mathbf{v}$$

where $\otimes$ denotes the Kronecker direct product.

Multiple comparisons

See [R] **pwcompare** for details on the methods and formulas used to adjust p-values and confidence intervals for multiple comparisons. The formulas for Bonferroni's method and Šidák's method are presented with $m = k(k-1)/2$, the number of pairwise comparisons for a factor term with k levels. For contrasts, m is instead the number of contrasts being performed on the factor term; often, $m = k - 1$ for a term with k levels.

Title

contrast postestimation — Postestimation tools for contrast

Description

The following postestimation commands are available after `contrast, post`:

Command	Description
`estat`	VCE; `estat vce` only
`estat` (svy)	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Remarks

In *Orthogonal polynomial contrasts* in [R] **contrast**, we used the `p.` operator to test the orthogonal polynomial effects of age group.

```
. contrast p.agegrp, noeffects
```

We then used a second `contrast` command,

```
. contrast p(2 3 4).agegrp, noeffects
```

selecting levels to test whether the quadratic, cubic, and quartic contrasts were jointly significant.

We can perform the same joint test by using the `test` command after specifying the `post` option with our first `contrast` command.

```
. use http://www.stata-press.com/data/r12/cholesterol
(Artificial cholesterol data)
. anova chol agegrp
  (output omitted)
. contrast p.agegrp, noeffects post
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
agegrp			
(linear)	1	139.11	0.0000
(quadratic)	1	0.15	0.6962
(cubic)	1	0.37	0.5448
(quartic)	1	0.43	0.5153
Joint	4	35.02	0.0000
Residual	70		

```
. test p2.agegrp p3.agegrp p4.agegrp
 ( 1)  p2.agegrp = 0
 ( 2)  p3.agegrp = 0
 ( 3)  p4.agegrp = 0
       F(  3,    70) =    0.32
            Prob > F =    0.8129
```

Title

copyright — Display copyright information

Syntax

```
copyright
```

Description

`copyright` presents copyright notifications concerning tools, libraries, etc., used in the construction of Stata.

Remarks

The correct form for a copyright notice is

Copyright *dates* by *author/owner*

The word "Copyright" is spelled out. You can use the © symbol, but "(C)" has never been given legal recognition. The phrase "All Rights Reserved" was historically required but is no longer needed.

Currently, most works are copyrighted from the moment they are written, and no copyright notice is required. Copyright concerns the protection of the expression and structure of facts and ideas, not the facts and ideas themselves. Copyright concerns the ownership of the expression and not the name given to the expression, which is covered under trademark law.

Copyright law as it exists today began in England in 1710 with the Statute of Anne, *An Act for the Encouragement of Learning, by Vesting the Copies of Printed Books in the Authors or Purchases of Such Copies, during the Times therein mentioned*. In 1672, Massachusetts introduced the first copyright law in what was to become the United States. After the Revolutionary War, copyright was introduced into the U.S. Constitution in 1787 and went into effect on May 31, 1790. On June 9, 1790, the first copyright in the United States was registered for *The Philadelphia Spelling Book* by John Barry.

There are significant differences in the understanding of copyright in the English- and non–English-speaking world. The Napoleonic or Civil Code, the dominant legal system in the non–English-speaking world, splits the rights into two classes: the author's economic rights and the author's moral rights. Moral rights are available only to "natural persons". Legal persons (corporations) have economic rights but not moral rights.

copyright freetype — FreeType copyright notification

Description

Stata uses portions of FreeType, a library used by JagPDF, which helps create PDF files, with the express permission of the authors.

StataCorp thanks and acknowledges the authors of FreeType for producing FreeType and allowing its use in Stata and other software.

For more information about FreeType, visit http://www.freetype.org/.

The full FreeType copyright notice is

Legal Terms

0. Definitions

Throughout this license, the terms 'package', 'FreeType Project', and 'FreeType archive' refer to the set of files originally distributed by the authors (David Turner, Robert Wilhelm, and Werner Lemberg) as the 'FreeType Project', be they named as alpha, beta or final release.

'You' refers to the licensee, or person using the project, where 'using' is a generic term including compiling the project's source code as well as linking it to form a 'program' or 'executable'. This program is referred to as 'a program using the FreeType engine'.

This license applies to all files distributed in the original FreeType Project, including all source code, binaries and documentation, unless otherwise stated in the file in its original, unmodified form as distributed in the original archive. If you are unsure whether or not a particular file is covered by this license, you must contact us to verify this.

This license applies to all files distributed in the original FreeType Project, including all source code, binaries and documentation, unless otherwise stated in the file in its original, unmodified form as distributed in the original archive. If you are unsure whether or not a particular file is covered by this license, you must contact us to verify this.

1. No Warranty

THE FREETYPE PROJECT IS PROVIDED 'AS IS' WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT WILL ANY OF THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY DAMAGES CAUSED BY THE USE OR THE INABILITY TO USE, OF THE FREETYPE PROJECT.

2. Redistribution

This license grants a worldwide, royalty-free, perpetual and irrevocable right and license to use, execute, perform, compile, display, copy, create derivative works of, distribute and sublicense the FreeType Project (in both source and object code forms) and derivative works thereof for any purpose; and to authorize others to exercise some or all of the rights granted herein, subject to the following conditions:

- Redistribution of source code must retain this license file (‘FTL.TXT’) unaltered; any additions, deletions or changes to the original files must be clearly indicated in accompanying documentation. The copyright notices of the unaltered, original files must be preserved in all copies of source files.
- Redistribution in binary form must provide a disclaimer that states that the software is based in part of the work of the FreeType Team, in the distribution documentation. We also encourage you to put an URL to the FreeType web page in your documentation, though this isn’t mandatory.

These conditions apply to any software derived from or based on the FreeType Project, not just the unmodified files. If you use our work, you must acknowledge us. However, no fee need be paid to us.

3. Advertising

Neither the FreeType authors and contributors nor you shall use the name of the other for commercial, advertising, or promotional purposes without specific prior written permission.

We suggest, but do not require, that you use one or more of the following phrases to refer to this software in your documentation or advertising materials: ‘FreeType Project’, ‘FreeType Engine’, ‘FreeType library’, or ‘FreeType Distribution’.

As you have not signed this license, you are not required to accept it. However, as the FreeType Project is copyrighted material, only this license, or another one contracted with the authors, grants you the right to use, distribute, and modify it. Therefore, by using, distributing, or modifying the FreeType Project, you indicate that you understand and accept all the terms of this license.

4. Contacts

There are two mailing lists related to FreeType:

- freetype@nongnu.org

  Discusses general use and applications of FreeType, as well as future and wanted additions to the library and distribution. If you are looking for support, start in this list if you haven’t found anything to help you in the documentation.

- freetype-devel@nongnu.org

  Discusses bugs, as well as engine internals, design issues, specific licenses, porting, etc.

Title

correlate — Correlations (covariances) of variables or coefficients

Syntax

Display correlation matrix or covariance matrix

`correlate` [*varlist*] [*if*] [*in*] [*weight*] [, *correlate_options*]

Display all pairwise correlation coefficients

`pwcorr` [*varlist*] [*if*] [*in*] [*weight*] [, *pwcorr_options*]

correlate_options	Description
Options	
`means`	display means, standard deviations, minimums, and maximums with matrix
`noformat`	ignore display format associated with variables
`covariance`	display covariances
`wrap`	allow wide matrices to wrap

pwcorr_options	Description
Main	
`obs`	print number of observations for each entry
`sig`	print significance level for each entry
`listwise`	use listwise deletion to handle missing values
`casewise`	synonym for `listwise`
`print(#)`	significance level for displaying coefficients
`star(#)`	significance level for displaying with a star
`bonferroni`	use Bonferroni-adjusted significance level
`sidak`	use Šidák-adjusted significance level

varlist may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`by` is allowed with `correlate` and `pwcorr`; see [D] **by**.
`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

Menu

correlate

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Correlations and covariances

pwcorr

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Pairwise correlations

Description

The `correlate` command displays the correlation matrix or covariance matrix for a group of variables. If *varlist* is not specified, the matrix is displayed for all variables in the dataset. Also see the `estat vce` command in [R] **estat**.

`pwcorr` displays all the pairwise correlation coefficients between the variables in *varlist* or, if *varlist* is not specified, all the variables in the dataset.

Options for correlate

Options

`means` displays summary statistics (means, standard deviations, minimums, and maximums) with the matrix.

`noformat` displays the summary statistics requested by the `means` option in `g` format, regardless of the display formats associated with the variables.

`covariance` displays the covariances rather than the correlation coefficients.

`wrap` requests that no action be taken on wide correlation matrices to make them readable. It prevents Stata from breaking wide matrices into pieces to enhance readability. You might want to specify this option if you are displaying results in a window wider than 80 characters. Then you may need to `set linesize` to however many characters you can display across a line; see [R] **log**.

Options for pwcorr

Main

`obs` adds a line to each row of the matrix reporting the number of observations used to calculate the correlation coefficient.

`sig` adds a line to each row of the matrix reporting the significance level of each correlation coefficient.

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the estimation sample if any of the variables in *varlist* is missing for that observation. By default, `pwcorr` handles missing values by pairwise deletion; all available observations are used to calculate each pairwise correlation without regard to whether variables outside that pair are missing.

`correlate` uses listwise deletion. Thus `listwise` allows users of `pwcorr` to mimic `correlate`'s treatment of missing values while retaining access to `pwcorr`'s features.

`casewise` is a synonym for `listwise`.

`print(#)` specifies the significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing `pwcorr, print(.10)` would list only correlation coefficients significant at the 10% level or better.

`star(#)` specifies the significance level of correlation coefficients to be starred. Typing `pwcorr, star(.05)` would star all correlation coefficients significant at the 5% level or better.

`bonferroni` makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus `pwcorr, print(.05) bonferroni` prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

`sidak` makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus `pwcorr, print(.05) sidak` prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

Remarks

Remarks are presented under the following headings:

correlate
pwcorr

correlate

Typing `correlate` by itself produces a correlation matrix for all variables in the dataset. If you specify the *varlist*, a correlation matrix for just those variables is displayed.

▷ Example 1

We have state data on demographic characteristics of the population. To obtain a correlation matrix, we type

```
. use http://www.stata-press.com/data/r12/census13
(1980 Census data by state)
. correlate
(obs=50)
```

	state	brate	pop	medage	division	region	mrgrate
state	1.0000						
brate	0.0208	1.0000					
pop	-0.0540	-0.2830	1.0000				
medage	-0.0624	-0.8800	0.3294	1.0000			
division	-0.1345	0.6356	-0.1081	-0.5207	1.0000		
region	-0.1339	0.6086	-0.1515	-0.5292	0.9688	1.0000	
mrgrate	0.0509	0.0677	-0.1502	-0.0177	0.2280	0.2490	1.0000
dvcrate	-0.0655	0.3508	-0.2064	-0.2229	0.5522	0.5682	0.7700
medagesq	-0.0621	-0.8609	0.3324	0.9984	-0.5162	-0.5239	-0.0202

	dvcrate	medagesq
dvcrate	1.0000	
medagesq	-0.2192	1.0000

Because we did not specify the `wrap` option, Stata did its best to make the result readable by breaking the table into two parts.

To obtain the correlations between mrgrate, dvcrate, and medage, we type

```
. correlate mrgrate dvcrate medage
(obs=50)
             | mrgrate  dvcrate   medage
-------------+---------------------------
    mrgrate  |  1.0000
    dvcrate  |  0.7700   1.0000
     medage  | -0.0177  -0.2229   1.0000
```

◁

▷ Example 2

The pop variable in our previous example represents the total population of the state. Thus, to obtain population-weighted correlations among mrgrate, dvcrate, and medage, we type

```
. correlate mrgrate dvcrate medage [w=pop]
(analytic weights assumed)
(sum of wgt is   2.2591e+08)
(obs=50)
             | mrgrate  dvcrate   medage
-------------+---------------------------
    mrgrate  |  1.0000
    dvcrate  |  0.5854   1.0000
     medage  | -0.1316  -0.2833   1.0000
```

◁

With the covariance option, correlate can be used to obtain covariance matrices, as well as correlation matrices, for both weighted and unweighted data.

▷ Example 3

To obtain the matrix of covariances between mrgrate, dvcrate, and medage, we type correlate mrgrate dvcrate medage, covariance:

```
. correlate mrgrate dvcrate medage, covariance
(obs=50)
             | mrgrate  dvcrate   medage
-------------+---------------------------
    mrgrate  |  .000662
    dvcrate  |  .000063  1.0e-05
     medage  | -.000769 -.001191  2.86775
```

We could have obtained the pop-weighted covariance matrix by typing correlate mrgrate dvcrate medage [w=pop], covariance.

◁

pwcorr

correlate calculates correlation coefficients by using casewise deletion; when you request correlations of variables x_1, x_2, ..., x_k, any observation for which any of x_1, x_2, ..., x_k is missing is not used. Thus if x_3 and x_4 have no missing values, but x_2 is missing for half the data, the correlation between x_3 and x_4 is calculated using only the half of the data for which x_2 is not missing. Of course, you can obtain the correlation between x_3 and x_4 by using all the data by typing correlate x_3 x_4.

pwcorr makes obtaining such pairwise correlation coefficients easier.

▷ Example 4

Using `auto.dta`, we investigate the correlation between several of the variables.

```
. use http://www.stata-press.com/data/r12/auto1
(Automobile Models)
. pwcorr mpg price rep78 foreign, obs sig
```

	mpg	price	rep78	foreign
mpg	1.0000			
	74			
price	-0.4594	1.0000		
	0.0000			
	74	74		
rep78	0.3739	0.0066	1.0000	
	0.0016	0.9574		
	69	69	69	
foreign	0.3613	0.0487	0.5922	1.0000
	0.0016	0.6802	0.0000	
	74	74	69	74

```
. pwcorr mpg price headroom rear_seat trunk rep78 foreign, print(.05) star(.01)
```

	mpg	price	headroom	rear_s~t	trunk	rep78	foreign
mpg	1.0000						
price	-0.4594*	1.0000					
headroom	-0.4220*		1.0000				
rear_seat	-0.5213*	0.4194*	0.5238*	1.0000			
trunk	-0.5703*	0.3143*	0.6620*	0.6480*	1.0000		
rep78	0.3739*					1.0000	
foreign	0.3613*		-0.2939	-0.2409	-0.3594*	0.5922*	1.0000

```
. pwcorr mpg price headroom rear_seat trunk rep78 foreign, print(.05) bon
```

	mpg	price	headroom	rear_s~t	trunk	rep78	foreign
mpg	1.0000						
price	-0.4594	1.0000					
headroom	-0.4220		1.0000				
rear_seat	-0.5213	0.4194	0.5238	1.0000			
trunk	-0.5703		0.6620	0.6480	1.0000		
rep78	0.3739					1.0000	
foreign	0.3613				-0.3594	0.5922	1.0000

◁

❑ Technical note

The `correlate` command will report the correlation matrix of the data, but there are occasions when you need the matrix stored as a Stata matrix so that you can further manipulate it. You can obtain the matrix by typing

```
. matrix accum R = varlist, nocons dev
. matrix R = corr(R)
```

The first line places the cross-product matrix of the data in matrix `R`. The second line converts that to a correlation matrix. Also see [P] **matrix define** and [P] **matrix accum**.

❑

Saved results

correlate saves the following in r():

Scalars

r(N)	number of observations
r(rho)	ρ (first and second variables)
r(cov_12)	covariance (covariance only)
r(Var_1)	variance of first variable (covariance only)
r(Var_2)	variance of second variable (covariance only)

Matrices

r(C)	correlation or covariance matrix

pwcorr will leave in its wake only the results of the last call that it makes internally to correlate for the correlation between the last variable and itself. Only rarely is this feature useful.

Methods and formulas

pwcorr is implemented as an ado-file.

For a discussion of correlation, see, for instance, Snedecor and Cochran (1989, 177–195); for an introductory explanation using Stata examples, see Acock (2010, 186–192).

According to Snedecor and Cochran (1989, 180), the term "co-relation" was first proposed by Galton (1888). The product-moment correlation coefficient is often called the Pearson product-moment correlation coefficient because Pearson (1896) and Pearson and Filon (1898) were partially responsible for popularizing its use. See Stigler (1986) for information on the history of correlation.

The estimate of the product-moment correlation coefficient, ρ, is

$$\widehat{\rho} = \frac{\sum_{i=1}^{n} w_i(x_i - \overline{x})(y_i - \overline{y})}{\sqrt{\sum_{i=1}^{n} w_i(x_i - \overline{x})^2}\sqrt{\sum_{i=1}^{n} w_i(y_i - \overline{y})^2}}$$

where w_i are the weights, if specified, or $w_i = 1$ if weights are not specified. $\overline{x} = (\sum w_i x_i)/(\sum w_i)$ is the mean of x, and $\overline{y}$ is similarly defined.

The unadjusted significance level is calculated by pwcorr as

$$p = 2 * \texttt{ttail}(n-2, |\widehat{\rho}|\sqrt{n-2}/\sqrt{1-\widehat{\rho}^2})$$

Let v be the number of variables specified so that $k = v(v-1)/2$ correlation coefficients are to be estimated. If bonferroni is specified, the adjusted significance level is $p' = \min(1, kp)$. If sidak is specified, $p' = \min\{1, 1-(1-p)^k\}$. In both cases, see *Methods and formulas* in [R] **oneway** for a more complete description of the logic behind these adjustments.

Carlo Emilio Bonferroni (1892–1960) studied in Turin and taught there and in Bari and Florence. He published on actuarial mathematics, probability, statistics, analysis, geometry, and mechanics. His work on probability inequalities has been applied to simultaneous statistical inference, although the method known as Bonferroni adjustment usually relies only on an inequality established earlier by Boole.

Karl Pearson (1857–1936) studied mathematics at Cambridge. He was professor of applied mathematics (1884–1911) and eugenics (1911–1933) at University College London. His publications include literary, historical, philosophical, and religious topics. Statistics became his main interest in the early 1890s after he learned about its application to biological problems. His work centered on distribution theory, the method of moments, correlation, and regression. Pearson introduced the chi-squared test and the terms coefficient of variation, contingency table, heteroskedastic, histogram, homoskedastic, kurtosis, mode, random sampling, random walk, skewness, standard deviation, and truncation. Despite many strong qualities, he also fell into prolonged disagreements with others, most notably, William Bateson and R. A. Fisher.

Zbyněk Šidák (1933–1999) was a notable Czech statistician and probabilist. He worked on Markov chains, rank tests, multivariate distribution theory and multiple-comparison methods, and he served as the chief editor of *Applications of Mathematics*.

Title

cumul — Cumulative distribution

Syntax

`cumul` *varname* [*if*] [*in*] [*weight*] , `generate(`*newvar*`)` [*options*]

options	Description
Main	
* `generate(`*newvar*`)`	create variable *newvar*
`freq`	use frequency units for cumulative
`equal`	generate equal cumulatives for tied values

* `generate(`*newvar*`)` is required.

`by` is allowed; see [D] **by**.

`fweights` and `aweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Generate cumulative distribution

Description

`cumul` creates *newvar*, defined as the empirical cumulative distribution function of *varname*.

Options

Main

`generate(`*newvar*`)` is required. It specifies the name of the new variable to be created.

`freq` specifies that the cumulative be in frequency units; otherwise, it is normalized so that *newvar* is 1 for the largest value of *varname*.

`equal` requests that observations with equal values in *varname* get the same cumulative value in *newvar*.

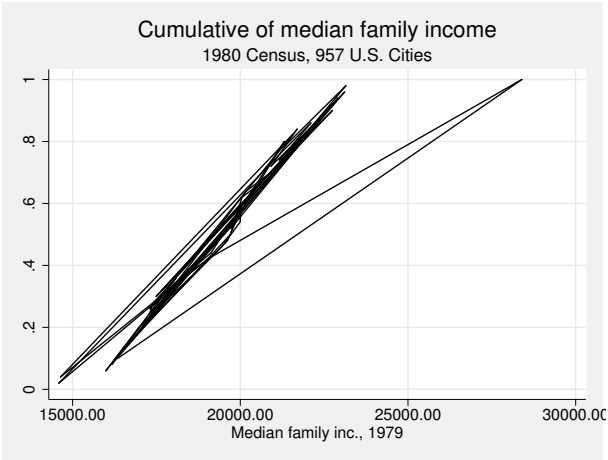
Jean Baptiste Joseph Fourier (1768–1830) was born in Auxerre in France. As a young man, Fourier became entangled in the complications of the French Revolution. As a result, he was arrested and put into prison, where he feared he might meet his end at the guillotine. When he was not in prison, he was studying, researching, and teaching mathematics. Later, he served Napolean's army in Egypt as a scientific adviser. Upon his return to France in 1801, he was appointed Prefect of the Department of Isère. While prefect, Fourier worked on the mathematical basis of the theory of heat, which is based on what are now called Fourier series. This work was published in 1822, despite the skepticism of Lagrange, Laplace, Legendre, and others—who found the work lacking in generality and even rigor—and disagreements of both priority and substance with Biot and Poisson.

Remarks

Example 1

`cumul` is most often used with `graph` to graph the empirical cumulative distribution. For instance, we have data on the median family income of 957 U.S. cities:

```
. use http://www.stata-press.com/data/r12/hsng
(1980 Census housing data)
. cumul faminc, gen(cum)
. sort cum
. line cum faminc, ylab(, grid) ytitle("") xlab(, grid)
> title("Cumulative of median family income")
> subtitle("1980 Census, 957 U.S. Cities")
```



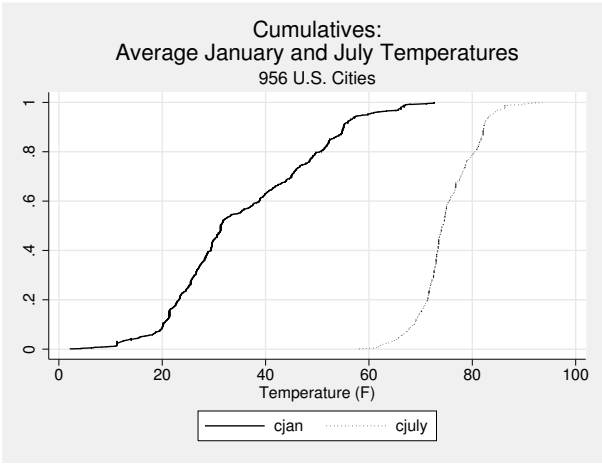
It would have been enough to type `line cum faminc`, but we wanted to make the graph look better; see [G-2] **graph twoway line**.

If we had wanted a weighted cumulative, we would have typed `cumul faminc [w=pop]` at the first step. ◁

Example 2

To graph two (or more) cumulatives on the same graph, use `cumul` and `stack`; see [D] **stack**. For instance, we have data on the average January and July temperatures of 956 U.S. cities:

```
. use http://www.stata-press.com/data/r12/citytemp, clear
(City Temperature Data)
. cumul tempjan, gen(cjan)
. cumul tempjuly, gen(cjuly)
. stack  cjan tempjan  cjuly tempjuly, into(c temp) wide clear
. line cjan cjuly temp, sort ylab(, grid) ytitle("") xlab(, grid)
> xtitle("Temperature (F)")
> title("Cumulatives:" "Average January and July Temperatures")
> subtitle("956 U.S. Cities") clstyle(. dot)
```



As before, it would have been enough to type `line cjan cjuly temp, sort`. See [D] **stack** for an explanation of how the `stack` command works.

◁

❑ Technical note

According to Beniger and Robyn (1978), Fourier (1821) published the first graph of a cumulative frequency distribution, which was later given the name "ogive" by Galton (1875).

❑

Methods and formulas

`cumul` is implemented as an ado-file.

Acknowledgment

The `equal` option was added by Nicholas J. Cox, Durham University, Durham, UK.

Title

cusum — Graph cumulative spectral distribution

Syntax

`cusum` *yvar xvar* [*if*] [*in*] [, *options*]

options	Description
Main	
`generate(`*newvar*`)`	save cumulative sum in *newvar*
`yfit(`*fitvar*`)`	calculate cumulative sum against *fitvar*
`nograph`	suppress the plot
`nocalc`	suppress cusum test statistics
Cusum plot	
connect_options	affect the rendition of the plotted line
Add plots	
`addplot(`*plot*`)`	add plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Other > Quality control > Cusum plots and tests for binary variables

Description

`cusum` graphs the cumulative sum (cusum) of a binary (0/1) variable, *yvar*, against a (usually) continuous variable, *xvar*.

Options

Main

`generate(`*newvar*`)` saves the cusum in *newvar*.

`yfit(`*fitvar*`)` calculates a cusum against *fitvar*, that is, the running sums of the "residuals" *fitvar* minus *yvar*. Typically, *fitvar* is the predicted probability of a positive outcome obtained from a logistic regression analysis.

`nograph` suppresses the plot.

`nocalc` suppresses calculation of the cusum test statistics.

Cusum plot

connect_options affect the rendition of the plotted line; see [G-3] ***connect_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

The cusum is the running sum of the proportion of ones in the sample, a constant number, minus *yvar*,

$$c_j = \sum_{k=1}^{j} f - yvar_{(k)}, \qquad 1 \le j \le N$$

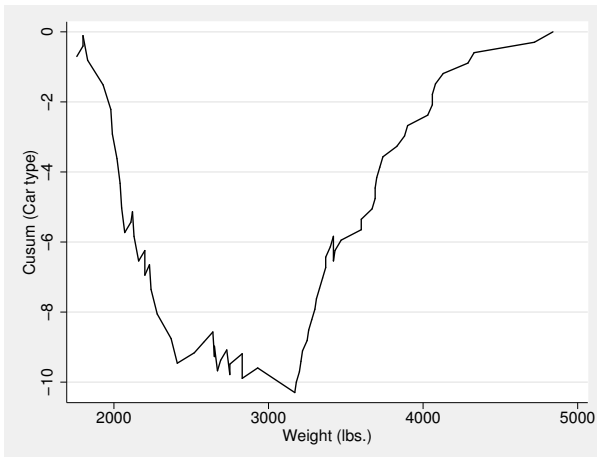
where $f = (\sum yvar)/N$ and $yvar_{(k)}$ refers to the corresponding value of *yvar* when *xvar* is placed in ascending order: $xvar_{(k+1)} \ge xvar_{(k)}$. Tied values of *xvar* are broken at random. If you want them broken the same way in two runs, you must set the random-number seed to the same value before giving the `cusum` command; see [R] **set seed**.

A U-shaped or inverted U-shaped cusum indicates, respectively, a negative or a positive trend of *yvar* with *xvar*. A sinusoidal shape is evidence of a nonmonotonic (for example, quadratic) trend. `cusum` displays the maximum absolute cusum for monotonic and nonmonotonic trends of *yvar* on *xvar*. These are nonparametric tests of departure from randomness of *yvar* with respect to *xvar*. Approximate values for the tests are given.

▷ Example 1

For the automobile dataset, `auto.dta`, we wish to investigate the relationship between `foreign` (0 = domestic, 1 = foreign) and car weight as follows:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. cusum foreign weight
```

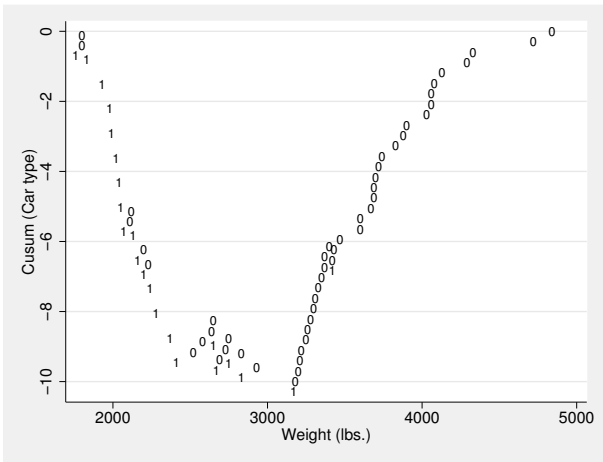


Variable	Obs	Pr(1)	CusumL	zL	Pr>zL	CusumQ	zQ	Pr>zQ
foreign	74	0.2973	10.30	3.963	0.000	3.32	0.469	0.320

The resulting plot, which is U-shaped, suggests a negative monotonic relationship. The trend is confirmed by a highly significant linear cusum statistic, labeled `CusumL` in the output above.

Some 29.73% of the cars are foreign (coded 1). The proportion of foreign cars diminishes with increasing weight. The domestic cars are crudely heavier than the foreign ones. We could have discovered that by typing `table foreign, stats(mean weight)`, but such an approach does not give the full picture of the relationship. The quadratic cusum (`CusumQ`) is not significant, so we do not suspect any tendency for the very heavy cars to be foreign rather than domestic. A slightly enhanced version of the plot shows the preponderance of domestic (coded 0) cars at the heavy end of the weight axis:

```
. label values foreign
. cusum foreign weight, s(none) recast(scatter) mlabel(foreign) mlabp(0)
```



Variable	Obs	Pr(1)	CusumL	zL	Pr>zL	CusumQ	zQ	Pr>zQ
foreign	74	0.2973	10.30	3.963	0.000	2.92	0.064	0.475

The example is, of course, artificial, because we would not really try to model the probability of a car being foreign given its weight.

◁

Saved results

`cusum` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(P_zl)`	p-value for test (linear)
`r(prop1)`	proportion of positive outcomes	`r(cusumq)`	quadratic cusum
`r(cusuml)`	cusum	`r(zq)`	test (quadratic)
`r(zl)`	test (linear)	`r(P_zq)`	p-value for test (quadratic)

Methods and formulas

`cusum` is implemented as an ado-file.

Acknowledgment

`cusum` was written by Patrick Royston, MRC Clinical Trials Unit, London.

Title

db — Launch dialog

Syntax

Syntax for db

`db` *commandname*

For programmers

`db` *commandname* [`, message(`*string*`) debug dryrun`]

Set system parameter

`set maxdb #` [`, permanently`]

where # must be between 5 and 1,000.

Description

`db` is the command-line way to launch a dialog for a Stata command.

The second syntax (which is the same but includes options) is for use by programmers.

If you wish to allow the launching of dialogs from a help file, see [P] **smcl** for information on the `dialog` SMCL directive.

`set maxdb` sets the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session. The default value of `maxdb` is 50.

Options

`message(`*string*`)` specifies that *string* be passed to the dialog box, where it can be referred to from the `__MESSAGE STRING` property.

`debug` specifies that the underlying dialog box be loaded with debug messaging turned on.

`dryrun` specifies that, rather than launching the dialog, `db` show the commands it would issue to launch the dialog.

`permanently` specifies that, in addition to making the change right now, the `maxdb` setting be remembered and become the default setting when you invoke Stata.

Remarks

The usual way to launch a dialog is to open the **Data**, **Graphics**, or **Statistics** menu and to make your selection from there. When you know the name of the command that you want to run, however, `db` provides a way to invoke the dialog from the command line.

`db` follows the same abbreviation rules that Stata's command-line interface follows. So, to launch the dialog for `regress`, you can type

```
. db regress
```

or

```
. db reg
```

Say that you use the dialog box for `regress`, either by selecting

Statistics > Linear models and related > Linear regression

or by typing

```
. db regress
```

You fit a regression.

Much later during the session, you return to the `regress` dialog box. It will have the contents as you left them if 1) you have not typed `clear all` between the first and second invocations; 2) you have not typed `discard` between the two invocations; and 3) you have not used more than 50 different dialog boxes—regardless of how many times you have used each—between the first and second invocations of `regress`. If you use 51 or more, the contents of the `regress` dialog box will be forgotten.

`set maxdb` determines how many different dialog boxes are remembered. A dialog box takes, on average, about 20 KB of memory, so the 50 default corresponds to allowing dialog boxes to consume about 1 MB of memory.

Methods and formulas

`db` is implemented as an ado-file.

Description

`symplot` graphs a symmetry plot of *varname*.

`quantile` plots the ordered values of *varname* against the quantiles of a uniform distribution.

`qqplot` plots the quantiles of $varname_1$ against the quantiles of $varname_2$ (Q−Q plot).

`qnorm` plots the quantiles of *varname* against the quantiles of the normal distribution (Q−Q plot).

`pnorm` graphs a standardized normal probability plot (P−P plot).

`qchi` plots the quantiles of *varname* against the quantiles of a χ^2 distribution (Q−Q plot).

`pchi` graphs a χ^2 probability plot (P−P plot).

See [R] **regress postestimation** for regression diagnostic plots and [R] **logistic postestimation** for logistic regression diagnostic plots.

Options for symplot, quantile, and qqplot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affect the rendition of the reference line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Options for qnorm and pnorm

Main

`grid` adds grid lines at the 0.05, 0.10, 0.25, 0.50, 0.75, 0.90, and 0.95 quantiles when specified with `qnorm`. With `pnorm`, `grid` is equivalent to `yline(.25,.5,.75) xline(.25,.5,.75)`.

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affect the rendition of the reference line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Options for qchi and pchi

Main

`grid` adds grid lines at the 0.05, 0.10, 0.25, 0.50, 0.75, 0.90, and .95 quantiles when specified with `qchi`. With `pchi`, `grid` is equivalent to `yline(.25,.5,.75) xline(.25,.5,.75)`.

`df(#)` specifies the degrees of freedom of the χ^2 distribution. The default is `df(1)`.

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affect the rendition of the reference line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Remarks are presented under the following headings:

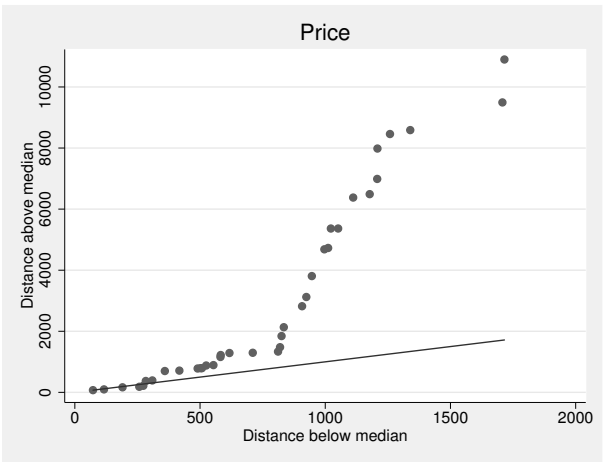
symplot
quantile
qqplot
qnorm
pnorm
qchi
pchi

symplot

▷ Example 1

We have data on 74 automobiles. To make a symmetry plot of the variable `price`, we type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. symplot price
```



All points would lie along the reference line (defined as $y = x$) if car prices were symmetrically distributed. The points in this plot lie above the reference line, indicating that the distribution of car prices is skewed to the right—the most expensive cars are far more expensive than the least expensive cars are inexpensive.

The logic works as follows: a variable, z, is distributed symmetrically if

$$\text{median} - z_{(i)} = z_{(N+1-i)} - \text{median}$$

where $z_{(i)}$ indicates the ith-order statistic of z. `symplot` graphs $y_i = \text{median} - z_{(i)}$ versus $x_i = z_{(N+1-i)} - \text{median}$.

For instance, consider the largest and smallest values of `price` in the example above. The most expensive car costs \$15,906 and the least expensive, \$3,291. Let's compare these two cars with the typical car in the data and see how much more it costs to buy the most expensive car, and compare that with how much less it costs to buy the least expensive car. If the automobile price distribution is symmetric, the price differences would be the same.

Before we can make this comparison, we must agree on a definition for the word "typical". Let's agree that "typical" means median. The price of the median car is \$5,006.50, so the most expensive car costs \$10,899.50 more than the median car, and the least expensive car costs \$1,715.50 less than the median car. We now have one piece of evidence that the car price distribution is not symmetric. We can repeat the experiment for the second-most-expensive car and the second-least-expensive car. We find that the second-most-expensive car costs \$9,494.50 more than the median car, and the second-least-expensive car costs \$1,707.50 less than the median car. We now have more evidence. We can continue doing this with the third most expensive and the third least expensive, and so on.

Once we have all these numbers, we want to compare each pair and ask how similar, on average, they are. The easiest way to do that is to plot all the pairs.

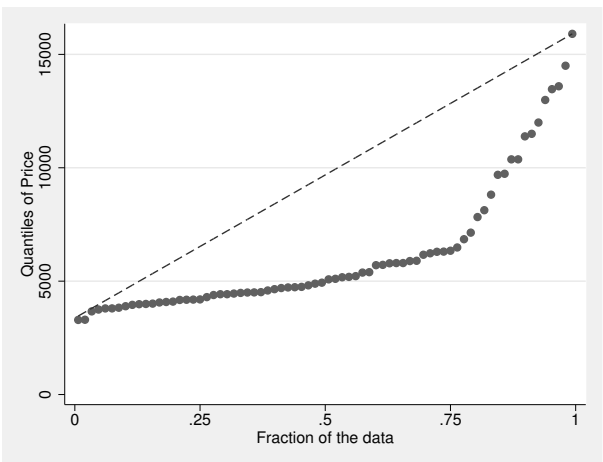
◁

quantile

▷ Example 2

We have data on the prices of 74 automobiles. To make a quantile plot of `price`, we type

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. quantile price, rlopts(clpattern(dash))
```



We changed the pattern of the reference line by specifying `rlopts(clpattern(dash))`.

In a quantile plot, each value of the variable is plotted against the fraction of the data that have values less than that fraction. The diagonal line is a reference line. If automobile prices were rectangularly distributed, all the data would be plotted along the line. Because all the points are below the reference line, we know that the price distribution is skewed right.

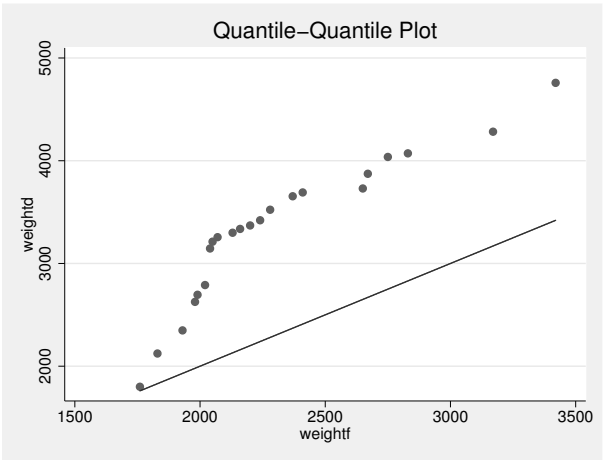
◁

qqplot

▷ Example 3

We have data on the weight and country of manufacture of 74 automobiles. We wish to compare the distributions of weights for domestic and foreign automobiles:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. generate weightd=weight if !foreign
(22 missing values generated)
. generate weightf=weight if foreign
(52 missing values generated)
. qqplot weightd weightf
```



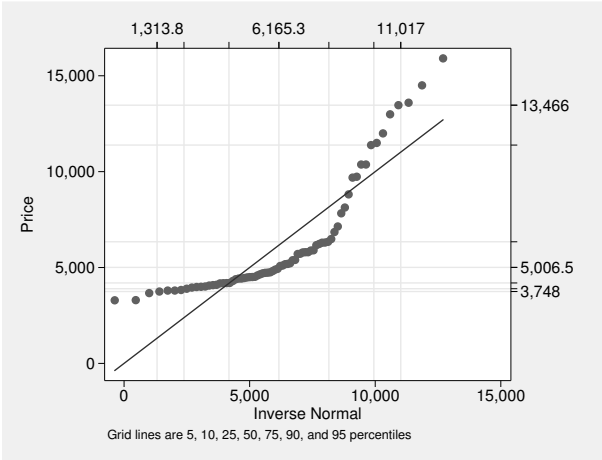
◁

qnorm

▷ Example 4

Continuing with our price data on 74 automobiles, we now wish to compare the distribution of `price` with the normal distribution:

```
. qnorm price, grid ylabel(, angle(horizontal) axis(1))
> ylabel(, angle(horizontal) axis(2))
```



The result shows that the distributions are different.

◁

❑ Technical note

The idea behind `qnorm` is recommended strongly by Miller (1997): he calls it probit plotting. His recommendations from much practical experience should interest many users. "My recommendation for detecting nonnormality is *probit plotting*" (Miller 1997, 10). "If a deviation from normality cannot be spotted by eye on probit paper, it is not worth worrying about. I never use the Kolmogorov–Smirnov test (or one of its cousins) or the χ^2 test as a preliminary test of normality. They do not tell you how the sample is differing from normality, and I have a feeling they are more likely to detect irregularities in the middle of the distribution than in the tails" (Miller 1997, 13–14).

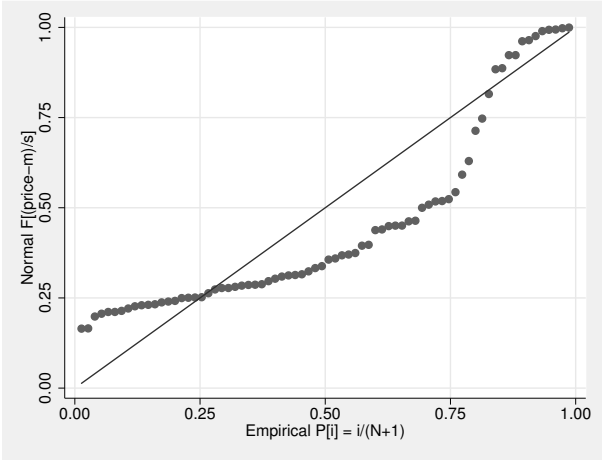
❑

pnorm

▷ Example 5

Quantile–normal plots emphasize the tails of the distribution. Normal probability plots put the focus on the center of the distribution:

```
. pnorm price, grid
```

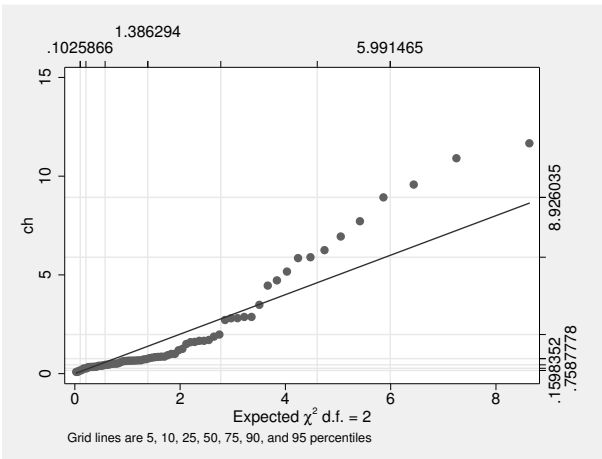


qchi

▷ Example 6

Suppose that we want to examine the distribution of the sum of squares of `price` and `mpg`, standardized for their variances.

```
. egen c1 = std(price)
. egen c2 = std(mpg)
. generate ch = c1^2 + c2^2
. qchi ch, df(2) grid ylabel(, alt axis(2)) xlabel(, alt axis(2))
```



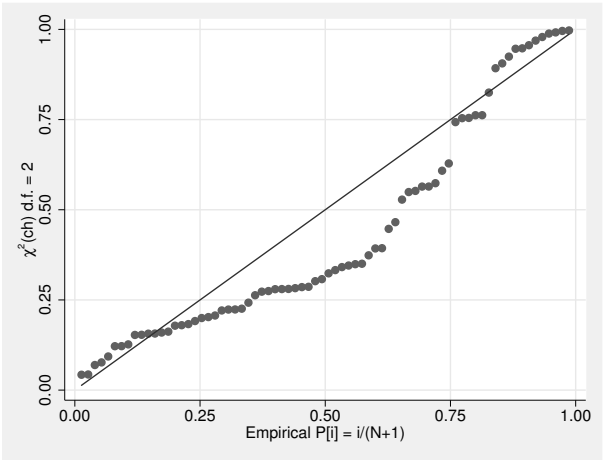
The quadratic form is clearly not χ^2 with 2 degrees of freedom.

pchi

▷ Example 7

We can focus on the center of the distribution by doing a probability plot:

```
. pchi ch, df(2) grid
```



◁

Methods and formulas

`symplot`, `quantile`, `qqplot`, `qnorm`, `pnorm`, `qchi`, and `pchi` are implemented as ado-files. Let $x_{(1)}$, $x_{(2)}$, ..., $x_{(N)}$ be the data sorted in ascending order.

If a continuous variable, x, has a cumulative distribution function $F(x) = P(X \leq x) = p$, the quantiles x_{p_i} are such that $F(x_{p_i}) = p_i$. For example, if $p_i = 0.5$, then $x_{0.5}$ is the median. When we plot data, the probabilities, p_i, are often referred to as plotting positions. There are many different conventions for choice of plotting positions, given $x_{(1)} \leq \cdots \leq x_{(N)}$. Most belong to the family $(i-a)/(N-2a+1)$. $a = 0.5$ (suggested by Hazen) and $a = 0$ (suggested by Weibull) are popular choices.

For a wider discussion of the calculation of plotting positions, see Cox (2002).

`symplot` plots median $- x_{(i)}$ versus $x_{(N+1-i)} -$ median.

`quantile` plots $x_{(i)}$ versus $(i - 0.5)/N$ (the Hazen position).

`qnorm` plots $x_{(i)}$ against q_i, where $q_i = \Phi^{-1}(p_i)$, Φ is the cumulative normal distribution, and $p_i = i/(N+1)$ (the Weibull position).

`pnorm` plots $\Phi\{(x_i - \widehat{\mu})/\widehat{\sigma}\}$ versus $p_i = i/(N+1)$, where $\widehat{\mu}$ is the mean of the data and $\widehat{\sigma}$ is the standard deviation.

`qchi` and `pchi` are similar to `qnorm` and `pnorm`; the cumulative χ^2 distribution is used in place of the cumulative normal distribution.

`qqplot` is just a two-way scatterplot of one variable against the other after both variables have been sorted into ascending order, and both variables have the same number of nonmissing observations. If the variables have unequal numbers of nonmissing observations, interpolated values of the variable with more data are plotted against the variable with fewer data.

Ramanathan Gnanadesikan (1932–) was born in Madras. He obtained degrees from the Universities of Madras and North Carolina. He worked in industry at Procter & Gamble, Bell Labs, and Bellcore, as well as in universities, retiring from Rutgers in 1998. Among many contributions to statistics he is especially well known for work on probability plotting, robustness, outlier detection, clustering, classification, and pattern recognition.

Martin Bradbury Wilk (1922–) was born in Montreal. He obtained degrees in chemical engineering and statistics from McGill and Iowa State Universities. After holding several statistics-related posts in industry and at universities (including periods at Princeton, Bell Labs, and Rutgers), Wilk was appointed Chief Statistician at Statistics Canada (1980–1986). He is especially well known for his work with Gnanadesikan on probability plotting and with Shapiro on tests for normality.

Acknowledgments

We thank Peter A. Lachenbruch of the Department of Public Health, Oregon State University, for writing the original version of `qchi` and `pchi`. Patrick Royston of the MRC Clinical Trials Unit, London, also published a similar command in the *Stata Technical Bulletin* (Royston 1996).

Title

display — Substitute for a hand calculator

Syntax

`display` *exp*

Description

`display` displays strings and values of scalar expressions.

`display` really has many more features and a more complex syntax diagram, but the diagram shown above is adequate for interactive use. For a full discussion of `display`'s capabilities, see [P] **display**.

Remarks

`display` can be used as a substitute for a hand calculator.

▷ Example 1

`display 2+2` produces the output `4`. Stata variables may also appear in the expression, such as in `display myvar/2`. Because `display` works only with scalars, the resulting calculation is performed only for the first observation. You could type `display myvar[10]/2` to display the calculation for the 10th observation. Here are more examples:

```
. display sqrt(2)/2
.70710678
. display normal(-1.1)
.13566606
. di (57.2-3)/(12-2)
5.42
. display myvar/10
7
. display myvar[10]/2
3.5
```

◁

Title

do — Execute commands from a file

Syntax

{do | run} *filename* [*arguments*] [, nostop]

Menu

File > Do...

Description

do and run cause Stata to execute the commands stored in *filename* just as if they were entered from the keyboard. do echoes the commands as it executes them, whereas run is silent. If *filename* is specified without an extension, .do is assumed.

Option

nostop allows the do-file to continue executing even if an error occurs. Normally, Stata stops executing the do-file when it detects an error (nonzero return code).

Remarks

You can create *filename* (called a *do-file*) using Stata's Do-file Editor; see [R] **doedit**. This file will be a standard ASCII (text) file. A complete discussion of do-files can be found in [U] **16 Do-files**.

You can also create *filename* by using a non-Stata text editor; see [D] **shell** for a way to invoke your favorite editor from inside Stata. Make sure that you save the file in ASCII format.

If the path or *filename* contains spaces, it should be enclosed in double quotes.

Title

doedit — Edit do-files and other text files

Syntax

`doedit` [*filename*]

Menu

Window > Do-file Editor

Description

`doedit` opens a text editor that lets you edit do-files and other text files.

The Do-file Editor lets you submit several commands to Stata at once.

Remarks

Clicking on the **Do-file Editor** button is equivalent to typing `doedit`.

`doedit`, typed by itself, invokes the Editor with an empty document. If you specify *filename*, that file is displayed in the Editor.

You may have more than one Do-file Editor open at once. Each time you submit the `doedit` command, a new window will be opened.

A tutorial discussion of `doedit` can be found in the *Getting Started with Stata* manual. Read [U] **16 Do-files** for an explanation of do-files, and then read [GSW] **13 Using the Do-file Editor—automating Stata** to learn how to use the Do-file Editor to create and execute do-files.

dotplot — Comparative scatterplots

Syntax

Dotplot of varname, with one column per value of groupvar

```
dotplot varname [if] [in] [, options]
```

Dotplot for each variable in varlist, with one column per variable

```
dotplot varlist [if] [in] [, options]
```

options	Description
Options	
`over(`*groupvar*`)`	display one columnar dotplot for each value of *groupvar*
`nx(#)`	horizontal dot density; default is `nx(0)`
`ny(#)`	vertical dot density; default is `ny(35)`
`incr(#)`	label every # group; default is `incr(1)`
`mean` | `median`	plot a horizontal line of pluses at the mean or median
`bounded`	use minimum and maximum as boundaries
`bar`	plot horizontal dashed lines at shoulders of each group
`nogroup`	use the actual values of *yvar*
`center`	center the dot for each column
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Graphics > Distributional graphs > Distribution dotplot

Description

A dotplot is a scatterplot with values grouped together vertically ("binning", as in a histogram) and with plotted points separated horizontally. The aim is to display all the data for several variables or groups in one compact graphic.

In the first syntax, `dotplot` produces a columnar dotplot of *varname*, with one column per value of *groupvar*. In the second syntax, `dotplot` produces a columnar dotplot for each variable in *varlist*, with one column per variable; `over(`*groupvar*`)` is not allowed. In each case, the "dots" are plotted as small circles to increase readability.

Options

Options

`over(`*groupvar*`)` identifies the variable for which `dotplot` will display one columnar dotplot for each value of *groupvar*.

`nx(#)` sets the horizontal dot density. A larger value of # will increase the dot density, reducing the horizontal separation between dots. This option will increase the separation between columns if two or more groups or variables are used.

`ny(#)` sets the vertical dot density (number of "bins" on the y axis). A larger value of # will result in more bins and a plot that is less spread out horizontally. # should be determined in conjunction with `nx()` to give the most pleasing appearance.

`incr(#)` specifies how the x axis is to be labeled. `incr(1)`, the default, labels all groups. `incr(2)` labels every second group.

[`mean` | `median`] plots a horizontal line of pluses at the mean or median of each group.

`bounded` forces the minimum and maximum of the variable to be used as boundaries of the smallest and largest bins. It should be used with one variable whose support is not the whole of the real line and whose density does not tend to zero at the ends of its support, for example, a uniform random variable or an exponential random variable.

`bar` plots horizontal dashed lines at the "shoulders" of each group. The shoulders are taken to be the upper and lower quartiles unless `mean` has been specified; here they will be the mean plus or minus the standard deviation.

`nogroup` uses the actual values of *yvar* rather than grouping them (the default). This option may be useful if *yvar* takes on only a few values.

`center` centers the dots for each column on a hidden vertical line.

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

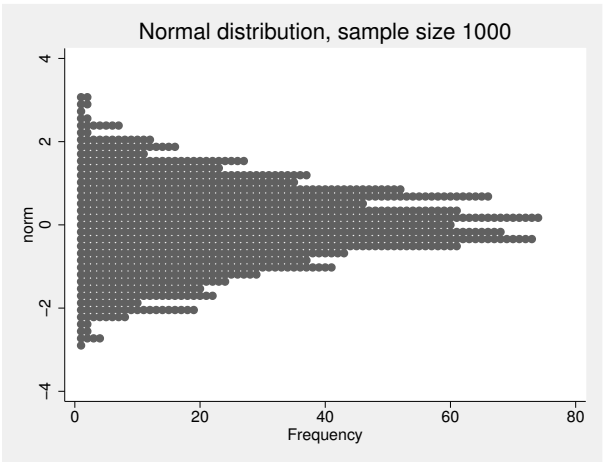
Remarks

`dotplot` produces a figure that has elements of a boxplot, a histogram, and a scatterplot. Like a boxplot, it is most useful for comparing the distributions of several variables or the distribution of 1 variable in several groups. Like a histogram, the figure provides a crude estimate of the density, and, as with a scatterplot, each symbol (dot) represents 1 observation.

Example 1

`dotplot` may be used as an alternative to Stata's histogram graph for displaying the distribution of one variable.

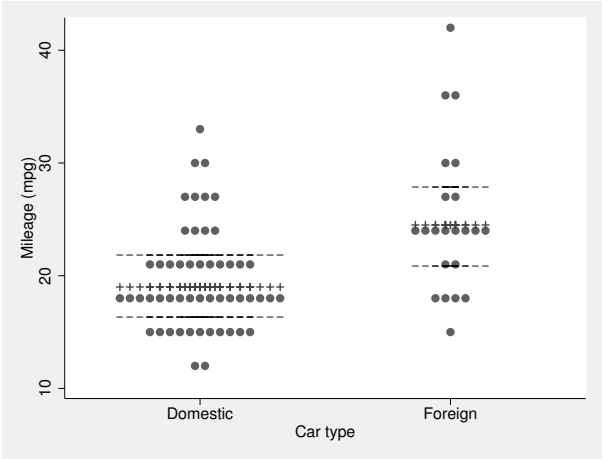
```
. set seed 123456789
. set obs 1000
. generate norm = rnormal()
. dotplot norm, title("Normal distribution, sample size 1000")
```



Example 2

The `over()` option lets us use `dotplot` to compare the distribution of one variable within different levels of a grouping variable. The `center`, `median`, and `bar` options create a graph that may be compared with Stata's boxplot; see [G-2] **graph box**. The next graph illustrates this option with Stata's automobile dataset.

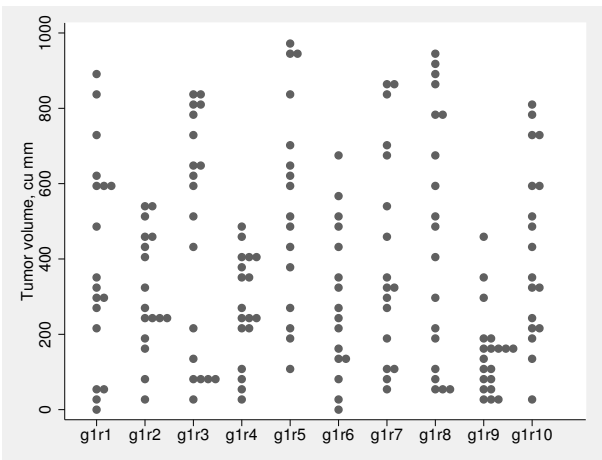
```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. dotplot mpg, over(foreign) nx(25) ny(10) center median bar
```



Example 3

The second version of `dotplot` lets us compare the distribution of several variables. In the next graph, all 10 variables contain measurements on tumor volume.

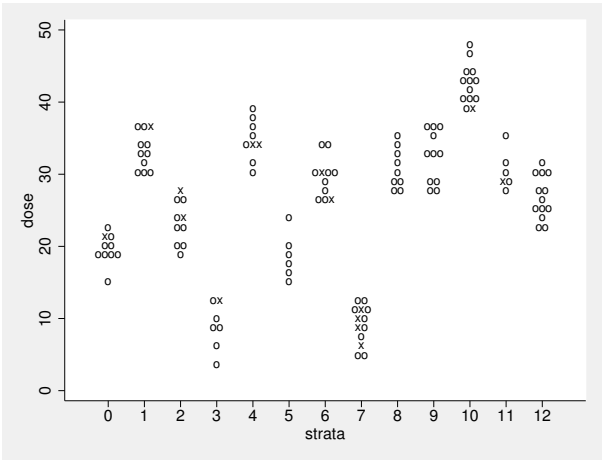
```
. use http://www.stata-press.com/data/r12/dotgr
. dotplot g1r1-g1r10, ytitle("Tumor volume, cu mm")
```



Example 4

When using the first form with the `over()` option, we can encode a third dimension in a dotplot by using a different plotting symbol for different groups. The third dimension cannot be encoded with a varlist. The example is of a hypothetical matched case–control study. The next graph shows the exposure of each individual in each matched stratum. Cases are marked by the letter 'x', and controls are marked by the letter 'o'.

```
. use http://www.stata-press.com/data/r12/dotdose
. label define symbol 0 "o" 1 "x"
. label values case symbol
. dotplot dose, over(strata) m(none) mlabel(case) mlabp(0) center
```

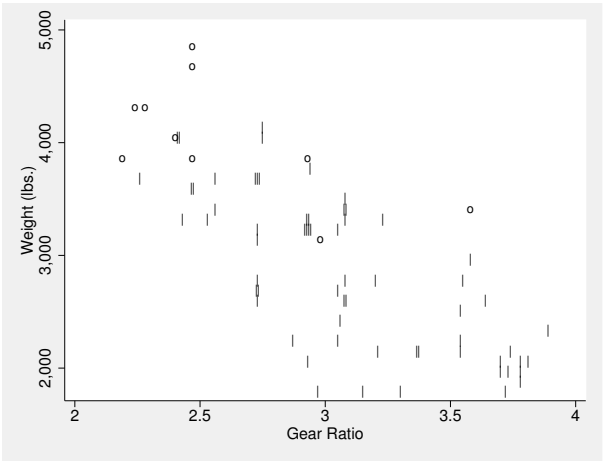


Example 5

`dotplot` can also be used with two virtually continuous variables as an alternative to jittering the data to distinguish ties. We must use the `xlabel()` option, because otherwise `dotplot` will attempt to label too many points on the x axis. It is often useful in such instances to use a value of `nx` that is smaller than the default. That was not necessary in this example, partly because of our choice of symbols.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. generate byte hi_price = (price>10000) if price < .
. label define symbol 0 "|" 1 "o"
. label values hi_price symbol
```

```
. dotplot weight, over(gear_ratio) m(none) mlabel(hi_price) mlabp(0) center
> xlabel(#5)
```

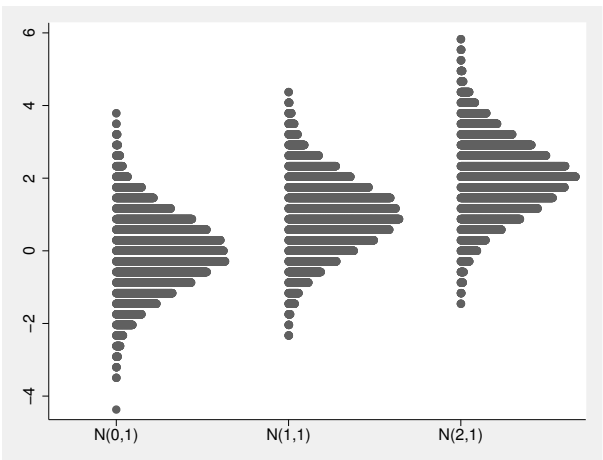


◁

▷ Example 6

The following figure is included mostly for aesthetic reasons. It also demonstrates `dotplot`'s ability to cope with even very large datasets. The sample size for each variable is 10,000, so it may take a long time to print.

```
. clear all
. set seed 123456789
. set obs 10000
. gen norm0 = rnormal()
. gen norm1 = rnormal() + 1
. gen norm2 = rnormal() + 2
. label variable norm0 "N(0,1)"
. label variable norm1 "N(1,1)"
. label variable norm2 "N(2,1)"
. dotplot norm0 norm1 norm2
```



◁

Saved results

dotplot saves the following in r():

Scalars

r(nx)	horizontal dot density
r(ny)	vertical dot density

Methods and formulas

dotplot is implemented as an ado-file.

Acknowledgments

dotplot was written by Peter Sasieni of the Wolfson Institute of Preventive Medicine, London, and Patrick Royston of the MRC Clinical Trials Unit, London.

Title

dstdize — Direct and indirect standardization

Syntax

Direct standardization

```
dstdize charvar popvar stratavars [if] [in] , by(groupvars) [dstdize_options]
```

Indirect standardization

```
istdize casevar_s popvar_s stratavars [if] [in] using filename,
    { popvars(casevar_p popvar_p) | rate(ratevar_p {# | crudevar_p}) }
    [istdize_options]
```

dstdize_options	Description
Main	
* `by(`*groupvars*`)`	study populations
`using(`*filename*`)`	use standard population from Stata dataset
`base(`*# | string*`)`	use standard population from a value of grouping variable
`level(#)`	set confidence level; default is `level(95)`
Options	
`saving(`*filename*`)`	save computed standard population distribution as a Stata dataset
`format(%`*fmt*`)`	final summary table display format; default is `%10.0g`
`print`	include table summary of standard population in output
`nores`	suppress saving results in `r()`

*`by(`*groupvars*`)` is required.

istdize_options	Description
Main	
* `popvars(`*casevar*$_p$ *popvar*$_p$`)`	for standard population, *casevar*$_p$ is number of cases and *popvar*$_p$ is number of individuals
* `rate(`*ratevar*$_p$ {*# | crudevar*$_p$}`)`	*ratevar*$_p$ is stratum-specific rates and # or *crudevar*$_p$ is the crude case rate value or variable
`level(#)`	set confidence level; default is `level(95)`
Options	
`by(`*groupvars*`)`	variables identifying study populations
`format(%`*fmt*`)`	final summary table display format; default is `%10.0g`
`print`	include table summary of standard population in output

*Either `popvars(`*casevar*$_p$ *popvar*$_p$`)` or `rate(`*ratevar*$_p$ {*# \| crudevar*$_p$}`)` must be specified.

Menu

dstdize

Statistics > Epidemiology and related > Other > Direct standardization

istdize

Statistics > Epidemiology and related > Other > Indirect standardization

Description

`dstdize` produces standardized rates for *charvar*, which are defined as a weighted average of the stratum-specific rates. These rates can be used to compare the characteristic *charvar* across different populations identified by *groupvars*. Weights used in the standardization are given by *popvar*; the strata across which the weights are to be averaged are defined by *stratavars*.

`istdize` produces indirectly standardized rates for a study population based on a standard population. This standardization method is appropriate when the stratum-specific rates for the population being studied are either unavailable or based on small samples and thus are unreliable. The standardization uses the stratum-specific rates of a standard population to calculate the expected number of cases in the study population(s), sums them, and then compares them with the actual number of cases observed. The standard population is in another Stata data file specified by `using` *filename*, and it must contain *popvar* and *stratavars*.

In addition to calculating rates, the indirect standardization command produces point estimates and exact confidence intervals of the study population's standardized mortality ratio (SMR), if death is the event of interest, or the standardized incidence ratio (SIR) for studies of incidence. Here we refer to both ratios as SMR.

$casevar_s$ is the variable name for the study population's number of cases (usually deaths). It must contain integers, and for each group, defined by *groupvar*, each subpopulation identified by *stratavars* must have the same values or missing.

$popvar_s$ identifies the number of subjects represented by each observation in the study population.

stratavars define the strata.

Options for dstdize

Main

`by(`*groupvars*`)` is required for the `dstdize` command; it specifies the variables identifying the study populations. If `base()` is also specified, there must be only one variable in the `by()` group. If you do not have a variable for this option, you can generate one by using something like `gen newvar=1` and then use `newvar` as the argument to this option.

`using(`*filename*`)` or `base(`*#* | *string*`)` may be used to specify the standard population. You may not specify both options. `using(`*filename*`)` supplies the name of a `.dta` file containing the standard population. The standard population must contain the *popvar* and the *stratavars*. If `using()` is not specified, the standard population distribution will be obtained from the data. `base(`*#* | *string*`)` lets you specify one of the values of *groupvar*—either a numeric value or a string—to be used as the standard population. If neither `base()` nor `using()` is specified, the entire dataset is used to determine an estimate of the standard population.

`level(#)` specifies the confidence level, as a percentage, for a confidence interval of the adjusted rate. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

Options

`saving(`*filename*`)` saves the computed standard population distribution as a Stata dataset that can be used in further analyses.

`format(%`*fmt*`)` specifies the format in which to display the final summary table. The default is `%10.0g`.

`print` includes a table summary of the standard population before displaying the study population results.

`nores` suppresses saving results in `r()`. This option is seldom specified. Some saved results are stored in matrices. If there are more groups than `matsize`, `dstdize` will report "matsize too small". Then you can either increase `matsize` or specify `nores`. The `nores` option does not change how results are calculated but specifies that results need not be left behind for use by other programs.

Options for istdize

Main

`popvars(`$casevar_p$ $popvar_p$`)` or `rate(`$ratevar_p$ `#` | $ratevar_p$ $crudevar_p$`)` must be specified with `istdize`. Only one of these two options is allowed. These options are used to describe the standard population's data.

With `popvars(`$casevar_p$ $popvar_p$`)`, $casevar_p$ records the number of cases (deaths) for each stratum in the standard population, and $popvar_p$ records the total number of individuals in each stratum (individuals at risk).

With `rate(`$ratevar_p$ {`#` | $crudevar_p$}`)`, $ratevar_p$ contains the stratum-specific rates. `#` | $crudevar_p$ specifies the crude case rate either by a variable name or by the crude case rate value. If a crude rate variable is used, it must be the same for all observations, although it could be missing for some.

`level(#)` specifies the confidence level, as a percentage, for a confidence interval of the adjusted rate. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

Options

`by(`*groupvars*`)` specifies variables identifying study populations when more than one exists in the data. If this option is not specified, the entire study population is treated as one group.

`format(%`*fmt*`)` specifies the format in which to display the final summary table. The default is `%10.0g`.

`print` outputs a table summary of the standard population before displaying the study population results.

Remarks

Remarks are presented under the following headings:

Direct standardization
Indirect standardization

In epidemiology and other fields, you will often need to compare rates for some characteristic across different populations. These populations often differ on factors associated with the characteristic under study; thus directly comparing overall rates may be misleading.

See van Belle et al. (2004, 642–684), Fleiss, Levin, and Paik (2003, chap. 19), or Kirkwood and Sterne (2003, chap. 25) for a discussion of direct and indirect standardization.

Direct standardization

The direct method of adjusting for differences among populations involves computing the overall rates that would result if, instead of having different distributions, all populations had the same standard distribution. The standardized rate is defined as a weighted average of the stratum-specific rates, with the weights taken from the standard distribution. Direct standardization may be applied only when the specific rates for a given population are available.

`dstdize` generates adjusted summary measures of occurrence, which can be used to compare prevalence, incidence, or mortality rates between populations that may differ on certain characteristics (for example, age, gender, race). These underlying differences may affect the crude prevalence, mortality, or incidence rates.

▷ Example 1

We have data (Rothman 1986, 42) on mortality rates for Sweden and Panama for 1962, and we wish to compare mortality in these two countries:

```
. use http://www.stata-press.com/data/r12/mortality
(1962 Mortality, Sweden & Panama)
. describe
Contains data from http://www.stata-press.com/data/r12/mortality.dta
  obs:             6                          1962 Mortality, Sweden & Panama
 vars:             4                          14 Apr 2011 16:18
 size:            90
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
nation          str6   %9s                    Nation
age_category    byte   %9.0g       age_lbl    Age Category
population      float  %10.0gc                Population in Age Category
deaths          float  %9.0gc                 Deaths in Age Category
-------------------------------------------------------------------------------
Sorted by:
```

```
. list, sepby(nation) abbrev(12) divider
```

	nation	age_category	population	deaths
1.	Sweden	0 - 29	3145000	3,523
2.	Sweden	30 - 59	3057000	10,928
3.	Sweden	60+	1294000	59,104
4.	Panama	0 - 29	741,000	3,904
5.	Panama	30 - 59	275,000	1,421
6.	Panama	60+	59,000	2,456

We divide the total number of cases in the population by the population to obtain the *crude rate*:

```
. collapse (sum) pop deaths, by(nation)
. list, abbrev(10) divider
```

	nation	population	deaths
1.	Panama	1075000	7,781
2.	Sweden	7496000	73,555

```
. generate crude = deaths/pop
. list, abbrev(10) divider
```

	nation	population	deaths	crude
1.	Panama	1075000	7,781	.0072381
2.	Sweden	7496000	73,555	.0098126

If we examine the total number of deaths in the two nations, the total crude mortality rate in Sweden is higher than that in Panama. From the original data, we see one possible explanation: Swedes are older than Panamanians, making direct comparison of the mortality rates difficult.

Direct standardization lets us remove the distortion caused by the different age distributions. The adjusted rate is defined as the weighted sum of the crude rates, where the weights are given by the standard distribution. Suppose that we wish to standardize these mortality rates to the following age distribution:

```
. use http://www.stata-press.com/data/r12/1962, clear
(Standard Population Distribution)
. list, abbrev(12) divider
```

	age_category	population
1.	0 - 29	.35
2.	30 - 59	.35
3.	60+	.3

```
. sort age_cat
. save 1962, replace
file 1962.dta saved
```

If we multiply the above weights for the age strata by the crude rate for the corresponding age category, the sum gives us the standardized rate.

```
. use http://www.stata-press.com/data/r12/mortality
(1962 Mortality, Sweden & Panama)
. generate crude=deaths/pop
. drop pop
. sort age_cat
. merge m:1 age_cat using 1962
age_category was byte now float
    Result                           # of obs.
    -----------------------------------------
    not matched                             0
    matched                                 6  (_merge==3)
    -----------------------------------------
. list, sepby(age_category) abbrev(12)
```

	nation	age_category	deaths	crude	population	_merge
1.	Sweden	0 - 29	3,523	.0011202	.35	matched (3)
2.	Panama	0 - 29	3,904	.0052686	.35	matched (3)
3.	Sweden	30 - 59	10,928	.0035747	.35	matched (3)
4.	Panama	30 - 59	1,421	.0051673	.35	matched (3)
5.	Panama	60+	2,456	.0416271	.3	matched (3)
6.	Sweden	60+	59,104	.0456754	.3	matched (3)

```
. generate product = crude*pop
. by nation, sort: egen adj_rate = sum(product)
. drop _merge
. list, sepby(nation)
```

	nation	age_ca~y	deaths	crude	popula~n	product	adj_rate
1.	Panama	30 - 59	1,421	.0051673	.35	.0018085	.0161407
2.	Panama	0 - 29	3,904	.0052686	.35	.001844	.0161407
3.	Panama	60+	2,456	.0416271	.3	.0124881	.0161407
4.	Sweden	0 - 29	3,523	.0011202	.35	.0003921	.0153459
5.	Sweden	60+	59,104	.0456754	.3	.0137026	.0153459
6.	Sweden	30 - 59	10,928	.0035747	.35	.0012512	.0153459

Comparing the standardized rates indicates that the Swedes have a slightly lower mortality rate.

To perform the above analysis with `dstdize`, type

```
. use http://www.stata-press.com/data/r12/mortality, clear
(1962 Mortality, Sweden & Panama)
. dstdize deaths pop age_cat, by(nation) using(1962)
```

```
-> nation= Panama

```

The summary table above lets us make a quick inspection of the results within the study populations, and the detail tables give the behavior among the strata within the study populations.

◁

▷ Example 2

We have individual-level data on persons in four cities over several years. Included in the data is a variable indicating whether the person has high blood pressure, together with information on the person's age, sex, and race. We wish to obtain standardized high blood pressure rates for each city for 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined.

Our dataset contains

Sorted by:
```

The `dstdize` command is designed to work with aggregate data but will work with individual-level data only if we create a variable recording the population represented by each observation. For individual-level data, this is one:

```
. gen pop = 1
```

On the next page, we specify `print` to obtain a listing of the standard population and `level(90)` to request 90% rather than 95% confidence intervals. Typing `if year==1990 | year==1992` restricts the data to the two years for both summary tables and the standard population.

```
. dstdize hbp pop age race sex if year==1990 | year==1992, by(city year) print
> level(90)
```

Indirect standardization

Standardization of rates can be performed via the indirect method whenever the stratum-specific rates are either unknown or unreliable. If the stratum-specific rates are known, the direct standardization method is preferred.

To apply the indirect method, you must have the following information:

- The observed number of cases in each population to be standardized, O. For example, if death rates in two states are being standardized using the U.S. death rate for the same period, you must know the total number of deaths in each state.
- The distribution across the various strata for the population being studied, $n_1, \ldots, n_k$. If you are standardizing the death rate in the two states, adjusting for age, you must know the number of individuals in each of the k age groups.
- The stratum-specific rates for the standard population, $p_1, \ldots, p_k$. For example, you must have the U.S. death rate for each stratum (age group).
- The crude rate of the standard population, C. For example, you must have the U.S. mortality rate for the year.

The indirect adjusted rate is then

$$R_{\text{indirect}} = C\frac{O}{E}$$

where E is the expected number of cases (deaths) in each population. See *Methods and formulas* for a more detailed description of calculations.

▷ Example 3

This example is borrowed from Kahn and Sempos (1989, 95–105). We want to compare 1970 mortality rates in California and Maine, adjusting for age. Although we have age-specific population counts for the two states, we lack age-specific death rates. Direct standardization is not feasible here. We can use the U.S. population census data for the same year to produce indirectly standardized rates for these two states.

From the U.S. census, the standard population for this example was entered into Stata and saved in `popkahn.dta`.

```
. use http://www.stata-press.com/data/r12/popkahn, clear
. list age pop deaths rate, sep(4)
```

	age	population	deaths	rate
1.	<15	57,900,000	103,062	.00178
2.	15-24	35,441,000	45,261	.00128
3.	25-34	24,907,000	39,193	.00157
4.	35-44	23,088,000	72,617	.00315
5.	45-54	23,220,000	169,517	.0073
6.	55-64	18,590,000	308,373	.01659
7.	65-74	12,436,000	445,531	.03583
8.	75+	7,630,000	736,758	.09656

The standard population contains for each age stratum the total number of individuals (`pop`) and both the age-specific mortality rate (`rate`) and the number of deaths. The standard population need not contain all three. If we have only the age-specific mortality rate, we can use the `rate(`*ratevar*$_p$ *crudevar*$_p$`)` or `rate(`*ratevar*$_p$ *#*`)` option, where *crudevar*$_p$ refers to the variable containing the total population's crude death rate or *#* is the total population's crude death rate.

Now let's look at the states' data (study population):

```
. use http://www.stata-press.com/data/r12/kahn
. list, sep(4)
```

	state	age	populat~n	death	st	death_~e
1.	California	<15	5,524,000	166,285	1	.0016
2.	California	15-24	3,558,000	166,285	1	.0013
3.	California	25-34	2,677,000	166,285	1	.0015
4.	California	35-44	2,359,000	166,285	1	.0028
5.	California	45-54	2,330,000	166,285	1	.0067
6.	California	55-64	1,704,000	166,285	1	.0154
7.	California	65-74	1,105,000	166,285	1	.0328
8.	California	75+	696,000	166,285	1	.0917
9.	Maine	<15	286,000	11,051	2	.0019
10.	Maine	15-24	168,000	.	2	.0011
11.	Maine	25-34	110,000	.	2	.0014
12.	Maine	35-44	109,000	.	2	.0029
13.	Maine	45-54	110,000	.	2	.0069
14.	Maine	55-64	94,000	.	2	.0173
15.	Maine	65-74	69,000	.	2	.039
16.	Maine	75+	46,000	.	2	.1041

For each state, the number of individuals in each stratum (age group) is contained in the `pop` variable. The `death` variable is the total number of deaths observed in the state during the year. It must have the same value for all observations in the group, as for California, or it could be missing in all but one observation per group, as for Maine.

To match these two datasets, the strata variables must have the same name in both datasets and ideally the same levels. If a level is missing from either dataset, that level will not be included in the standardization.

With `kahn.dta` in memory, we now execute the command. We will use the `print` option to obtain the standard population's summary table, and because we have both the standard population's age-specific count and deaths, we will specify the `popvars(`*casevar*$_p$ *popvar*$_p$`)` option. Or, we could specify the `rate(rate 0.00945)` option because we know that 0.00945 is the U.S. crude death rate for 1970.

```
. istdize death pop age using http://www.stata-press.com/data/r12/popkahn,
> by(state) pop(deaths pop) print

Saved results

`dstdize` saves the following in `r()`:

Scalars

`r(k)`	number of populations

Macros

`r(by)`	variable names specified in `by()`
`r(c#)`	values of `r(by)` for #th group

Matrices

`r(se)`	standard errors of adjusted rates
`r(ub)`	upper bounds of confidence intervals for adjusted rates
`r(lb)`	lower bounds of confidence intervals for adjusted rates
`r(Nobs)`	$1 \times k$ vector of number of observations
`r(crude)`	$1 \times k$ vector of crude rates (*)
`r(adj)`	$1 \times k$ vector of adjusted rates (*)

(*) If, in a group, the number of observations is 0, then 9 is stored for the corresponding crude and adjusted rates.

Methods and formulas

`dstdize` and `istdize` are implemented as ado-files.

The directly standardized rate, S_{R}, is defined by

$$S_{\mathrm{R}} = \frac{\sum_{i=1}^{k} w_i R_i}{\sum_{i=1}^{k} w_i}$$

(Rothman 1986, 44), where R_i is the stratum-specific rate in stratum i and w_i is the weight for stratum i derived from the standard population.

If n_i is the population of stratum i, the standard error, $\mathrm{se}(S_{\mathrm{R}})$, in stratified sampling for proportions (ignoring the finite population correction) is

$$\mathrm{se}(S_{\mathrm{R}}) = \frac{1}{\sum w_i} \sqrt{\sum_{i=1}^{k} \frac{{w_i}^2 R_i(1-R_i)}{n_i}}$$

(Cochran 1977, 108), from which the confidence intervals are calculated.

For indirect standardization, define O as the observed number of cases in each population to be standardized; $n_1, \ldots, n_k$ as the distribution across the various strata for the population being studied; $R_1, \ldots, R_k$ as the stratum-specific rates for the standard population; and C as the crude rate of the standard population. The expected number of cases (deaths), E, in each population is obtained by applying the standard population stratum-specific rates, $R_1, \ldots, R_k$, to the study populations:

$$E = \sum_{i=1}^{k} n_i R_i$$

The indirectly adjusted rate is then

$$R_{\text{indirect}} = C\frac{O}{E}$$

and O/E is the study population's SMR if death is the event of interest or the SIR for studies of disease (or other) incidence.

The exact confidence interval is calculated for each estimated SMR by assuming a Poisson process as described in Breslow and Day (1987, 69–71). These intervals are obtained by first calculating the upper and lower bounds for the confidence interval of the Poisson-distributed observed events, O—say, L and U, respectively—and then computing $\text{SMR}_L = L/E$ and $\text{SMR}_U = U/E$.

Acknowledgments

Title

dydx — Calculate numeric derivatives and integrals

Syntax

Derivatives of numeric functions

`dydx` *yvar xvar* [*if*] [*in*] `,` `generate(`*newvar*`)` [*dydx_options*]

Integrals of numeric functions

`integ` *yvar xvar* [*if*] [*in*] [`,` *integ_options*]

dydx_options	Description
Main	
* `generate(`*newvar*`)`	create variable named *newvar*
`replace`	overwrite the existing variable

* `generate(`*newvar*`)` is required.

integ_options	Description
Main	
`generate(`*newvar*`)`	create variable named *newvar*
`trapezoid`	use trapezoidal rule to compute integrals; default is cubic splines
`initial(#)`	initial value of integral; default is `initial(0)`
`replace`	overwrite the existing variable

`by` is allowed with `dydx` and `integ`; see [D] **by**.

Menu

dydx

Data > Create or change data > Other variable-creation commands > Calculate numerical derivatives

integ

Data > Create or change data > Other variable-creation commands > Calculate numeric integrals

Description

`dydx` and `integ` calculate derivatives and integrals of numeric "functions".

Options

Main

`generate(`*newvar*`)` specifies the name of the new variable to be created. It must be specified with `dydx`.

`trapezoid` requests that the trapezoidal rule [the sum of $(x_i - x_{i-1})(y_i + y_{i-1})/2$] be used to compute integrals. The default is cubic splines, which give superior results for most smooth functions; for irregular functions, `trapezoid` may give better results.

`initial(#)` specifies the initial condition for calculating definite integrals; see *Methods and formulas* below. The default is `initial(0)`.

`replace` specifies that if an existing variable is specified for `generate()`, it should be overwritten.

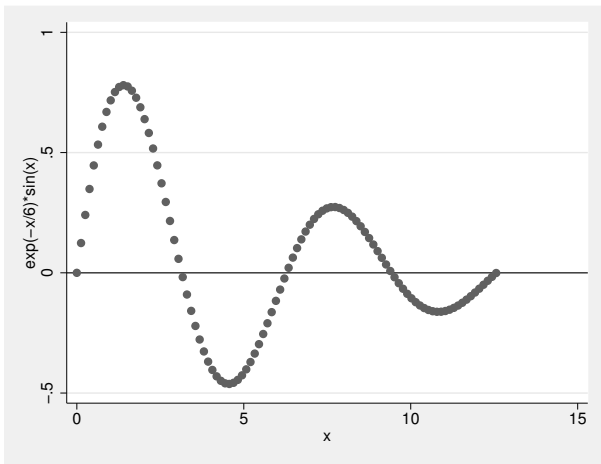
Remarks

`dydx` and `integ` lets you extend Stata's graphics capabilities beyond data analysis and into mathematics. (See Gould [1993] for another command that draws functions.)

▷ Example 1

We graph $y = e^{-x/6}\sin(x)$ over the interval $[0, 12.56]$:

```
. range x 0 12.56 100
obs was 0, now 100
. generate y = exp(-x/6)*sin(x)
. label variable y "exp(-x/6)*sin(x)"
. twoway connected y x, connect(i) yline(0)
```

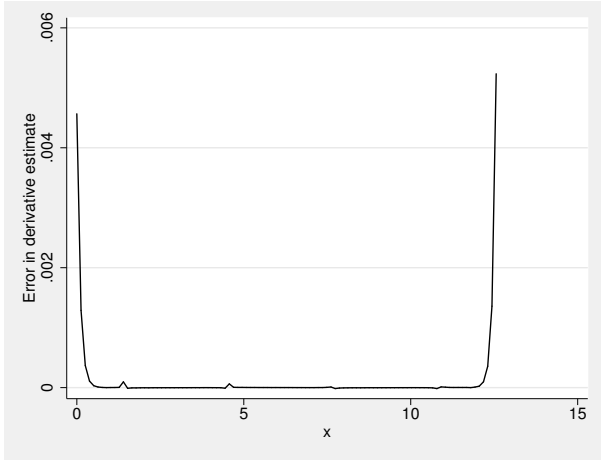


We estimate the derivative by using `dydx` and compute the relative difference between this estimate and the true derivative.

```
. dydx y x, gen(dy)
. generate dytrue = exp(-x/6)*(cos(x) - sin(x)/6)
. generate error = abs(dy - dytrue)/dytrue
```

The error is greatest at the endpoints, as we would expect. The error is approximately 0.5% at each endpoint, but the error quickly falls to less than 0.01%.

```
. label variable error "Error in derivative estimate"
. twoway line error x, ylabel(0(.002).006)
```

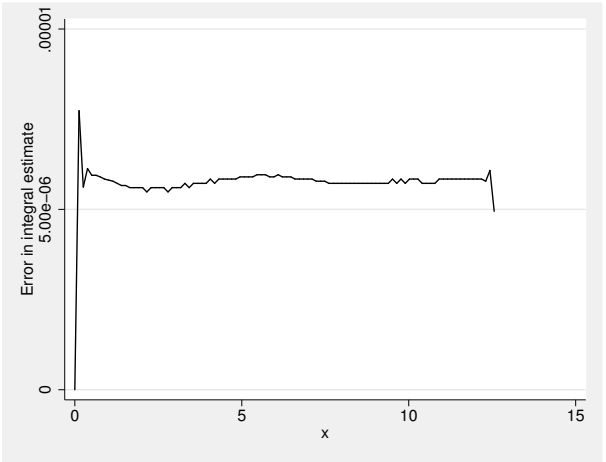


We now estimate the integral by using `integ`:

```
. integ y x, gen(iy)
number of points = 100
integral         = .85316396
. generate iytrue = (36/37)*(1 - exp(-x/6)*(cos(x) + sin(x)/6))
. display iytrue[_N]
.85315901
. display abs(r(integral) - iytrue[_N])/iytrue[_N]
5.799e-06
. generate diff = iy - iytrue
```

The relative difference between the estimate [stored in `r(integral)`] and the true value of the integral is about 6×10^{-6}. A graph of the absolute difference (`diff`) is shown below. Here error is cumulative. Again most of the error is due to a relatively poorer fit near the endpoints.

```
. label variable diff "Error in integral estimate"
. twoway line diff x, ylabel(0(5.00e-06).00001)
```



Saved results

`dydx` saves the following in `r()`:

Macros

`r(y)`	name of *yvar*

`integ` saves the following in `r()`:

Scalars

`r(N_points)`	number of unique x points
`r(integral)`	estimate of the integral

Methods and formulas

`dydx` and `integ` are implemented as ado-files.

Consider a set of data points, $(x_1, y_1), \ldots, (x_n, y_n)$, generated by a function $y = f(x)$. `dydx` and `integ` first fit these points with a cubic spline, which is then analytically differentiated (integrated) to give an approximation for the derivative (integral) of f.

The cubic spline (see, for example, Press et al. [2007]) consists of $n-1$ cubic polynomials $P_i(x)$, with the ith one defined on the interval $[x_i, x_{i+1}]$,

$$P_i(x) = y_i a_i(x) + y_{i+1} b_i(x) + y_i'' c_i(x) + y_{i+1}'' d_i(x)$$

where

$$a_i(x) = \frac{x_{i+1} - x}{x_{i+1} - x_i} \qquad b_i(x) = \frac{x - x_i}{x_{i+1} - x_i}$$

$$c_i(x) = \frac{1}{6}(x_{i+1} - x_i)^2 a_i(x)[\{a_i(x)\}^2 - 1] \qquad d_i(x) = \frac{1}{6}(x_{i+1} - x_i)^2 b_i(x)[\{b_i(x)\}^2 - 1]$$

and y_i'' and y_{i+1}'' are constants whose values will be determined as described below. The notation for these constants is justified because $P_i''(x_i) = y_i''$ and $P_i''(x_{i+1}) = y_{i+1}''$.

Because $a_i(x_i) = 1$, $a_i(x_{i+1}) = 0$, $b_i(x_i) = 0$, and $b_i(x_{i+1}) = 1$. Therefore, $P_i(x_i) = y_i$, and $P_i(x_{i+1}) = y_{i+1}$. Thus the P_i jointly define a function that is continuous at the interval boundaries. The first derivative should be continuous at the interval boundaries; that is,

$$P_i'(x_{i+1}) = P_{i+1}'(x_{i+1})$$

The above $n - 2$ equations (one equation for each point except the two endpoints) and the values of the first derivative at the endpoints, $P_1'(x_1)$ and $P_{n-1}'(x_n)$, determine the n constants y_i''.

The value of the first derivative at an endpoint is set to the value of the derivative obtained by fitting a quadratic to the endpoint and the two adjacent points; namely, we use

$$P_1'(x_1) = \frac{y_1 - y_2}{x_1 - x_2} + \frac{y_1 - y_3}{x_1 - x_3} - \frac{y_2 - y_3}{x_2 - x_3}$$

and a similar formula for the upper endpoint.

`dydx` approximates $f'(x_i)$ by using $P_i'(x_i)$.

`integ` approximates $F(x_i) = F(x_1) + \int_{x_1}^{x_i} f(x)\,dx$ by using

$$I_0 + \sum_{k=1}^{i-1} \int_{x_k}^{x_{k+1}} P_k(x)\,dx$$

where I_0 (an estimate of $F(x_1)$) is the value specified by the `initial(#)` option. If the `trapezoid` option is specified, `integ` approximates the integral by using the trapezoidal rule:

$$I_0 + \sum_{k=1}^{i-1} \frac{1}{2}\,(x_{k+1} - x_k)(y_{k+1} + y_k)$$

If there are ties among the x_i, the mean of y_i is computed at each set of ties and the cubic spline is fit to these values.

Acknowledgment

The present versions of `dydx` and `integ` were inspired by the `dydx2` command written by Patrick Royston of the MRC Clinical Trials Unit, London.

Title

***eform_option* — Displaying exponentiated coefficients**

Description

An *eform_option* causes the coefficient table to be displayed in exponentiated form: for each coefficient, e^b rather than b is displayed. Standard errors and confidence intervals (CIs) are also transformed.

An *eform_option* is one of the following:

eform_option	Description
`eform(`*string*`)`	use *string* for the column title
`eform`	exponentiated coefficient, *string* is `exp(b)`
`hr`	hazard ratio, *string* is `Haz. Ratio`
`shr`	subhazard ratio, *string* is `SHR`
`irr`	incidence-rate ratio, *string* is `IRR`
`or`	odds ratio, *string* is `Odds Ratio`
`rrr`	relative-risk ratio, *string* is `RRR`

Remarks

▷ Example 1

Here is a simple example of the `or` option with `svy: logit`. The CI for the odds ratio is computed by transforming (by exponentiating) the endpoints of the CI for the corresponding coefficient.

```
. use http://www.stata-press.com/data/r12/nhanes2d
. svy, or: logit highbp female black
(running logit on estimation sample)
```

(*output omitted*)

highbp	Odds Ratio	Linearized Std. Err.	t	P>|t|	[95% Conf.	Interval]
female	.693628	.048676	-5.21	0.000	.6011298	.8003593
black	1.509156	.2089571	2.97	0.006	1.137873	2.001588
_cons	.1350642	.0107783	-25.09	0.000	.1147774	.1589367

We also could have specified the following command and received the same results as above:

```
. svy: logit highbp female black, or
```

Title

eivreg — Errors-in-variables regression

Syntax

`eivreg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`reliab(`*indepvar* # [*indepvar* # [...]]`)`	specify measurement reliability for each *indepvar* measured with error
Reporting	
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

`bootstrap`, `by`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Errors-in-variables regression

Description

`eivreg` fits errors-in-variables regression models.

Options

Model

`reliab(`*indepvar* # [*indepvar* # [...]]`)` specifies the measurement reliability for each independent variable measured with error. Reliabilities are specified as pairs consisting of an independent variable name (a name that appears in *indepvars*) and the corresponding reliability r, $0 < r \leq 1$. Independent variables for which no reliability is specified are assumed to have reliability 1. If the option is not specified, all variables are assumed to have reliability 1, and the result is thus the same as that produced by `regress` (the ordinary least-squares results).

Reporting

`level(#)`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `eivreg` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

For an introduction to errors-in-variables regression, see Draper and Smith (1998, 89–91) or Kmenta (1997, 352–357). Treiman (2009, 258–261) compares the results of errors-in-variables regression with conventional regression.

Errors-in-variables regression models are useful when one or more of the independent variables are measured with additive noise. Standard regression (as performed by `regress`) would underestimate the effect of the variable, and the other coefficients in the model can be biased to the extent that they are correlated with the poorly measured variable. You can adjust for the biases if you know the reliability:

$$r = 1 - \frac{\text{noise variance}}{\text{total variance}}$$

That is, given the model $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$, for some variable $\mathbf{x}_i$ in $\mathbf{X}$, the $\mathbf{x}_i$ is observed with error, $\mathbf{x}_i = \mathbf{x}_i^* + \mathbf{e}$, and the noise variance is the variance of $\mathbf{e}$. The total variance is the variance of $\mathbf{x}_i$.

▷ Example 1

Say that in our automobile data, the weight of cars was measured with error, and the reliability of our measured weight is 0.85. The result of this would be to underestimate the effect of `weight` in a regression of, say, `price` on `weight` and `foreign`, and it would also bias the estimate of the coefficient on `foreign` (because being of foreign manufacture is correlated with the weight of cars). We would ignore all of this if we fit the model with `regress`:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress price weight foreign
```

Source	SS	df	MS	Number of obs =	74
				F(2, 71) =	35.35
Model	316859273	2	158429637	Prob > F =	0.0000
Residual	318206123	71	4481776.38	R-squared =	0.4989
				Adj R-squared =	0.4848
Total	635065396	73	8699525.97	Root MSE =	2117

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	3.320737	.3958784	8.39	0.000	2.531378	4.110096
foreign	3637.001	668.583	5.44	0.000	2303.885	4970.118
_cons	-4942.844	1345.591	-3.67	0.000	-7625.876	-2259.812

With eivreg, we can account for our measurement error:

```
. eivreg price weight foreign, r(weight .85)
```

variable	assumed reliability
weight	0.8500
*	1.0000

Errors-in-variables regression

Number of obs	= 74
F(2, 71)	= 50.37
Prob > F	= 0.0000
R-squared	= 0.6483
Root MSE	= 1773.54

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	4.31985	.431431	10.01	0.000	3.459601	5.180099
foreign	4637.32	624.5362	7.43	0.000	3392.03	5882.609
_cons	-8257.017	1452.086	-5.69	0.000	-11152.39	-5361.639

The effect of weight is increased—as we knew it would be—and here the effect of foreign manufacture is also increased. A priori, we knew only that the estimate of foreign might be biased; we did not know the direction.

◁

❑ Technical note

Swept under the rug in our example is how we would determine the reliability, r. We can easily see that a variable is measured with error, but we may not know the reliability because the ingredients for calculating r depend on the unobserved noise.

For our example, we made up a value for r, and in fact we do not believe that weight is measured with error at all, so the reported eivreg results have no validity. The regress results were the statistically correct results here.

But let's say that we do suspect that weight is measured with error and that we do not know r. We could then experiment with various values of r to describe the sensitivity of our estimates to possible error levels. We may not know r, but r does have a simple interpretation, and we could probably produce a sensible range for r by thinking about how the data were collected.

If the reliability, r, is less than the R^2 from a regression of the poorly measured variable on all the other variables, including the dependent variable, the information might as well not have been collected; no adjustment to the final results is possible. For our automobile data, running a regression of weight on foreign and price would result in an R^2 of 0.6743. Thus the reliability must be at least 0.6743 here. If we specify a reliability that is too small, eivreg will inform us and refuse to fit the model:

```
. eivreg price weight foreign, r(weight .6742)
reliability r() too small
r(399);
```

Returning to our problem of how to estimate r, too small or not, if the measurements are summaries of scaled items, the reliability may be estimated using the alpha command; see [R] **alpha**. If the score is computed from factor analysis and the data are scored using predict's default options (see [MV] **factor postestimation**), the square of the standard deviation of the score is an estimate of the reliability.

❑

❑ Technical note

Consider a model with more than one variable measured with error. For instance, say that our model is that `price` is a function of `weight`, `foreign`, and `mpg` and that both `weight` and `mpg` are measured with error.

```
. eivreg price weight foreign mpg, r(weight .85 mpg .9)

❑

Saved results

`eivreg` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(df_m)`	model degrees of freedom
`e(df_r)`	residual degrees of freedom
`e(r2)`	R-squared
`e(F)`	F statistic
`e(rmse)`	root mean squared error
`e(rank)`	rank of `e(V)`

Macros

`e(cmd)`	`eivreg`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(rellist)`	*indepvars* and associated reliabilities
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

`e(b)`	coefficient vector
`e(Cns)`	constraints matrix
`e(V)`	variance–covariance matrix of the estimators

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`eivreg` is implemented as an ado-file.

Let the model to be fit be

$$\mathbf{y} = \mathbf{X}^*\boldsymbol{\beta} + \mathbf{e}$$
$$\mathbf{X} = \mathbf{X}^* + \mathbf{U}$$

where $\mathbf{X}^*$ are the true values and $\mathbf{X}$ are the observed values. Let $\mathbf{W}$ be the user-specified weights. If no weights are specified, $\mathbf{W} = \mathbf{I}$. If weights are specified, let $\mathbf{v}$ be the specified weights. If `fweight` frequency weights are specified, then $\mathbf{W} = \text{diag}(\mathbf{v})$. If `aweight` analytic weights are specified, then $\mathbf{W} = \text{diag}\{\mathbf{v}/(\mathbf{1}'\mathbf{v})(\mathbf{1}'\mathbf{1})\}$, meaning that the weights are normalized to sum to the number of observations.

The estimates $\mathbf{b}$ of $\boldsymbol{\beta}$ are obtained as $\mathbf{A}^{-1}\mathbf{X}'\mathbf{W}\mathbf{y}$, where $\mathbf{A} = \mathbf{X}'\mathbf{W}\mathbf{X} - \mathbf{S}$. $\mathbf{S}$ is a diagonal matrix with elements $N(1-r_i)s_i^2$. N is the number of observations, r_i is the user-specified reliability coefficient for the ith explanatory variable or 1 if not specified, and s_i^2 is the (appropriately weighted) variance of the variable.

The variance–covariance matrix of the estimators is obtained as $s^2\mathbf{A}^{-1}\mathbf{X}'\mathbf{W}\mathbf{X}\mathbf{A}^{-1}$, where the root mean squared error $s^2 = (\mathbf{y}'\mathbf{W}\mathbf{y} - \mathbf{b}\mathbf{A}\mathbf{b}')/(N-p)$, where p is the number of estimated parameters.

Title

eivreg postestimation — Postestimation tools for eivreg

Description

The following postestimation commands are available after `eivreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	VCE and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` *statistic*]

statistic	Description
Main	
`xb`	linear prediction; the default
`residuals`	residuals
`stdp`	standard error of the prediction
`stdf`	standard error of the forecast
`pr(`*a*`,`*b*`)`	$\Pr(a < y_j < b)$
`e(`*a*`,`*b*`)`	$E(y_j \mid a < y_j < b)$
`ystar(`*a*`,`*b*`)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

where *a* and *b* may be numbers or variables; *a* missing ($a \geq .$) means $-\infty$, and *b* missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, that is, $y_j - \mathbf{x}_j\mathbf{b}$.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation and is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \,|\, a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated. *a* and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

error messages — Error messages and return codes

Description

Whenever Stata detects that something is wrong—that what you typed is uninterpretable, that you are trying to do something you should not be trying to do, or that you requested the impossible—Stata responds by typing a message describing the problem, together with a *return code*. For instance,

```
. lsit
unrecognized command:  lsit
r(199);

. list myvar
variable myvar not found
r(111);

. test a=b
last estimates not found
r(301);
```

In each case, the message is probably sufficient to guide you to a solution. When we typed `lsit`, Stata responded with "unrecognized command". We meant to type `list`. When we typed `list myvar`, Stata responded with "variable myvar not found". There is no variable named `myvar` in our data. When we typed `test a=b`, Stata responded with "last estimates not found". `test` tests hypotheses about previously fit models, and we have not yet fit a model.

The numbers in parentheses in the `r(199)`, `r(111)`, and `r(301)` messages are called the *return codes*. To find out more about these messages, type `search rc #`, where # is the number returned in the parentheses.

▷ Example 1

```
. search rc 301
[P]     error messages . . . . . . . . . . . . . . . . . . . . Return code 301
        last estimates not found;
        You typed an estimation command such as regress without arguments
        or attempted to perform a test or typed predict, but there were no
        previous estimation results.
```

◁

Programmers should see [P] **error** for details on programming error messages.

Title

estat — Postestimation statistics

Syntax

Common subcommands

Display information criteria

```
estat ic [ , n(#) ]
```

Summarize estimation sample

```
estat summarize [ eqlist ] [ , estat_summ_options ]
```

Display covariance matrix estimates

```
estat vce [ , estat_vce_options ]
```

Command-specific subcommands

```
estat subcommand1 [ , options1 ]
estat subcommand2 [ , options2 ]
    ...
```

estat_summ_options	Description
`equation`	display summary by equation
`group`	display summary by group; only after `sem`
`labels`	display variable labels
`noheader`	suppress the header
`noweights`	ignore weights
display_options	control spacing and display of omitted variables and base and empty cells

eqlist is rarely used and specifies the variables, with optional equation name, to be summarized. *eqlist* may be *varlist* or (*eqname*$_1$`:` *varlist*) (*eqname*$_2$`:` *varlist*) .... *varlist* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

estat_vce_options	Description
`covariance`	display as covariance matrix; the default
`correlation`	display as correlation matrix
`equation(`*spec*`)`	display only specified equations
`block`	display submatrices by equation
`diag`	display submatrices by equation; diagonal blocks only
`format(%`*fmt*`)`	display format for covariances and correlations
`nolines`	suppress lines between equations
display_options	control display of omitted variables and base and empty cells

Menu

Statistics > Postestimation > Reports and statistics

Description

`estat` displays scalar- and matrix-valued statistics after estimation; it complements `predict`, which calculates variables after estimation. Exactly what statistics `estat` can calculate depends on the previous estimation command.

Three sets of statistics are so commonly used that they are available after all estimation commands that store the model log likelihood. `estat ic` displays Akaike's and Schwarz's Bayesian information criteria. `estat summarize` summarizes the variables used by the command and automatically restricts the sample to `e(sample)`; it also summarizes the weight variable and cluster structure, if specified. `estat vce` displays the covariance or correlation matrix of the parameter estimates of the previous model.

Option for estat ic

`n(#)` specifies the N to be used in calculating BIC; see [R] **BIC note**.

Options for estat summarize

`equation` requests that the dependent variables and the independent variables in the equations be displayed in the equation-style format of estimation commands, repeating the summary information about variables entered in more than one equation.

`group` displays summary information separately for each group. `group` is only allowed after `sem` with a `group()` variable specified.

`labels` displays variable labels.

`noheader` suppresses the header.

`noweights` ignores the weights, if any, from the previous estimation command. The default when weights are present is to perform a weighted `summarize` on all variables except the weight variable itself. An unweighted `summarize` is performed on the weight variable.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`; see [R] **estimation options**.

Options for estat vce

`covariance` displays the matrix as a variance–covariance matrix; this is the default.

`correlation` displays the matrix as a correlation matrix rather than a variance–covariance matrix. `rho` is a synonym.

`equation(`*spec*`)` selects part of the VCE to be displayed. If *spec* is *eqlist*, the VCE for the listed equations is displayed. If *spec* is *eqlist1* `\` *eqlist2*, the part of the VCE associated with the equations in *eqlist1* (rowwise) and *eqlist2* (columnwise) is displayed. If *spec* is `*`, all equations are displayed. `equation()` implies `block` if `diag` is not specified.

`block` displays the submatrices pertaining to distinct equations separately.

`diag` displays the diagonal submatrices pertaining to distinct equations separately.

`format(%`*fmt*`)` specifies the number format for displaying the elements of the matrix. The default is `format(%10.0g)` for covariances and `format(%8.4f)` for correlations. See [U] **12.5 Formats: Controlling how data are displayed** for more information.

`nolines` suppresses lines between equations.

display_options: `noomitted`, `noemptycells`, `baselevels`, `allbaselevels`; see [R] **estimation options**.

Remarks

`estat` displays a variety of scalar- and matrix-valued statistics after you have estimated the parameters of a model. Exactly what statistics `estat` can calculate depends on the estimation command used, and command-specific statistics are detailed in that command's postestimation manual entry. The rest of this entry discusses three sets of statistics that are available after all estimation commands.

Remarks are presented under the following headings:

estat ic
estat summarize
estat vce

estat ic

`estat ic` calculates two information criteria used to compare models. Unlike likelihood-ratio, Wald, and similar testing procedures, the models need not be nested to compare the information criteria. Because they are based on the log-likelihood function, information criteria are available only after commands that report the log likelihood.

In general, "smaller is better": given two models, the one with the smaller AIC fits the data better than the one with the larger AIC. As with the AIC, a smaller BIC indicates a better-fitting model. For AIC and BIC formulas, see *Methods and formulas*.

▷ Example 1

In [R] **mlogit**, we fit a model explaining the type of insurance a person has on the basis of age, gender, race, and site of study. Here we refit the model with and without the site dummies and compare the models.

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite
  (output omitted)
. estat ic
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
.	615	-555.8545	-545.5833	8	1107.167	1142.54

Note: N=Obs used in calculating BIC; see **[R] BIC note**

```
. mlogit insure age male nonwhite i.site
  (output omitted)
```

```
. estat ic
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
.	615	-555.8545	-534.3616	12	1092.723	1145.783

Note: N=Obs used in calculating BIC; see **[R] BIC note**

The AIC indicates that the model including the site dummies fits the data better, whereas the BIC indicates the opposite. As is often the case, different model-selection criteria have led to conflicting conclusions.

◁

❑ Technical note

`glm` and `binreg, ml` report a slightly different version of AIC and BIC; see [R] **glm** for the formulas used. That version is commonly used within the GLM literature; see, for example, Hardin and Hilbe (2007). The literature on information criteria is vast; see, among others, Akaike (1973), Sawa (1978), and Raftery (1995). Judge et al. (1985) contains a discussion of using information criteria in econometrics. Royston and Sauerbrei (2008, chap. 2) examine the use of information criteria as an alternative to stepwise procedures for selecting model variables.

❑

estat summarize

Often when fitting a model, you will also be interested in obtaining summary statistics, such as the sample means and standard deviations of the variables in the model. `estat summarize` makes this process simple. The output displayed is similar to that obtained by typing

```
. summarize varlist if e(sample)
```

without the need to type the *varlist* containing the dependent and independent variables.

▷ Example 2

Continuing with the previous multinomial logit model, here we summarize the variables by using `estat summarize`.

```
. estat summarize, noomitted
Estimation sample mlogit                 Number of obs =    615
```

Variable	Mean	Std. Dev.	Min	Max
insure	1.596748	.6225846	1	3
age	44.46832	14.18523	18.1109	86.0725
male	.2504065	.4335998	0	1
nonwhite	.196748	.3978638	0	1
site				
2	.3707317	.4833939	0	1
3	.3138211	.4644224	0	1

◁

The output in the previous example contains all the variables in one table, though `mlogit` presents its results in a multiple-equation format. For models in which the same variables appear in all equations, that is fine; but for other multiple-equation models, we may prefer to have the variables separated by the equation in which they appear. The `equation` option makes this possible.

▷ Example 3

Systems of simultaneous equations typically have different variables in each equation, and the `equation` option of `estat summarize` is helpful in such situations. In example 2 of [R] **reg3**, we have a model of supply and demand. We first refit the model and then call `estat summarize`.

```
. use http://www.stata-press.com/data/r12/supDem
. reg3 (Demand:quantity price pcompete income) (Supply:quantity price praw),
> endog(price)
```

(*output omitted*)

```
. estat summarize, equation
Estimation sample reg3                    Number of obs =     49
```

Variable	Mean	Std. Dev.	Min	Max
depvar				
quantity	12.61818	2.774952	7.71069	20.0477
quantity	12.61818	2.774952	7.71069	20.0477
Demand				
price	32.70944	2.882684	26.3819	38.4769
pcompete	5.929975	3.508264	.207647	11.5549
income	7.811735	4.18859	.570417	14.0077
Supply				
price	32.70944	2.882684	26.3819	38.4769
praw	4.740891	2.962565	.151028	9.79881

The first block of the table contains statistics on the dependent (or, more accurately, left-hand-side) variables, and because we specified quantity as the left-hand-side variable in both equations, it is listed twice. The second block refers to the variables in the first equation we specified, which we labeled "Demand" in our call to `reg3`; and the final block refers to the supply equation.

◁

estat vce

`estat vce` allows you to display the VCE of the parameters of the previously fit model, as either a covariance matrix or a correlation matrix.

Example 4

Returning to the `mlogit` example, we type

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite, nolog
Multinomial logistic regression                 Number of obs   =        615
                                                LR chi2(6)      =      20.54
                                                Prob > chi2     =     0.0022
Log likelihood = -545.58328                     Pseudo R2       =     0.0185
```

        male |  -.00050406   .13248095
    nonwhite |  -.00026145   .01505449   .16861327
       _cons |  -.00562159  -.01686629  -.02474852   .28607591
```

The `block` option is particularly useful for multiple-equation estimators. The first block of output here corresponds to the VCE of the estimated parameters for the first equation—the square roots of the diagonal elements of this matrix are equal to the standard errors of the first equation's parameters. Similarly, the final block corresponds to the VCE of the parameters for the second equation. The middle block shows the covariances between the estimated parameters of the first and second equations. ◁

Saved results

`estat ic` saves the following in `r()`:

Matrices

`r(S)` 1 × 6 matrix of results:
1. sample size
2. log likelihood of null model
3. log likelihood of full model
4. degrees of freedom
5. AIC
6. BIC

`estat summarize` saves the following in `r()`:

Scalars

`r(N_groups)` number of groups (`group` only)

Matrices

`r(stats)` $k \times 4$ matrix of means, standard deviations, minimums, and maximums

`r(stats[_#])` $k \times 4$ matrix of means, standard deviations, minimums, and maximums for group # (`group` only)

`estat vce` saves the following in `r()`:

Matrices

`r(V)` VCE or correlation matrix

Methods and formulas

`estat` is implemented as an ado-file.

Akaike's (1974) information criterion is defined as

$$\mathrm{AIC} = -2\ln L + 2k$$

where $\ln L$ is the maximized log-likelihood of the model and k is the number of parameters estimated. Some authors define the AIC as the expression above divided by the sample size.

Schwarz's (1978) Bayesian information criterion is another measure of fit defined as

$$\text{BIC} = -2\ln L + k\ln N$$

where N is the sample size. See [R] **BIC note** for additional information on calculating and interpreting BIC.

Hirotugu Akaike (1927–2009) was born in Fujinomiya City, Shizuoka Prefecture, Japan. He was the son of a silkworm farmer. He gained BA and DSc degrees from the University of Tokyo. Akaike's career from 1952 at the Institute of Statistical Mathematics in Japan culminated in service as Director General; after 1994, he was Professor Emeritus. His best known work in a prolific career is on what is now known as the Akaike information criterion (AIC), which was formulated to help selection of the most appropriate model from a number of candidates.

Gideon E. Schwarz (1933–2007) was a professor of Statistics at the Hebrew University, Jerusalem. He was born in Salzburg, Austria, and obtained an MSc in 1956 from the Hebrew University and a PhD in 1961 from Columbia University. His interests included stochastic processes, sequential analysis, probability, and geometry. He is best known for the Bayesian information criterion (BIC).

Description

estimates allows you to store and manipulate estimation results:

- You can save estimation results in a file for use in later sessions.
- You can store estimation results in memory so that you can
    a. switch among separate estimation results and
    b. form tables combining separate estimation results.

Remarks

estimates is for use after you have fit a model, be it with regress, logistic, etc. You can use estimates after any estimation command, whether it be an official estimation command of Stata or a user-written one.

estimates has three separate but related capabilities:

1. You can save estimation results in a file on disk so that you can use them later, even in a different Stata session.
2. You can store up to 300 estimation results in memory so that they are at your fingertips.
3. You can make tables comparing any results you have stored in memory.

Remarks are presented under the following headings:

Saving and using estimation results
Storing and restoring estimation results
Comparing estimation results
Jargon

Saving and using estimation results

After you have fit a model, say, with regress, type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ foreign
  (output omitted)
```

You can save the results in a file:

```
. estimates save basemodel
(file basemodel.ster saved)
```

Later, say, in a different session, you can reload those results:

```
. estimates use basemodel
```

The situation is now nearly identical to what it was immediately after you fit the model. You can replay estimation results:

```
. regress
  (output omitted)
```

You can perform tests:

```
. test foreign==0
  (output omitted)
```

And you can use any postestimation command or postestimation capability of Stata. The only difference is that Stata no longer knows what the estimation sample, `e(sample)` in Stata jargon, was. When you reload the estimation results, you might not even have the original data in memory. That is okay. Stata will know to refuse to calculate anything that can be calculated only on the original estimation sample.

If it is important that you use a postestimation command that can be used only on the original estimation sample, there is a way you can do that. You `use` the original data and then use `estimates esample` to tell Stata what the original sample was.

See [R] **estimates save** for details.

Storing and restoring estimation results

Storing and restoring estimation results in memory is much like saving them to disk. You type

```
. estimates store base
```

to save the current estimation results under the name `base`, and you type

```
. estimates restore base
```

to get them back later. You can find out what you have stored by typing

```
. estimates dir
```

Saving estimation results to disk is more permanent than storing them in memory, so why would you want merely to store them? The answer is that, once they are stored, you can use other `estimates` commands to produce tables and reports from them.

See [R] **estimates store** for details about the `estimates store` and `restore` commands.

Comparing estimation results

Let's say that you have done the following:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ
  (output omitted)
. estimates store base
. regress mpg weight displ foreign
  (output omitted)
. estimates store alt
```

You can now get a table comparing the coefficients:

```
. estimates table base alt
```

Variable	base	alt
weight	-.00656711	-.00677449
displacement	.00528078	.00192865
foreign		-1.6006312
_cons	40.084522	41.847949

`estimates table` can do much more; see [R] **estimates table**. Also see [R] **estimates stats**. `estimates stats` works similarly to `estimates table` but produces model comparisons in terms of BIC and AIC.

Jargon

You know that if you fit a model, say, by typing

```
. regress mpg weight displacement
```

then you can later replay the results by typing

```
. regress
```

and you can do tests and calculate other postestimation statistics by typing

```
. test displacement==0
. estat vif
. predict mpghat
```

As a result, we often refer to the *estimation results* or the *current estimation results* or the *most recent estimation results* or the *last estimation results* or the *estimation results in memory*.

With `estimates store` and `estimates restore`, you can have many estimation results in memory. One set of those, the set most recently estimated, or the set most recently restored, are the *current* or *active* estimation results, which you can replay, which you can test, or from which you can calculate postestimation statistics.

Current and *active* are the two words we will use interchangeably from now on.

[P] **_estimates** — Manage estimation results

Title

estimates describe — Describe estimation results

Syntax

```
estimates describe
estimates describe name
estimates describe using filename [ , number(#) ]
```

Menu

Statistics > Postestimation > Manage estimation results > Describe results

Description

`estimates describe` describes the current (active) estimates. Reported are the command line that produced the estimates, any title that was set by `estimates title` (see [R] **estimates title**), and any notes that were added by `estimates notes` (see [R] **estimates notes**).

`estimates describe` *name* does the same but reports results for estimates stored by `estimates store` (see [R] **estimates store**).

`estimates describe using` *filename* does the same but reports results for estimates saved by `estimates save` (see [R] **estimates save**). If *filename* contains multiple sets of estimates (saved in it by `estimates save, append`), the number of sets of estimates is also reported. If *filename* is specified without an extension, `.ster` is assumed.

Option

`number(#)` specifies that the #th set of estimation results from *filename* be described. This assumes that multiple sets of estimation results have been saved in *filename* by `estimates save, append`. The default is `number(1)`.

Remarks

`estimates describe` can be used to describe the estimation results currently in memory,

```
. estimates describe
Estimation results produced by
    . regress mpg weight displ if foreign
```

or to describe results saved by `estimates save` in a `.ster` file:

```
. estimates describe using final
Estimation results "Final results" saved on 12apr2011 14:20, produced by
    . logistic myopic age sex drug1 drug2 if complete==1
Notes:
  1.  Used file patient.dta
  2.  "datasignature myopic age sex drug1 drug2 if complete==1"
      reports 148:5(58763):2252897466:3722318443
  3.  must be reviewed by rgg
```

▷ Example 1

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ if foreign
  (output omitted)
. estimates notes: file `c(filename)'
. datasignature
  74:12(71728):3831085005:1395876116
. estimates notes: datasignature report `r(datasignature)'
. estimates save foreign
file foreign.ster saved
. regress mpg weight displ if !foreign
  (output omitted)
. estimates describe using foreign
  Estimation results saved on 02may2011 10:33, produced by
     . regress mpg weight displ if foreign
  Notes:
    1.  file http://www.stata-press.com/data/r12/auto.dta
    2.  datasignature report 74:12(71728):3831085005:1395876116
```

◁

Saved results

`estimates describe` and `estimates describe` *name* save the following in `r()`:

Macros

`r(title)`	title
`r(cmdline)`	original command line

`estimates describe using` *filename* saves the above and the following in `r()`:

Scalars

`r(datetime)`	`%tc` value of date/time file saved
`r(nestresults)`	number of sets of estimation results in file

Methods and formulas

`estimates describe` is implemented as an ado-file.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates for — Repeat postestimation command across models

Syntax

estimates for *namelist* [, *options*]: *postestimation_command*

where *namelist* is a name, a list of names, _all, or *. A name may be ., meaning the current (active) estimates. _all and * mean the same thing.

options	Description
noheader	do not display title
nostop	do not stop if command fails

Description

estimates for performs *postestimation_command* on each estimation result specified.

Options

noheader suppresses the display of the header as *postestimation_command* is executed each time.

nostop specifies that execution of *postestimation_command* is to be performed on the remaining models even if it fails on some.

Remarks

In the example that follows, we fit a model two different ways, store the results, and then use estimates for to perform the same test on both of them:

▷ Example 1

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. gen fwgt = foreign*weight
. gen dwgt = !foreign*weight
. gen gpm = 1/mpg
. regress gpm fwgt dwgt displ foreign
  (output omitted)
. estimates store reg
. qreg gpm fwgt dwgt displ foreign
  (output omitted)
. estimates store qreg
```

```
. estimates for reg qreg: test fwgt==dwgt
-------------------------------------------------------------------------------
Model reg
-------------------------------------------------------------------------------
 ( 1)  fwgt - dwgt = 0
       F(  1,    69) =    4.87
            Prob > F =    0.0307
-------------------------------------------------------------------------------
Model qreg
-------------------------------------------------------------------------------
 ( 1)  fwgt - dwgt = 0
       F(  1,    69) =    0.07
            Prob > F =    0.7937
```

◁

Methods and formulas

`estimates for` is implemented as an ado-file.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates notes — Add notes to estimation results

Syntax

```
estimates notes: text

estimates notes

estimates notes list [ in noterange ]

estimates notes drop in noterange
```

where *noterange* is # or #/# and where # may be a number, the letter `f` (meaning first), or the letter `l` (meaning last).

Description

`estimates notes:` *text* adds a note to the current (active) estimation results.

`estimates notes` and `estimates notes list` list the current notes.

`estimates notes drop in` *noterange* eliminates the specified notes.

Remarks

After adding or removing notes, if estimates have been stored, do not forget to store them again. If estimates have been saved, do not forget to save them again.

Notes are most useful when you intend to save estimation results in a file; see [R] **estimates save**. For instance, after fitting a model, you might type

```
. estimates note:  I think these are final
. estimates save lock2
```

and then, later when going through your files, you could type

```
. estimates use lock2
. estimates notes
  1.  I think these are final
```

Up to 9,999 notes can be attached to estimation results. If estimation results are important, we recommend that you add a note identifying the `.dta` dataset you used. The best way to do that is to type

```
. estimates notes:  file `c(filename)'
```

because `` `c(filename)' `` will expand to include not just the name of the file but also its full path; see [P] **creturn**.

If estimation results took a long time to estimate—say, they were produced by `asmprobit` or `gllamm` (see [R] **asmprobit** and http://www.gllamm.org)—it is also a good idea to add a data signature. A data signature takes less time to compute than reestimation when you need proof that you really have the right dataset. The easy way to do that is to type

```
. datasignature
  74:12(71728):3831085005:1395876116
. estimates notes:  datasignature reports 'r(datasignature)'
```

Now when you ask to see the notes, you will see

```
. estimates notes
  1.  I think these are final
  2.  file C:\project\one\pat4.dta
  3.  datasignature reports 74:12(71728):3831085005:1395876116
```

See [D] **datasignature**.

Notes need not be positive. You might set a note to be, "I need to check that age is defined correctly."

▷ Example 1

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ if foreign
  (output omitted)
. estimates notes: file 'c(filename)'
. datasignature
  74:12(71728):3831085005:1395876116
. estimates notes: datasignature report 'r(datasignature)'
. estimates save foreign
file foreign.ster saved
. estimates notes list in 1/2
    1.  file http://www.stata-press.com/data/r12/auto.dta
    2.  datasignature report 74:12(71728):3831085005:1395876116
. estimates notes drop in 2
  (1 note dropped)
. estimates notes
    1.  file http://www.stata-press.com/data/r12/auto.dta
```

◁

Methods and formulas

`estimates notes` is implemented as an ado-file.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates replay — Redisplay estimation results

Syntax

```
estimates replay
```

```
estimates replay namelist
```

where *namelist* is a name, a list of names, `_all`, or `*`. A name may be `.`, meaning the current (active) estimates. `_all` and `*` mean the same thing.

Menu

Statistics > Postestimation > Manage estimation results > Redisplay estimation output

Description

`estimates replay` redisplays the current (active) estimation results, just as typing the name of the estimation command would do.

`estimates replay` *namelist* redisplays each specified estimation result. The active estimation results are left unchanged.

Remarks

In the example that follows, we fit a model two different ways, store the results, use `estimates for` to perform the same test on both of them, and then replay the results:

▷ Example 1

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. gen fwgt = foreign*weight
. gen dwgt = !foreign*weight
. gen gpm = 1/mpg
. regress gpm fwgt dwgt displ foreign
  (output omitted)
. estimates store reg
. qreg gpm fwgt dwgt displ foreign
  (output omitted)
. estimates store qreg
. estimates for reg qreg: test fwgt==dwgt
```

```
-------------------------------------------------------------------------------
Model reg
-------------------------------------------------------------------------------

 ( 1)  fwgt - dwgt = 0

       F(  1,    69) =    4.87
            Prob > F =    0.0307
```

```
Model qreg
------------------------------------------------------------------------------

 ( 1)  fwgt - dwgt = 0
       F(  1,    69) =    0.07
            Prob > F =    0.7937

. estimates replay
------------------------------------------------------------------------------
Model qreg
------------------------------------------------------------------------------

Methods and formulas

`estimates replay` is implemented as an ado-file.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates save — Save and use estimation results

Syntax

```
estimates save filename [, append replace]

estimates use filename [, number(#)]

estimates esample: [varlist] [if] [in] [weight]
    [, replace stringvars(varlist) zeroweight]

estimates esample
```

Menu

estimates save

Statistics > Postestimation > Manage estimation results > Save to disk

estimates use

Statistics > Postestimation > Manage estimation results > Load from disk

Description

`estimates save` *filename* saves the current (active) estimation results in *filename*.

`estimates use` *filename* loads the results saved in *filename* into the current (active) estimation results.

In both cases, if *filename* is specified without an extension, `.ster` is assumed.

`estimates esample:` (note the colon) resets `e(sample)`. After `estimates use` *filename*, `e(sample)` is set to contain 0, meaning that none of the observations currently in memory was used in obtaining the estimates.

`estimates esample` (without a colon) displays how `e(sample)` is currently set.

Options

`append`, used with `estimates save`, specifies that results be appended to an existing file. If the file does not already exist, a new file is created.

`replace`, used with `estimates save`, specifies that *filename* can be replaced if it already exists.

`number(#)`, used with `estimates use`, specifies that the #th set of estimation results from *filename* be loaded. This assumes that multiple sets of estimation results have been saved in *filename* by `estimates save, append`. The default is `number(1)`.

`replace`, used with `estimates esample:`, specifies that `e(sample)` can be replaced even if it is already set.

`stringvars(`*varlist*`)`, used with `estimates esample:`, specifies string variables. Observations containing variables that contain `""` will be omitted from `e(sample)`.

`zeroweight`, used with `estimates esample:`, specifies that observations with zero weights are to be included in `e(sample)`.

Remarks

See [R] **estimates** for an overview of the `estimates` commands.

For a description of `estimates save` and `estimates use`, see *Saving and using estimation results* in [R] **estimates**.

The rest of this entry concerns `e(sample)`.

Remarks are presented under the following headings:

Setting e(sample)
Resetting e(sample)
Determining who set e(sample)

Setting e(sample)

After `estimates use` *filename*, the situation is nearly identical to what it was immediately after you fit the model. The one difference is that `e(sample)` is set to 0.

`e(sample)` is Stata's function to mark which observations among those currently in memory were used in producing the estimates. For instance, you might type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ if foreign
  (output omitted)
. summarize mpg if e(sample)
  (output omitted)
```

and `summarize` would report the summary statistics for the observations `regress` in fact used, which would exclude not only observations for which `foreign` = 0 but also any observations for which `mpg`, `weight`, or `displ` was missing.

If you saved the above estimation results and then reloaded them, however, `summarize mpg if e(sample)` would produce

```
. summarize mpg if e(sample)
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
         mpg |         0
```

Stata thinks that none of these observations was used in producing the estimates currently loaded.

What else could Stata think? When you `estimates use` *filename*, you do not have to have the original data in memory. Even if you do have data in memory that look like the original data, it might not be. Setting `e(sample)` to 0 is the safe thing to do. There are some postestimation statistics, for instance, that are appropriate only when calculated on the estimation sample. Setting `e(sample)` to 0 ensures that, should you ask for one of them, you will get back a null result.

We recommend that you leave e(sample) set to 0. But what if you really need to calculate that postestimation statistic? Well, you can get it, but you are going to take responsibility for setting e(sample) correctly. Here we just happen to know that all the foreign observations were used, so we can type

```
. estimates esample:  if foreign
```

If all the observations had been used, we could simply type

```
. estimates esample:
```

The safe thing to do, however, is to look at the estimation command—estimates describe will show it to you—and then type

```
. estimates esample:  mpg weight displ if foreign
```

Resetting e(sample)

estimates esample: will allow you to not only set but also reset e(sample). If e(sample) has already been set (say that you just fit the model) and you try to set it, you will see

```
. estimates esample:  mpg weight displ if foreign
no; e(sample) already set
r(322);
```

Here you can specify the replace option:

```
. estimates esample:  mpg weight displ if foreign, replace
```

We do not recommend resetting e(sample), but the situation can arise where you need to. Imagine that you estimates use *filename*, you set e(sample), and then you realize that you set it wrong. Here you would want to reset it.

Determining who set e(sample)

estimates esample without a colon will report whether and how e(sample) was set. You might see

```
. estimates esample
  e(sample) set by estimation command
```

or

```
. estimates esample
  e(sample) set by user
```

or

```
. estimates esample
  e(sample) not set (0 assumed)
```

Saved results

estimates esample without the colon saves macro r(who), which will contain cmd, user, or zero'd.

Methods and formulas

`estimates save`, `estimates use`, `estimates esample:`, and `estimates esample` are implemented as ado-files.

[R] **estimates** — Save and manipulate estimation results

Title

estimates stats — Model statistics

Syntax

`estimates stats` [*namelist*] [`, n(#)`]

where *namelist* is a name, a list of names, `_all`, or `*`. A name may be `.`, meaning the current (active) estimates. `_all` and `*` mean the same thing.

Menu

Statistics > Postestimation > Manage estimation results > Table of fit statistics

Description

`estimates stats` reports model-selection statistics, including the Akaike information criterion (AIC) and the Bayesian information criterion (BIC). These measures are appropriate for maximum likelihood models.

If `estimates stats` is used for a non–likelihood-based model, such as `qreg`, missing values are reported.

Option

`n(#)` specifies the N to be used in calculating BIC; see [R] **BIC note**.

Remarks

If you type `estimates stats` without arguments, a table for the most recent estimation results will be shown:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. logistic foreign mpg weight displ
  (output omitted)
. estimates stats
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
.	74	-45.03321	-20.59083	4	49.18167	58.39793

Note: N=Obs used in calculating BIC; see **[R] BIC note**

Regarding the note at the bottom of the table, N is an ingredient in the calculation of BIC; see [R] **BIC note**. The note changes if you specify the `n()` option, which tells `estimates stats` what N to use. $N =$ `Obs` is the default.

Regarding the table itself, `ll(null)` is the log likelihood for the constant-only model, `ll(model)` is the log likelihood for the model, `df` is the number of degrees of freedom, and `AIC` and `BIC` are the Akaike and Bayesian information criteria.

Models with smaller values of an information criterion are considered preferable.

`estimates stats` can compare estimation results:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. logistic foreign mpg weight displ
  (output omitted)
. estimates store full
. logistic foreign mpg weight
  (output omitted)
. estimates store sub
. estimates stats full sub
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
full	74	-45.03321	-20.59083	4	49.18167	58.39793
sub	74	-45.03321	-27.17516	3	60.35031	67.26251

Note: N=Obs used in calculating BIC; see **[R] BIC note**

Saved results

`estimates stats` saves the following in `r()`:

Matrices

`r(S)` matrix with 6 columns (N, ll0, ll, df, AIC, and BIC) and rows corresponding to models in table

Methods and formulas

`estimates stats` is implemented as an ado-file.

See [R] **BIC note**.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates store — Store and restore estimation results

Syntax

```
estimates store name [, nocopy]

estimates restore name

estimates query

estimates dir [namelist]

estimates drop namelist

estimates clear
```

where *namelist* is a name, a list of names, `_all`, or `*`. `_all` and `*` mean the same thing.

Menu

estimates store

Statistics > Postestimation > Manage estimation results > Store in memory

estimates restore

Statistics > Postestimation > Manage estimation results > Restore from memory

estimates dir

Statistics > Postestimation > Manage estimation results > List results stored in memory

estimates drop

Statistics > Postestimation > Manage estimation results > Drop from memory

Description

`estimates store` *name* saves the current (active) estimation results under the name *name*.

`estimates restore` *name* loads the results saved under *name* into the current (active) estimation results.

`estimates query` tells you whether the current (active) estimates have been stored and, if so, the name.

`estimates dir` displays a list of the stored estimates.

`estimates drop` *namelist* drops the specified stored estimation results.

`estimates clear` drops all stored estimation results.

`estimates clear`, `estimates drop _all`, and `estimates drop *` do the same thing. `estimates drop` and `estimates clear` do not eliminate the current (active) estimation results.

Option

`nocopy`, used with `estimates store`, specifies that the current (active) estimation results are to be moved into *name* rather than copied. Typing

```
. estimates store hold, nocopy
```

is the same as typing

```
. estimates store hold
. ereturn clear
```

except that the former is faster. The `nocopy` option is sometimes used by programmers.

Remarks

`estimates store` stores estimation results in memory so that you can access them later.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ
  (output omitted)
. estimates store myreg
. ... you do other things, including fitting other models ...
. estimates restore myreg
. regress
  (same output shown again)
```

After `estimates restore myreg`, things are once again just as they were, estimationwise, just after you typed `regress mpg weight displ`.

`estimates store` stores results in memory. When you exit Stata, those stored results vanish. If you wish to make a permanent copy of your estimation results, see [R] **estimates save**.

The purpose of making copies in memory is 1) so that you can quickly switch between them and 2) so that you can make tables comparing estimation results. Concerning the latter, see [R] **estimates table** and [R] **estimates stats**.

Saved results

`estimates dir` saves the following in `r()`:

Macros
`r(names)` names of stored results

Methods and formulas

`estimates store`, `estimates restore`, `estimates query`, `estimates dir`, `estimates drop`, and `estimates clear` are implemented as ado-files.

Title

estimates table — Compare estimation results

Syntax

`estimates table` [*namelist*] [`,` *options*]

where *namelist* is a name, a list of names, `_all`, or `*`. A name may be `.`, meaning the current (active) estimates. `_all` and `*` mean the same thing.

options	Description
Main	
`stats(`*scalarlist*`)`	report *scalarlist* in table
`star[ (`*#1 #2 #3*`) ]`	use stars to denote significance levels
Options	
`keep(`*coeflist*`)`	report coefficients in order specified
`drop(`*coeflist*`)`	omit specified coefficients from table
`equations(`*matchlist*`)`	match equations of models as specified
Numerical formats	
`b[ (%`*fmt*`) ]`	how to format coefficients, which are always reported
`se[ (%`*fmt*`) ]`	report standard errors and use optional format
`t[ (%`*fmt*`) ]`	report t or z and use optional format
`p[ (%`*fmt*`) ]`	report p-values and use optional format
`stfmt(%`*fmt*`)`	how to format scalar statistics
General format	
`varwidth(#)`	use # characters to display variable names and statistics
`modelwidth(#)`	use # characters to display model names
`eform`	display coefficients in exponentiated form
`label`	display variable labels rather than variable names
`newpanel`	display statistics in separate table from coefficients
`style(oneline)`	put vertical line after variable names; the default
`style(columns)`	put vertical line separating every column
`style(noline)`	suppress all vertical lines
`coded`	display compact table
Reporting	
display_options	control row spacing and display of omitted variables and base and empty cells
`title(`*string*`)`	title for table

`title()` does not appear in the dialog box.

where

- A *scalarlist* is a list of any or all of the names of scalars stored in `e()`, plus `aic`, `bic`, and `rank`.
- *#1 #2 #3* are three numbers such as `.05 .01 .001`.
- A *coeflist* is a list of coefficient names, each name of which may be simple (for example, `price`), an equation name followed by a colon (for example, `mean:`), or a full name (for example, `mean:price`). Names are separated by blanks.
- A *matchlist* specifies how equations from different estimation results are to be matched. If you need to specify a *matchlist*, the solution is usually `1`, as in `equations(1)`. The full syntax is

$$matchlist \;:=\; term \;\left[\, \texttt{,}\; term \;\ldots\; \right]$$

$$term \;:=\; \left[\, eqname \;\texttt{=}\, \right]\; \#\texttt{:}\#\ldots\texttt{:}\#$$
$$\left[\, eqname \;\texttt{=}\, \right]\; \#$$

  See `equations()` under *Options* below.

Menu

Statistics > Postestimation > Manage estimation results > Table of estimation results

Description

`estimates table` displays a table of coefficients and statistics for one or more sets of estimation results.

Options

Main

`stats(`*scalarlist*`)` specifies one or more scalar statistics to be displayed in the table. *scalarlist* may contain

`aic`	Akaike's information criterion
`bic`	Schwarz's Bayesian information criterion
`rank`	rank of `e(V)` (# of free parameters in model)

along with the names of any scalars stored in `e()`. The specified statistics do not have to be available for all estimation results being displayed.

For example, `stats(N ll chi2 aic)` specifies that `e(N)`, `e(ll)`, `e(chi2)`, and AIC be included. In Stata, `e(N)` records the number of observations; `e(ll)`, the log likelihood; and `e(chi2)`, the chi-squared test that all coefficients in the first equation of the model are equal to zero.

`star` and `star(`*#1 #2 #3*`)` specify that stars (asterisks) are to be used to mark significance. The second syntax specifies the significance levels for one, two, and three stars. If you specify simply `star`, that is equivalent to specifying `star(.05 .01 .001)`, which means one star (*) if $p < 0.05$, two stars (**) if $p < 0.01$, and three stars (***) if $p < 0.001$.

The `star` and `star()` options may not be combined with `se`, `t`, or `p` option.

Options

`keep(`*coeflist*`)` and `drop(`*coeflist*`)` are alternatives; they specify coefficients to be included or omitted from the table. The default is to display all coefficients.

If `keep()` is specified, it specifies not only the coefficients to be included but also the order in which they appear.

A *coeflist* is a list of coefficient names, each name of which may be simple (for example, `price`), an equation name followed by a colon (for example, `mean:`), or a full name (for example, `mean:price`). Names are separated from each other by blanks.

When full names are not specified, all coefficients that match the partial specification are included. For instance, `drop(_cons)` would omit `_cons` for all equations.

`equations(`*matchlist*`)` specifies how the equations of the models in *namelist* are to be matched. The default is to match equations by name. Matching by name usually works well when all results were fit by the same estimation command. When you are comparing results from different estimation commands, however, specifying `equations()` may be necessary.

The most common usage is `equations(1)`, which indicates that all first equations are to be matched into one equation named `#1`.

matchlist has the syntax

term [, *term* ...]

where *term* is

[*eqname* =] #:#...:# (syntax 1)

[*eqname* =] # (syntax 2)

In syntax 1, each # is a number or a period (`.`). If a number, it specifies the position of the equation in the corresponding model; `1:3:1` would indicate that equation 1 in the first model matches equation 3 in the second, which matches equation 1 in the third. A period indicates that there is no corresponding equation in the model; `1:.:1` indicates that equation 1 in the first matches equation 1 in the third.

In syntax 2, you specify just one number, say, `1` or `2`, and that is shorthand for `1:1...:1` or `2:2...:2`, meaning that equation 1 matches across all models specified or that equation 2 matches across all models specified.

Now that you can specify a *term*, you can put that together into a *matchlist* by separating one term from the other by commas. In what follows, we will assume that three names were specified,

```
. estimates table alpha beta gamma, ...
```

`equations(1)` is equivalent to `equations(1:1:1)`; we would be saying that the first equations match across the board.

`equations(1:.:1)` would specify that equation 1 matches in models `alpha` and `gamma` but that there is nothing corresponding in model `beta`.

`equations(1,2)` is equivalent to `equations(1:1:1, 2:2:2)`. We would be saying that the first equations match across the board and so do the second equations.

`equations(1, 2:.:2)` would specify that the first equations match across the board, that the second equations match for models `alpha` and `gamma`, and that there is nothing equivalent to equation 2 in model `beta`.

If `equations()` is specified, equations not matched by position are matched by name.

Numerical formats

`b(%`*fmt*`)` specifies how the coefficients are to be displayed. You might specify `b(%9.2f)` to make decimal points line up. There is also a `b` option, which specifies that coefficients are to be displayed, but that is just included for consistency with the `se`, `t`, and `p` options. Coefficients are always displayed.

`se`, `t`, and `p` specify that standard errors, t or z statistics, and significance levels are to be displayed. The default is not to display them. `se(%`*fmt*`)`, `t(%`*fmt*`)`, and `p(%`*fmt*`)` specify that each is to be displayed and specifies the display format to be used to format them.

`stfmt(%`*fmt*`)` specifies the format for displaying the scalar statistics included by the `stats()` option.

General format

`varwidth(#)` specifies the number of character positions used to display the names of the variables and statistics. The default is 12.

`modelwidth(#)` specifies the number of character positions used to display the names of the models. The default is 12.

`eform` displays coefficients in exponentiated form. For each coefficient, $\exp(\beta)$ rather than β is displayed, and standard errors are transformed appropriately. Display of the intercept, if any, is suppressed.

`label` specifies that variable labels be displayed instead of variable names.

`newpanel` specifies that the statistics be displayed in a table separated by a blank line from the table with coefficients rather than in the style of another equation in the table of coefficients.

`style(`*stylespec*`)` specifies the style of the coefficient table.

`style(oneline)` specifies that a vertical line be displayed after the variables but not between the models. This is the default.

`style(columns)` specifies that vertical lines be displayed after each column.

`style(noline)` specifies that no vertical lines be displayed.

`coded` specifies that a compact table be displayed. This format is especially useful for comparing variables that are included in a large collection of models.

Reporting

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, and `allbaselevels`; see [R] **estimation options**.

The following option is available with `estimates table` but is not shown in the dialog box:

`title(`*string*`)` specifies the title to appear above the table.

Remarks

If you type `estimates table` without arguments, a table of the most recent estimation results will be shown:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ
  (output omitted)
```

```
. estimates table
```

Variable	active
weight	-.00656711
displacement	.00528078
_cons	40.084522

The real use of `estimates table`, however, is for comparing estimation results, and that requires using it after `estimates store`:

```
. regress mpg weight displ
  (output omitted)
. estimates store base
. regress mpg weight displ foreign
  (output omitted)
. estimates store alt
. qreg mpg weight displ foreign
  (output omitted)
. estimates store qreg
. estimates table base alt qreg, stats(r2)
```

Variable	base	alt	qreg
weight	-.00656711	-.00677449	-.00595056
displacement	.00528078	.00192865	.00018552
foreign		-1.6006312	-2.1326004
_cons	40.084522	41.847949	39.213348
r2	.6529307	.66287957	

Saved results

`estimates table` saves the following in `r()`:

Macros

`r(names)` names of results used

Matrices

`r(coef)` matrix M: $n \times 2{*}m$
$M[i, 2j-1]$ = ith parameter estimate for model j;
$M[i, 2j]$ = variance of $M[i, 2j-1]$; i=1,...,n; j=1,...,m

`r(stats)` matrix S: $k \times m$ (if option `stats()` specified)
$S[i, j]$ = ith statistic for model j; i=1,...,k; j=1,...,m

Methods and formulas

`estimates table` is implemented as an ado-file.

Reference

Weiss, M. 2010. Stata tip 90: Displaying partial results. *Stata Journal* 10: 500–502.

Also see

[R] **estimates** — Save and manipulate estimation results

Title

estimates title — Set title for estimation results

Syntax

```
estimates title: [text]

estimates title
```

Menu

Statistics > Postestimation > Manage estimation results > Title/retitle results

Description

`estimates title:` (note the colon) sets or clears the title for the current estimation results. The title is used by `estimates table` and `estimates stats` (see [R] **estimates table** and [R] **estimates stats**).

`estimates title` without the colon displays the current title.

Remarks

After setting the title, if estimates have been stored, do not forget to store them again:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg gear turn
  (output omitted)
. estimates store reg
```

Now let's add a title:

```
. estimates title: "My regression"
. estimates store reg
```

Methods and formulas

`estimates title:` and `estimates title` are implemented as ado-files.

[R] **estimates** — Save and manipulate estimation results

Title

estimation options — Estimation options

Description

This entry describes the options common to many estimation commands. Not all the options documented below work with all estimation commands. See the documentation for the particular estimation command; if an option is listed there, it is applicable.

Options

Model

`noconstant` suppresses the constant term (intercept) in the model.

`offset(`*varname*`)` specifies that *varname* be included in the model with the coefficient constrained to be 1.

`exposure(`*varname*`)` specifies a variable that reflects the amount of exposure over which the *depvar* events were observed for each observation; ln(*varname*) with coefficient constrained to be 1 is entered into the log-link function.

`constraints(`*numlist* | *matname*`)` specifies the linear constraints to be applied during estimation. The default is to perform unconstrained estimation. See [R] **reg3** for the use of constraints in multiple-equation contexts.

`constraints(`*numlist*`)` specifies the constraints by number after they have been defined by using the `constraint` command; see [R] **constraint**. Some commands (for example, `slogit`) allow only `constraints(`*numlist*`)`.

`constraints(`*matname*`)` specifies a matrix containing the constraints; see [P] **makecns**.

`constraints(`*clist*`)` is used by some estimation commands, such as `mlogit`, where *clist* has the form #[-#] [, #[-#] ...].

`collinear` specifies that the estimation command not omit collinear variables. Usually, there is no reason to leave collinear variables in place, and, in fact, doing so usually causes the estimation to fail because of the matrix singularity caused by the collinearity. However, with certain models, the variables may be collinear, yet the model is fully identified because of constraints or other features of the model. In such cases, using the `collinear` option allows the estimation to take place, leaving the equations with collinear variables intact. This option is seldom used.

`force` specifies that estimation be forced even though the time variable is not equally spaced. This is relevant only for correlation structures that require knowledge of the time variable. These correlation structures require that observations be equally spaced so that calculations based on lags correspond to a constant time change. If you specify a time variable indicating that observations are not equally spaced, the (time dependent) model will not be fit. If you also specify `force`, the model will be fit, and it will be assumed that the lags based on the data ordered by the time variable are appropriate.

Correlation

`corr(`*correlation*`)` specifies the within-group correlation structure; the default corresponds to the equal-correlation model, `corr(exchangeable)`.

When you specify a correlation structure that requires a lag, you indicate the lag after the structure's name with or without a blank; for example, `corr(ar 1)` or `corr(ar1)`.

If you specify the fixed correlation structure, you specify the name of the matrix containing the assumed correlations following the word `fixed`, for example, `corr(fixed myr)`.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`noskip` specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test of all the parameters in the regression equation being zero (except the constant). For many models, this option can substantially increase estimation time.

`nocnsreport` specifies that no constraints be reported. The default is to display user-specified constraints above the coefficient table.

`noomitted` specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as "(omitted)".

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`noemptycells` specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as "(empty)".

`baselevels` and `allbaselevels` control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.

`baselevels` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.

`allbaselevels` specifies that all base levels of factor variables and interactions be reported.

`cformat(%`*fmt*`)` specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

`pformat(%`*fmt*`)` specifies how to format p-values in the coefficient table.

`sformat(%`*fmt*`)` specifies how to format test statistics in the coefficient table.

`nolstretch` specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the coefficient table up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

Integration

`intmethod(`*intmethod*`)` specifies the integration method to be used for the random-effects model. It accepts one of three arguments: `mvaghermite`, the default, performs mean and variance adaptive Gauss–Hermite quadrature first on every and then on alternate iterations; `aghermite` performs mode and curvature adaptive Gauss–Hermite quadrature on the first iteration only; `ghermite` performs nonadaptive Gauss–Hermite quadrature.

`intpoints(#)` specifies the number of integration points to use for integration by quadrature. The default is `intpoints(12)`; the maximum is `intpoints(195)`. Increasing this value improves the accuracy but also increases computation time. Computation time is roughly proportional to its value.

The following option is not shown in the dialog box:

`coeflegend` specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

Also see

[U] **20 Estimation and postestimation commands**

Title

exit — Exit Stata

Syntax

```
exit [, clear]
```

Description

Typing `exit` causes Stata to stop processing and return control to the operating system. If the dataset in memory has changed since the last `save` command, you must specify the `clear` option before Stata will let you exit.

`exit` may also be used for exiting do-files or programs; see [P] **exit**.

Stata for Windows users may also exit Stata by clicking on the **Close** button or by pressing *Alt+F4*.

Stata for Mac users may also exit Stata by pressing *Command+Q*.

Stata(GUI) users may also exit Stata by clicking on the **Close** button.

Option

`clear` permits you to `exit`, even if the current dataset has not been `saved`.

Remarks

Type `exit` to leave Stata and return to the operating system. If the dataset in memory has changed since the last time it was saved, however, Stata will refuse. At that point, you can either `save` the dataset and then type `exit`, or type `exit, clear`:

```
. exit
no; data in memory would be lost
r(4);
. exit, clear
```

Also see

[P] **exit** — Exit from a program or do-file

Title

exlogistic — Exact logistic regression

Syntax

`exlogistic` *depvar indepvars* [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`condvars(`*varlist*`)`	condition on variables in *varlist*
`group(`*varname*`)`	groups/strata are stratified by unique values of *varname*
`binomial(`*varname*`|#)`	data are in binomial form and the number of trials is contained in *varname* or in #
`estconstant`	estimate constant term; do not condition on the number of successes
`noconstant`	suppress constant term
Terms	
`terms(`*termsdef*`)`	terms definition
Options	
`memory(#[b|k|m|g])`	set limit on memory usage; default is `memory(10m)`
`saving(`*filename*`)`	save the joint conditional distribution to *filename*

Statistics > Exact statistics > Exact logistic regression

Description

`exlogistic` fits an exact logistic regression model of *depvar* on *indepvars*.

`exlogistic` is an alternative to `logistic`, the standard maximum-likelihood–based logistic regression estimator; see [R] **logistic**. `exlogistic` produces more-accurate inference in small samples because it does not depend on asymptotic results and `exlogistic` can better deal with one-way causation, such as the case where all females are observed to have a positive outcome.

exlogistic with the group(*varname*) option is an alternative to clogit, the conditional logistic regression estimator; see [R] **clogit**. Like clogit, exlogistic conditions on the number of positive outcomes within stratum.

depvar can be specified in two ways. It can be zero/nonzero, with zero indicating failure and nonzero representing positive outcomes (successes), or if you specify the binomial(*varname* | #) option, *depvar* may contain the number of positive outcomes within each trial.

exlogistic is computationally intensive. Unlike most estimators, rather than calculating coefficients for all independent variables at once, results for each independent variable are calculated separately with the other independent variables temporarily conditioned out. You can save considerable computer time by skipping the parameter calculations for variables that are not of direct interest. Specify such variables in the condvars() option rather than among the *indepvars*; see condvars() below.

Unlike Stata's other estimation commands, you may not use test, lincom, or other postestimation commands after exlogistic. Given the method used to calculate estimates, hypothesis tests must be performed during estimation by using exlogistic's terms() option; see terms() below.

Options

Model

condvars(*varlist*) specifies variables whose parameter estimates are not of interest to you. You can save substantial computer time and memory moving such variables from *indepvars* to condvars(). Understand that you will get the same results for x1 and x3 whether you type

```
. exlogistic y x1 x2 x3 x4
```

or

```
. exlogistic y x1 x3, condvars(x2 x4)
```

group(*varname*) specifies the variable defining the strata, if any. A constant term is assumed for each stratum identified in *varname*, and the sufficient statistics for *indepvars* are conditioned on the observed number of successes within each group. This makes the model estimated equivalent to that estimated by clogit, Stata's conditional logistic regression command (see [R] **clogit**). group() may not be specified with noconstant or estconstant.

binomial(*varname* | #) indicates that the data are in binomial form and *depvar* contains the number of successes. *varname* contains the number of trials for each observation. If all observations have the same number of trials, you can instead specify the number as an integer. The number of trials must be a positive integer at least as great as the number of successes. If binomial() is not specified, the data are assumed to be Bernoulli, meaning that *depvar* equaling zero or nonzero records one failure or success.

estconstant estimates the constant term. By default, the models are assumed to have an intercept (constant), but the value of the intercept is not calculated. That is, the conditional distribution of the sufficient statistics for the *indepvars* is computed given the number of successes in *depvar*, thus conditioning out the constant term of the model. Use estconstant if you want the estimate of the intercept reported. estconstant may not be specified with group().

noconstant; see [R] **estimation options**. noconstant may not be specified with group().

Terms

`terms(`*termname* `=` *variable* ... *variable* [`,` *termname* `=` *variable* ... *variable* ...]`)` defines additional terms of the model on which you want `exlogistic` to perform joint-significance hypothesis tests. By default, `exlogistic` reports tests individually on each variable in *indepvars*. For instance, if variables `x1` and `x3` are in *indepvars*, and you want to jointly test their significance, specify `terms(t1=x1 x3)`. To also test the joint significance of `x2` and `x4`, specify `terms(t1=x1 x3, t2=x2 x4)`. Each variable can be assigned to only one term.

Joint tests are computed only for the conditional scores tests and the conditional probabilities tests. See the `test()` option below.

Options

`memory(`*#*[`b` | `k` | `m` | `g`]`)` sets a limit on the amount of memory `exlogistic` can use when computing the conditional distribution of the parameter sufficient statistics. The default is `memory(10m)`, where `m` stands for megabyte, or 1,048,576 bytes. The following are also available: `b` stands for byte; `k` stands for kilobyte, which is equal to 1,024 bytes; and `g` stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is `1m` and the maximum is `2048m` or `2g`, but do not attempt to use more memory than is available on your computer. Also see the first technical note under example 4 on counting the conditional distribution.

`saving(`*filename* [`, replace`]`)` saves the joint conditional distribution to *filename*. This distribution is conditioned on those variables specified in `condvars()`. Use `replace` to replace an existing file with *filename*. A Stata data file is created containing all the feasible values of the parameter sufficient statistics. The variable names are the same as those in *indepvars*, in addition to a variable named `_f_` containing the feasible value frequencies (sometimes referred to as the condition numbers).

Reporting

`level(#)`; see [R] **estimation options**. The `level(#)` option will not work on replay because confidence intervals are based on estimator-specific enumerations. To change the confidence level, you must refit the model.

`coef` reports the estimated coefficients rather than odds ratios (exponentiated coefficients). `coef` may be specified when the model is fit or upon replay. `coef` affects only how results are displayed and not how they are estimated.

`test(`<u>`s`</u>`ufficient` | `score` | <u>`p`</u>`robability)` reports the significance level of the observed sufficient statistics, the conditional scores tests, or the conditional probabilities tests, respectively. The default is `test(sufficient)`. If `terms()` is included in the specification, the conditional scores test and the conditional probabilities test are applied to each term providing conditional inference for several parameters simultaneously. All the statistics are computed at estimation time regardless of which is specified. Each statistic may thus also be displayed postestimation without having to refit the model; see [R] **exlogistic postestimation**.

`mue(`*varlist*`)` specifies that median unbiased estimates (MUEs) be reported for the variables in *varlist*. By default, the conditional maximum likelihood estimates (CMLEs) are reported, except for those parameters for which the CMLEs are infinite. Specify `mue(_all)` if you want MUEs for all the *indepvars*.

`midp` instructs `exlogistic` to use the mid-p-value rule when computing the MUEs, significance levels, and confidence intervals. This adjustment is for the discreteness of the distribution and halves the value of the discrete probability of the observed statistic before adding it to the p-value. The mid-p-value rule cannot be applied to MUEs whose corresponding parameter CMLE is infinite.

`nolog` prevents the display of the enumeration log. By default, the enumeration log is displayed, showing the progress of computing the conditional distribution of the sufficient statistics.

Remarks

Exact logistic regression is the estimation of the logistic model parameters by using the conditional distribution of the parameter sufficient statistics. The estimates are referred to as the conditional maximum likelihood estimates (CMLEs). This technique was first introduced by Cox and Snell (1989) as an alternative to using maximum likelihood estimation, which can perform poorly for small sample sizes. For stratified data, exact logistic regression is a small-sample alternative to conditional logistic regression. See [R] **logit**, [R] **logistic**, and [R] **clogit** to obtain maximum likelihood estimates (MLEs) for the logistic model and the conditional logistic model. For a comprehensive overview of exact logistic regression, see Mehta and Patel (1995).

Let Y_i denote a Bernoulli random variable where we observe the outcome $Y_i = y_i$, $i = 1, \ldots, n$. Associated with each independent observation is a $1 \times p$ vector of covariates, $\mathbf{x}_i$. We will denote $\pi_i = \Pr(\mathrm{Y_i} \mid \mathbf{x_i})$ and let the logit function model the relationship between Y_i and $\mathbf{x}_i$,

$$\log\left(\frac{\pi_i}{1-\pi_i}\right) = \theta + \mathbf{x}_i\boldsymbol{\beta}$$

where the constant term θ and the $p \times 1$ vector of regression parameters $\boldsymbol{\beta}$ are unknown. The probability of observing $Y_i = y_i$, $i = 1, \ldots, n$, is

$$\Pr(\mathbf{Y} = \mathbf{y}) = \prod_{i=1}^{n} \pi_i^{y_i} (1-\pi_i)^{1-y_i}$$

where $\mathbf{Y} = (Y_1, \ldots, Y_n)$ and $\mathbf{y} = (y_1, \ldots, y_n)$. The MLEs for θ and $\boldsymbol{\beta}$ maximize the log of this function.

The sufficient statistics for θ and β_j, $j = 1, \ldots, p$, are $M = \sum_{i=1}^{n} Y_i$ and $T_j = \sum_{i=1}^{n} Y_i x_{ij}$, respectively, and we observe $M = m$ and $T_j = t_j$. By default, `exlogistic` tallies the conditional distribution of $\mathbf{T} = (T_1, \ldots, T_p)$ given $M = m$. This distribution will have a size of $\binom{n}{m}$. (It would have a size of 2^n without conditioning on $M = m$.) Denote one of these vectors $\mathbf{T}^{(k)} = (t_1^{(k)}, \ldots, t_p^{(k)})$, $k = 1, \ldots, N$, with combinatorial coefficient (frequency) c_k, $\sum_{k=1}^{N} c_k = \binom{n}{m}$. For each independent variable x_j, $j = 1, \ldots, p$, we reduce the conditional distribution further by conditioning on all other observed sufficient statistics $T_l = t_l$, $l \neq j$. The conditional probability of observing $T_j = t_j$ has the form

$$\Pr(T_j = t_j \mid T_l = t_l, l \neq j, M = m) = \frac{c\, e^{t_j \beta_j}}{\sum_k c_k e^{t_j^{(k)} \beta_j}}$$

where the sum is over the subset of $\mathbf{T}$ vectors such that $(T_1^{(k)} = t_1, \ldots, T_j^{(k)} = t_j^{(k)}, \ldots, T_p^{(k)} = t_p)$ and c is the combinatorial coefficient associated with the observed $\mathbf{t}$. The CMLE for β_j maximizes the log of this function.

Specifying nuisance variables in `condvars()` will reduce the size of the conditional distribution by conditioning on their observed sufficient statistics as well as conditioning on $M = m$. This reduces the amount of memory consumed at the cost of not obtaining regression estimates for those variables specified in `condvars()`.

Inferences from MLEs rely on asymptotics, and if your sample size is small, these inferences may not be valid. On the other hand, inferences from the CMLEs are exact in the sense that they use the conditional distribution of the sufficient statistics outlined above.

For small datasets, it is common for the dependent variable to be completely determined by the data. Here the MLEs and the CMLEs are unbounded. `exlogistic` will instead compute the MUE, the regression estimate that places the observed sufficient statistic at the median of the conditional distribution.

▷ Example 1

One example presented by Mehta and Patel (1995) is data from a prospective study of perinatal infection and human immunodeficiency virus type 1 (HIV-1). We use a variation of this dataset. There was an investigation Hutto et al. (1991) into whether the blood serum levels of glycoproteins CD4 and CD8 measured in infants at 6 months of age might predict their development of HIV infection. The blood serum levels are coded as ordinal values 0, 1, and 2.

```
. use http://www.stata-press.com/data/r12/hiv1
(prospective study of perinatal infection of HIV-1)
. list
```

	hiv	cd4	cd8
1.	1	0	0
2.	0	0	0
3.	1	0	2
4.	1	1	0
5.	0	1	0
	(output omitted)		
46.	0	2	1
47.	0	2	2

We first obtain the MLEs from `logistic` so that we can compare the estimates and associated statistics with the CMLEs from `exlogistic`.

`exlogistic` produced a log showing how many records are generated as it processes each observation. The primary purpose of the log is to provide feedback because generating the distribution can be time consuming, but we also see from the last entry that the joint distribution for the sufficient statistics for `cd4` and `cd8` conditioned on the total number of successes has 326 unique values (but a size of $\binom{47}{14} = 341{,}643{,}774{,}795$).

The statistics for `logistic` are based on asymptotics: for a large sample size, each Z statistic will be approximately normally distributed (with a mean of zero and a standard deviation of one) if the associated regression parameter is zero. The question is whether a sample size of 47 is large enough.

On the other hand, the p-values computed by `exlogistic` are from the conditional distributions of the sufficient statistics for each parameter given the sufficient statistics for all other parameters. In this sense, these p-values are exact. By default, `exlogistic` reports the sufficient statistics for the regression parameters and the probability of observing a more extreme value. These are single-parameter tests for H_0: $\beta_{\text{cd4}} = 0$ and H_0: $\beta_{\text{cd8}} = 0$ versus the two-sided alternatives. The conditional scores test, located in the coefficient table header, is testing that both H_0: $\beta_{\text{cd4}} = 0$ and H_0: $\beta_{\text{cd8}} = 0$. We find these p-values to be in fair agreement with the Wald and likelihood-ratio tests from `logistic`.

The confidence intervals for `exlogistic` are computed from the exact conditional distributions. The exact confidence intervals are asymmetrical about the estimate and are wider than the normal-based confidence intervals from `logistic`.

Both estimation techniques indicate that the incidence of HIV infection decreases with increasing CD4 blood serum levels and increases with increasing CD8 blood serum levels. The constant term is missing from the exact logistic coefficient table because we conditioned out its observed sufficient statistic when tallying the joint distribution of the sufficient statistics for the `cd4` and `cd8` parameters.

The `test()` option provides two other test statistics used in exact logistic: the conditional scores test, `test(score)`, and the conditional probabilities test, `test(probability)`. For comparison, we display the individual parameter conditional scores tests.

```
. exlogistic, test(score) coef
Exact logistic regression                       Number of obs =         47
                                                Model score   =   13.34655
                                                Pr >= score   =     0.0006
```

hiv	Coef.	Score	Pr>=Score	[95% Conf.	Interval]
cd4	-2.387632	12.88022	0.0003	-4.699633	-.8221807
cd8	1.592366	4.604816	0.0410	-.0137905	3.907876

For the probabilities test, the probability statistic is computed from (1) in *Methods and formulas* with $\beta = 0$. For this example, the significance of the probabilities tests matches the scores tests so they are not displayed here.

◁

❑ Technical note

Typically, the value of θ, the constant term, is of little interest, as well as perhaps some of the parameters in β, but we need to include all parameters in the model to correctly specify it. By conditioning out the nuisance parameters, we can reduce the size of the joint conditional distribution that is used to estimate the regression parameters of interest. The `condvars()` option allows you to specify a *varlist* of nuisance variables. By default, `exlogistic` conditions on the sufficient statistic of θ, which is the number of successes. You can save computation time and computer memory by using the `condvars()` option because infeasible values of the sufficient statistics associated with the variables in `condvars()` can be dropped from consideration before all n observations are processed.

Specifying some of your independent variables in `condvars()` will not change the estimated regression coefficients of the remaining independent variables. For instance, in example 1, if we instead type

```
. exlogistic hiv cd4, condvars(cd8) coef
```

the regression coefficient for `cd4` (as well as all associated inference) will be identical.

One reason to have multiple variables in *indepvars* is to make conditional inference of several parameters simultaneously by using the `terms()` option. If you do not wish to test several parameters simultaneously, it may be more efficient to obtain estimates for individual variables by calling `exlogistic` multiple times with one variable in *indepvars* and all other variables listed in `condvars()`. The estimates will be the same as those with all variables in *indepvars*.

❑

❑ Technical note

If you fit a `clogit` (see [R] **clogit**) model to the HIV data from example 1, you will find that the estimates differ from those with `exlogistic`. (To fit the `clogit` model, you will have to create a group variable that includes all observations.) The regression estimates will be different because `clogit` conditions on the constant term only, whereas the estimates from `exlogistic` condition on the sufficient statistic of the other regression parameter as well as the constant term.

❑

▷ Example 2

The HIV data presented in table IV of Mehta and Patel (1995) are in a binomial form, where the variable `hiv` contains the HIV cases that tested positive and the variable `n` contains the number of individuals with the same CD4 and CD8 levels, the binomial number-of-trials parameter. Here *depvar* is `hiv`, and we use the `binomial(n)` option to identify the number-of-trials variable.

```
. use http://www.stata-press.com/data/r12/hiv_n
(prospective study of perinatal infection of HIV-1; binomial form)
. list
```

	cd4	cd8	hiv	n
1.	0	2	1	1
2.	1	2	2	2
3.	0	0	4	7
4.	1	1	4	12
5.	2	2	1	3
6.	1	0	2	7
7.	2	0	0	2
8.	2	1	0	13

Further, the `cd4` and `cd8` variables of the `hiv` dataset are actually factor variables, where each has the ordered levels of $(0, 1, 2)$. Another approach to the analysis is to use indicator variables, and following Mehta and Patel (1995), we used a 0–1 coding scheme that will give us the odds ratio of level 0 versus 2 and level 1 versus 2.

Here we used `terms()` to specify two terms in the model, `cd4` and `cd8`, that make up the `cd4` and `cd8` indicator variables. By doing so, we obtained a conditional probabilities test for `cd4`, simultaneously testing both `cd4_0` and `cd4_1`, and for `cd8`, simultaneously testing both `cd8_0` and `cd8_1`. The significance levels for the two terms are 0.0055 and 0.0323, respectively.

This example also illustrates instances where the dependent variable is completely determined by the independent variables and CMLEs are infinite. If we try to obtain MLEs, `logistic` will drop each variable and then terminate with a no-data error, error number 2000.

```

In the previous example, `exlogistic` generated the joint conditional distribution of $T_{\mathrm{cd4\_0}}$, $T_{\mathrm{cd4\_1}}$, $T_{\mathrm{cd8\_0}}$, and $T_{\mathrm{cd8\_1}}$ given $M = 14$ (the number of individuals that tested positive), and for reference, we listed the observed sufficient statistics that are stored in the matrix `e(sufficient)`. Below we take that distribution and further condition on $T_{\mathrm{cd4\_1}} = 8$, $T_{\mathrm{cd8\_0}} = 6$, and $T_{\mathrm{cd8\_1}} = 4$, giving the conditional distribution of $T_{\mathrm{cd4\_0}}$. Here we see that the observed sufficient statistic $T_{\mathrm{cd4\_0}} = 5$ is last in the sorted listing or, equivalently, $T_{\mathrm{cd4\_0}}$ is at the domain boundary of the conditional probability distribution. When this occurs, the conditional probability distribution is monotonically increasing in $\beta_{\mathrm{cd4\_0}}$ and a maximum does not exist.

```
. use dist, clear
. keep if cd4_1==8 & cd8_0==6 & cd8_1==4
(4139 observations deleted)
. list, sep(0)
```

	_f_	cd4_0	cd4_1	cd8_0	cd8_1
1.	1668667	0	8	6	4
2.	18945542	1	8	6	4
3.	55801053	2	8	6	4
4.	55867350	3	8	6	4
5.	17423175	4	8	6	4
6.	1091475	5	8	6	4

When the CMLEs are infinite, the MUEs are computed (Hirji, Tsiatis, and Mehta 1989). For the `cd4_0` estimate, we compute the value $\overline{\beta}_{\mathrm{cd4\_0}}$ such that

$$\Pr(T_{\mathrm{cd4\_0}} \geq 5 \mid \beta_{\mathrm{cd4\_0}} = \overline{\beta}_{\mathrm{cd4\_0}}, T_{\mathrm{cd4\_1}} = 8, T_{\mathrm{cd8\_0}} = 6, T_{\mathrm{cd8\_1}} = 4, M = 14) = 1/2$$

using (1) in *Methods and formulas*.

The output is in agreement with example 1: there is an increase in risk of HIV infection for a CD4 blood serum level of 0 relative to a level of 2 and for a level of 1 relative to a level of 2; there is a decrease in risk of HIV infection for a CD8 blood serum level of 0 relative to a level of 2 and for a level of 1 relative to a level of 2.

We also displayed `e(n_possible)`. This is the combinatorial coefficient associated with the observed sufficient statistics. The same value is found in the `_f_` variable of the conditional distribution dataset listed above. The size of the distribution is $\binom{47}{14} = 341{,}643{,}774{,}795$. This can be verified by summing the `_f_` variable of the generated conditional distribution dataset.

▷ Example 3

One can think of exact logistic regression as a covariate-adjusted exact binomial. To demonstrate this point, we will use `exlogistic` to compute a binomial confidence interval for m successes of n trials, by fitting the constant-only model, and we will compare it with the confidence interval computed by `ci` (see [R] **ci**). We will use the `saving()` option to retain the dataset containing the feasible values for the constant term sufficient statistic, namely, the number of successes, m, given n trials and their associated combinatorial coefficients $\binom{n}{m}$, $m = 0, 1, \ldots, n$.

We use the postestimation program `estat predict` to transform the estimated constant term and its confidence bounds by using the inverse logit function, `invlogit()` (see [D] **functions**). The standard error for the estimated probability is computed using the delta method.

```
. estat predict
```

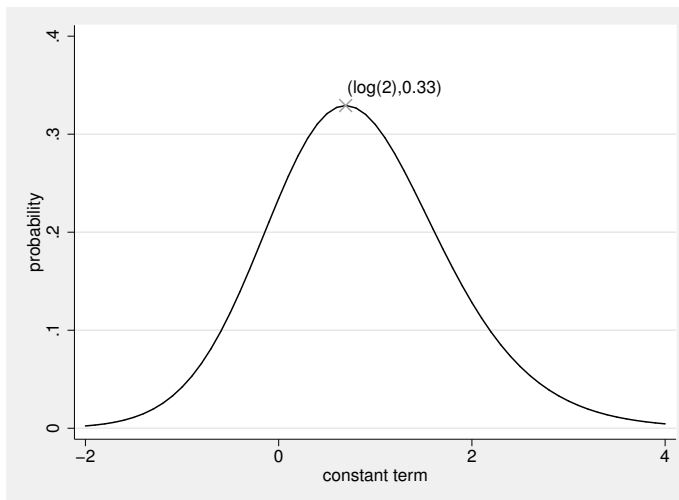
	_f_	_cons_
1.	1	0
2.	6	1
3.	15	2
4.	20	3
5.	15	4
6.	6	5
7.	1	6

Examining the listing of the generated data, the values contained in the variable `_cons_` are the feasible values of M, and the values contained in the variable `_f_` are the binomial coefficients $\binom{6}{m}$ with total $\sum_{m=0}^{6}\binom{6}{m} = 2^6 = 64$. In the coefficient table, the sufficient statistic for the constant term, labeled `Suff.`, is m = 4. This value is located at record 5 of the dataset. Therefore, the two-tailed probability of the sufficient statistic is computed as $0.6875 = 2(15 + 6 + 1)/64$.

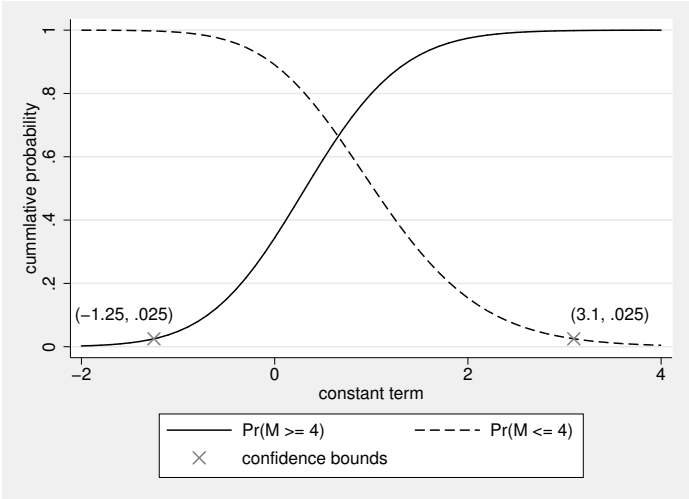
The constant term is the value of θ that maximizes the probability of observing $M = 4$; see (1) of *Methods and formulas*:

$$\Pr(M = 4|\theta) = \frac{15e^{4\alpha}}{1 + 6e^{\alpha} + 15e^{2\alpha} + 20e^{3\alpha} + 15e^{4\alpha} + 6e^{5\alpha} + e^{6\alpha}}$$

The maximum is at the value $\theta = \log 2$, which is demonstrated in the figure below.



The lower and upper confidence bounds are the values of θ such that $\Pr(M \geq 4|\theta) = 0.025$ and $\Pr(M \leq 4|\theta) = 0.025$, respectively. These probabilities are plotted in the figure below for $\theta \in [-2, 4]$.



Example 4

This example demonstrates the `group()` option, which allows the analysis of stratified data. Here the logistic model is

$$\log\left(\frac{\pi_{ik}}{1-\pi_{ik}}\right) = \theta_k + \mathbf{x}_{ki}\boldsymbol{\beta}$$

where k indexes the s strata, $k = 1, \ldots, s$, and θ_k is the strata-specific constant term whose sufficient statistic is $M_k = \sum_{i=1}^{n_k} Y_{ki}$.

Mehta and Patel (1995) use a case–control study to demonstrate this model, which is useful in comparing the estimates from `exlogistic` and `clogit`. This study was intended to determine the role of birth complications in people with schizophrenia (Garsd 1988). Siblings from seven families took part in the study, and each individual was classified as normal or schizophrenic. A birth complication index is recorded for each individual that ranges from 0, an uncomplicated birth, to 15, a very complicated birth. Some of the frequencies contained in variable `f` are greater than 1, and these count different births at different times where the individual has the same birth complications index, found in variable `BCindex`.

BCindex	.3251178	.1678981	1.94	0.053	-.0039565	.654192

Both techniques compute the same regression estimate for the `BCindex`, which might not be too surprising because both estimation techniques condition on the total number of successes in each group. The difference lies in the p-values and confidence intervals. The p-value testing $H_0: \beta_{\text{BCindex}} = 0$ is approximately 0.0167 for the exact conditional scores test and 0.053 for the asymptotic Wald test. Moreover, the exact confidence interval is asymmetric about the estimate and does not contain zero.

◁

❑ Technical note

The `memory(#)` option limits the amount of memory that `exlogistic` will consume when computing the conditional distribution of the parameter sufficient statistics. `memory()` is independent of the data maximum memory setting (see `set max_memory` in [D] **memory**), and it is possible for `exlogistic` to exceed the memory limit specified in `set max_memory` without terminating. By default, a log is provided that displays the number of enumerations (the size of the conditional distribution) after processing each observation. Typically, you will see the number of enumerations increase, and then at some point they will decrease as the multivariate shift algorithm (Hirji, Mehta, and Patel 1987) determines that some of the enumerations cannot achieve the observed sufficient statistics of the conditioning variables. When the algorithm is complete, however, it is necessary to store the conditional distribution of the parameter sufficient statistics as a dataset. It is possible, therefore, to get a memory error when the algorithm has completed if there is not enough memory to store the conditional distribution.

❑

❑ Technical note

Computing the conditional distributions and reported statistics requires data sorting and numerical comparisons. If there is at least one single-precision variable specified in the model, `exlogistic` will make comparisons with a relative precision of 2^{-5}. Otherwise, a relative precision of 2^{-11} is used. Be careful if you use `recast` to promote a single-precision variable to double precision (see [D] **recast**). You might try listing the data in full precision (maybe `%20.15g`; see [D] **format**) to make sure that this is really what you want. See [D] **data types** for information on precision of numeric storage types.

Methods and formulas

exlogistic is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Sufficient statistics
Conditional distribution and CMLE
Median unbiased estimates and exact CI
Conditional hypothesis tests
Sufficient-statistic p-value

Sufficient statistics

Let $\{Y_1, Y_2, \ldots, Y_n\}$ be a set of n independent Bernoulli random variables, each of which can realize two outcomes, $\{0, 1\}$. For each $i = 1, \ldots, n$, we observe $Y_i = y_i$, and associated with each observation is the covariate row vector of length p, $\mathbf{x}_i = (x_{i1}, \ldots, x_{ip})$. Denote $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_p)^T$ to be the column vector of regression parameters and θ to be the constant. The sufficient statistic for β_j is $T_j = \sum_{i=1}^n Y_i x_{ij}$, $j = 1, \ldots, p$, and for θ is $M = \sum_{i=1}^n Y_i$. We observe $T_j = t_j$, $t_j = \sum_{i=1}^n y_i x_{ij}$, and $M = m$, $m = \sum_{i=1}^n y_i$. The probability of observing $(Y_1 = y_1, Y_2 = y_2, \ldots, Y_n = y_n)$ is

$$\Pr(Y_1 = y_1, \ldots, Y_n = y_n \mid \boldsymbol{\beta}, \mathbf{X}) = \frac{\exp(m\theta + \mathbf{t}\boldsymbol{\beta})}{\prod_{i=1}^n \{1 + \exp(\theta + \mathbf{x}_i\boldsymbol{\beta})\}}$$

where $\mathbf{t} = (t_1, \ldots, t_p)$ and $\mathbf{X} = (\mathbf{x}_1^T, \ldots, \mathbf{x}_n^T)^T$.

The joint distribution of the sufficient statistics $\mathbf{T}$ is obtained by summing over all possible binary sequences $Y_1, \ldots, Y_n$ such that $\mathbf{T} = \mathbf{t}$ and $M = m$. This probability function is

$$\Pr(T_1 = t_1, \ldots, T_p = t_p, M = m \mid \boldsymbol{\beta}, \mathbf{X}) = \frac{c(\mathbf{t}, m)\exp(m\theta + \mathbf{t}\boldsymbol{\beta})}{\prod_{i=1}^n \{1 + \exp(\theta + \mathbf{x}_i\boldsymbol{\beta})\}}$$

where $c(\mathbf{t}, m)$ is the combinatorial coefficient of $(\mathbf{t}, m)$ or the number of distinct binary sequences $Y_1, \ldots, Y_n$ such that $\mathbf{T} = \mathbf{t}$ and $M = m$ (Cox and Snell 1989).

Conditional distribution and CMLE

Without loss of generality, we will restrict our discussion to computing the CMLE of β_1. If we condition on observing $M = m$ and $T_2 = t_2, \ldots, T_p = t_p$, the probability function of $(T_1 \mid \beta_1, T_2 = t_2, \ldots, T_p = t_p, M = m)$ is

$$\Pr(T_1 = t_1 \mid \beta_1, T_2 = t_2, \ldots, T_p = t_p, M = m) = \frac{c(\mathbf{t}, m)e^{t_1\beta_1}}{\sum_u c(u, t_2, \ldots, t_p, m)e^{u\beta_1}} \tag{1}$$

where the sum in the denominator is over all possible values of T_1 such that $M = m$ and $T_2 = t_2, \ldots, T_p = t_p$ and $c(u, t_2, \ldots, t_p, m)$ is the combinatorial coefficient of $(u, t_2, \ldots, t_p, m)$ (Cox and Snell 1989). The CMLE for β_1 is the value $\widehat{\beta}_1$ that maximizes the log of (1). This optimization task is carried out by `ml`, using the conditional frequency distribution of $(T_1 \mid T_2 = t_2, \ldots, T_p = t_p, M = m)$ as a dataset. Generating the joint conditional distribution is efficiently computed using the multivariate shift algorithm described by Hirji, Mehta, and Patel (1987).

Difficulties in computing $\widehat{\beta}_1$ arise if the observed $(T_1 = t_1, \ldots, T_p = t_p, M = m)$ lies on the boundaries of the distribution of $(T_1 \mid T_2 = t_2, \ldots, T_p = t_p, M = m)$, where the conditional probability function is monotonically increasing (or decreasing) in β_1. Here the CMLE is plus infinity if it is on the upper boundary, $\Pr(T_1 \leq t_1 \mid T_2 = t_2, \ldots, T_p = t_p, M = m) = 1$, and is minus infinity if it is on the lower boundary of the distribution, $\Pr(T_1 \geq t_1 \mid T_2 = t_2, \ldots, T_p = t_p, M = m) = 1$. This concept is demonstrated in example 2. When infinite CMLEs occur, the MUE is computed.

Median unbiased estimates and exact CI

The MUE is computed using the technique outlined by Hirji, Tsiatis, and Mehta (1989). First, we find the values of $\beta_1^{(u)}$ and $\beta_1^{(l)}$ such that

$$\begin{aligned}&\Pr(T_1 \le t_1 \mid \beta_1 = \beta_1^{(u)}, T_2 = t_2, \ldots, T_p = t_p, M = m) = \\ &\Pr(T_1 \ge t_1 \mid \beta_1 = \beta_1^{(l)}, T_2 = t_2, \ldots, T_p = t_p, M = m) = 1/2\end{aligned} \tag{2}$$

The MUE is then $\overline{\beta}_1 = \left(\beta_1^{(l)} + \beta_1^{(u)}\right)/2$. However, if T_1 is equal to the minimum of the domain of the conditional distribution, $\beta^{(l)}$ does not exist and $\overline{\beta}_1 = \beta^{(u)}$. If T_1 is equal to the maximum of the domain of the conditional distribution, $\beta^{(u)}$ does not exist and $\overline{\beta}_1 = \beta^{(l)}$.

Confidence bounds for β are computed similarly, except that we substitute $\alpha/2$ for $1/2$ in (2), where $1-\alpha$ is the confidence level. Here $\beta_1^{(l)}$ would then be the lower confidence bound and $\beta_1^{(u)}$ would be the upper confidence bound (see example 3).

Conditional hypothesis tests

To test H_0: $\beta_1 = 0$ versus H_1: $\beta_1 \neq 0$, we obtain the exact p-value from $\sum_{u\in E} f_1(u) - f_1(t_1)/2$ if the mid-p-value rule is used and $\sum_{u\in E} f_1(u)$ otherwise. Here E is a critical region, and we define $f_1(u) = \Pr(T_1 = u \mid \beta_1 = 0, T_2 = t_2, \ldots, T_p = t_p, M = m)$ for ease of notation. There are two popular ways to define the critical region: the conditional probabilities test and the conditional scores test (Mehta and Patel 1995). The critical region when using the conditional probabilities test is all values of the sufficient statistic for β_1 that have a probability less than or equal to that of the observed t_1, $E_p = \{u:\ f_1(u) \le f_1(t_1)\}$. The critical region of the conditional scores test is defined as all values of the sufficient statistic for β_1 such that its score is greater than or equal to that of t_1,

$$E_s = \left\{u:\ (u-\mu_1)^2/\sigma_1^2 \ge (t_1-\mu_1)^2/\sigma_1^2\right\}$$

Here μ_1 and σ_1^2 are the mean and variance of $(T_1 \mid \beta_1 = 0, T_2 = t_2, \ldots, T_p = t_p, M = m)$.

The score statistic is defined as

$$\left\{\frac{\partial \ell(\beta)}{\partial \beta}\right\}^2 \left[-E\left\{\frac{\partial^2 \ell(\beta)}{\partial \beta^2}\right\}\right]^{-1}$$

evaluated at H_0: $\beta = 0$, where ℓ is the log of (1). The score test simplifies to $(t - E[T|\beta])^2/\mathrm{var}(T|\beta)$ (Hirji 2006), where the mean and variance are computed from the conditional distribution of the sufficient statistic with $\beta = 0$ and t is the observed sufficient statistic.

Sufficient-statistic p-value

The p-value for testing H_0: $\beta_1 = 0$ versus the two-sided alternative when $(T_1 = t_1 | T_2 = t_2, \ldots, T_p = t_p)$ is computed as $2\times\min(p_l, p_u)$, where

$$p_l = \frac{\sum_{u\le t_1} c(u, t_2, \ldots, t_p, m)}{\sum_u c(u, t_2, \ldots, t_p, m)}$$

$$p_u = \frac{\sum_{u\ge t_1} c(u, t_2, \ldots, t_p, m)}{\sum_u c(u, t_2, \ldots, t_p, m)}$$

It is the probability of observing a more extreme T_1.

Title

exlogistic postestimation — Postestimation tools for exlogistic

Description

The following postestimation commands are of special interest after `exlogistic`:

Command	Description
`estat predict`	single-observation prediction
`estat se`	report ORs or coefficients and their asymptotic standard errors

For information about these commands, see below.

The following standard postestimation command is also available:

Command	Description
`estat summarize`	estimation sample summary

`estat summarize` is not allowed if the `binomial()` option was specified in `exlogistic`.

See [R] **estat** for details.

Special-interest postestimation commands

`estat predict` computes a predicted probability (or linear predictor), its asymptotic standard error, and its exact confidence interval for 1 observation. Predictions are carried out by estimating the constant coefficient after shifting the independent variables and conditioned variables by the values specified in the `at()` option or by their medians. Therefore, predictions must be done with the estimation sample in memory. If a different dataset is used or if the dataset is modified, then an error will result.

`estat se` reports odds ratio or coefficients and their asymptotic standard errors. The estimates are stored in the matrix `r(estimates)`.

Syntax for estat predict

`estat predict` [, *options*]

options	Description
`pr`	probability; the default
`xb`	linear effect
`at(`*atspec*`)`	use the specified values for the *indepvars* and `condvars()`
`level(#)`	set confidence level for the predicted value; default is `level(95)`
`memory(#[b|k|m|g])`	set limit on memory usage; default is `memory(10m)`
`nolog`	do not display the enumeration log

These statistics are available only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for estat predict

`pr`, the default, calculates the probability.

`xb` calculates the linear effect.

`at(`*varname* `= #` [[*varname* `= #`] [...]]`)` specifies values to use in computing the predicted value. Here *varname* is one of the independent variables, *indepvars*, or the conditioned variables, `condvars()`. The default is to use the median of each independent and conditioned variable.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`memory(#`[`b`|`k`|`m`|`g`]`)` sets a limit on the amount of memory `estat predict` can use when generating the conditional distribution of the constant parameter sufficient statistic. The default is `memory(10m)`, where `m` stands for megabyte, or 1,048,576 bytes. The following are also available: `b` stands for byte; `k` stands for kilobyte, which is equal to 1,024 bytes; and `g` stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is `1m` and the maximum is `512m` or `0.5g`, but do not attempt to use more memory than is available on your computer. Also see *Remarks* in [R] **exlogistic** for details on enumerating the conditional distribution.

`nolog` prevents the display of the enumeration log. By default, the enumeration log is displayed showing the progress of enumerating the distribution of the observed successes conditioned on the independent variables shifted by the values specified in `at()` (or by their medians). See *Methods and formulas* in [R] **exlogistic** for details of the computations.

Syntax for estat se

```
estat se [, coef]
```

Menu

Statistics > Postestimation > Reports and statistics

Option for estat se

`coef` requests that the estimated coefficients and their asymptotic standard errors be reported. The default is to report the odds ratios and their asymptotic standard errors.

Remarks

Predictions must be done using the estimation sample. This is because the prediction is really an estimated constant coefficient (the intercept) after shifting the independent variables and conditioned variables by the values specified in `at()` or by their medians. The justification for this approach can be seen by rewriting the model as

$$\log\left(\frac{\pi_i}{1-\pi_i}\right) = (\alpha + \mathbf{x}_0\boldsymbol{\beta}) + (\mathbf{x}_i - \mathbf{x}_0)\boldsymbol{\beta}$$

where $\mathbf{x}_0$ are the specified values for the *indepvars* (Mehta and Patel 1995). Because the estimation of the constant term is required, this technique is not appropriate for stratified models that used the `group()` option.

▷ Example 1

To demonstrate, we return to the example 2 in [R] **exlogistic** using data from a prospective study of perinatal infection and HIV-1. Here there was an investigation into whether the blood serum levels of CD4 and CD8 measured in infants at 6 months of age might predict their development of HIV infection. The blood serum levels are coded as ordinal values 0, 1, and 2. These data are used by Mehta and Patel (1995) as an exposition of exact logistic.

```

```

hiv	Predicted	Std. Err.	[95% Conf.	Interval]
Probability	0.0390*	N/A	0.0000	0.1962

```
(*) identifies median unbiased estimates (MUE); because an MUE
    is computed, there is no SE estimate
```

Because we did not specify values by using the `at()` option, the median values of the *indepvars* are used for the prediction. By default, medians are used instead of means because we want to use values that are observed in the dataset. If the means of the binary variables `cd4_0`–`cd8_1` were used, we would have created floating point variables in $(0, 1)$ that not only do not properly represent the indicator variables but also would be a source of computational inefficiency in generating the conditional distribution. Because the MUE is computed for the predicted value, there is no standard-error estimate.

From the example discussions in [R] **exlogistic**, the infants at highest risk are those with a CD4 level of 0 and a CD8 level of 2. Below we use the `at()` option to make a prediction at these blood serum levels.

```
. estat predict, at(cd4_0=1 cd4_1=0 cd8_0=0 cd8_1=0) nolog

Saved results

`estat predict` saves the following in `r()`:

Scalars

`r(imue)`	`1` if `r(pred)` is an MUE and `0` if a CMLE
`r(pred)`	estimated probability or the linear effect
`r(se)`	asymptotic standard error of `r(pred)`

Macros

`r(estimate)`	prediction type: `pr` or `xb`
`r(level)`	confidence level

Matrices

`r(ci)`	confidence interval
`r(x)`	*indepvars* and `condvars()` values

Methods and formulas

All postestimation commands listed above are implemented as ado-files using Mata.

Statistics > Exact statistics > Exact Poisson regression

Description

`expoisson` fits an exact Poisson regression model of *depvar* on *indepvars*. Exact Poisson regression is an alternative to standard maximum-likelihood–based Poisson regression (see [R] **poisson**) that offers more accurate inference in small samples because it does not depend on asymptotic results. For stratified data, `expoisson` is an alternative to fixed-effects Poisson regression (see `xtpoisson, fe` in [XT] **xtpoisson**); like fixed-effects Poisson regression, exact Poisson regression conditions on the number of events in each stratum.

Exact Poisson regression is computationally intensive, so if you have regressors whose parameter estimates are not of interest (that is, nuisance parameters), you should specify those variables in the `condvars()` option instead of in *indepvars*.

Options

Model

`condvars(`*varlist*`)` specifies variables whose parameter estimates are not of interest to you. You can save substantial computer time and memory by moving such variables from *indepvars* to `condvars()`. Understand that you will get the same results for `x1` and `x3` whether you type

```
. expoisson y x1 x2 x3 x4
```

or

```
. expoisson y x1 x3, condvars(x2 x4)
```

`group(`*varname*`)` specifies the variable defining the strata, if any. A constant term is assumed for each stratum identified in *varname*, and the sufficient statistics for *indepvars* are conditioned on the observed number of successes within each group (as well as other variables in the model). The group variable must be integer valued.

`exposure(`*varname*$_e$`)`, `offset(`*varname*$_o$`)`; see [R] **estimation options**.

Options

`memory(#[ b | k | m | g ])` sets a limit on the amount of memory `expoisson` can use when computing the conditional distribution of the parameter sufficient statistics. The default is `memory(25m)`, where `m` stands for megabyte, or 1,048,576 bytes. The following are also available: `b` stands for byte; `k` stands for kilobyte, which is equal to 1,024 bytes; and `g` stands for gigabyte, which is equal to 1,024 megabytes. The minimum setting allowed is `1m` and the maximum is `2048m` or `2g`, but do not attempt to use more memory than is available on your computer. Also see the first technical note under example 3 on counting the conditional distribution.

`saving(`*filename* `[ , replace ])` saves the joint conditional distribution for each independent variable specified in *indepvars*. There is one file for each variable, and it is named using the prefix *filename* with the variable name appended. For example, `saving(mydata)` with an independent variable named `X` would generate a data file named `mydata_X.dta`. Use `replace` to replace an existing file. Each file contains the conditional distribution for one of the independent variables specified in *indepvars* conditioned on all other *indepvars* and those variables specified in `condvars()`. There are two variables in each data file: the feasible sufficient statistics for the variable's parameter and their associated weights. The weights variable is named `_w_`.

Reporting

`level(#)`; see [R] **estimation options**. The `level(#)` option will not work on replay because confidence intervals are based on estimator-specific enumerations. To change the confidence level, you must refit the model.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, $\exp(\beta)$ rather than β. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`test(sufficient | score | probability)` reports the significance level of the observed sufficient statistic, the conditional scores test, or the conditional probabilities test. The default is `test(sufficient)`. All the statistics are computed at estimation time, and each statistic may be displayed postestimation; see [R] **expoisson postestimation**.

`mue(`*varlist*`)` specifies that median unbiased estimates (MUEs) be reported for the variables in *varlist*. By default, the conditional maximum likelihood estimates (CMLEs) are reported, except for those parameters for which the CMLEs are infinite. Specify `mue(_all)` if you want MUEs for all the *indepvars*.

`midp` instructs `expoisson` to use the mid-p-value rule when computing the MUEs, significance levels, and confidence intervals. This adjustment is for the discreteness of the distribution by halving the value of the discrete probability of the observed statistic before adding it to the p-value. The mid-p-value rule cannot be MUEs whose corresponding parameter CMLE is infinite.

`nolog` prevents the display of the enumeration log. By default, the enumeration log is displayed, showing the progress of computing the conditional distribution of the sufficient statistics.

Remarks

Exact Poisson regression estimates the model parameters by using the conditional distributions of the parameters' sufficient statistics, and the resulting parameter estimates are known as CMLEs. Exact Poisson regression is a small-sample alternative to the maximum-likelihood ML Poisson model. See [R] **poisson** and [XT] **xtpoisson** to obtain maximum likelihood estimates (MLEs) for the Poisson model and the fixed-effects Poisson model.

Let Y_i denote a Poisson random variable where we observe the outcome $Y_i = y_i$, $i = 1, \ldots, n$. Associated with each independent observation is a $1 \times p$ vector of covariates, $\mathbf{x}_i$. We will denote $\mu_i = E[Y_i \mid \mathbf{x}_i]$ and use the log linear model to model the relationship between Y_i and $\mathbf{x}_i$,

$$\log(\mu_i) = \theta + \mathbf{x}_i\boldsymbol{\beta}$$

where the constant term, θ, and the $p \times 1$ vector of regression parameters, $\boldsymbol{\beta}$, are unknown. The probability of observing $Y_i = y_i$, $i = 1, \ldots, n$, is

$$\Pr(\mathbf{Y} = \mathbf{y}) = \prod_{i=1}^{n} \frac{\mu_i^{y_i} e^{-\mu_i}}{y_i!}$$

where $\mathbf{Y} = (Y_1, \ldots, Y_n)$ and $\mathbf{y} = (y_1, \ldots, y_n)$. The MLEs for θ and $\boldsymbol{\beta}$ maximize the log of this function.

The sufficient statistics for θ and β_j, $j = 1, \ldots, p$, are $M = \sum_{i=1}^{n} Y_i$ and $T_j = \sum_{i=1}^{n} Y_i x_{ij}$, respectively, and we observe $M = m$ and $T_j = t_j$. `expoisson` tallies the conditional distribution for each T_j, given the other sufficient statistics $T_l = t_l$, $l \neq j$ and $M = m$. Denote one of these values to be $t_j^{(k)}$, $k = 1, \ldots, N$, with weight w_k that accounts for all the generated $\mathbf{Y}$ vectors that give rise to $t_j^{(k)}$. The conditional probability of observing $T_j = t_j$ has the form

$$\Pr(T_j = t_j \mid T_l = t_l, l \neq j, M = m) = \frac{w\ e^{t_j\beta_j}}{\sum_k w_k e^{t_j^{(k)}\beta_j}} \tag{1}$$

where the sum is over the subset of $\mathbf{T}$ vectors such that $(T_1^{(k)} = t_1, \ldots, T_j^{(k)} = t_j^{(k)}, \ldots, T_p^{(k)} = t_p)$ and w is the weight associated with the observed $\mathbf{t}$. The CMLE for β_j maximizes the log of this function.

Specifying nuisance variables in `condvars()` prevents `expoisson` from estimating their associated regression coefficients. These variables are still conditional variables when tallying the conditional distribution for the variables in *indepvars*.

Inferences from MLEs rely on asymptotics, and if your sample size is small, these inferences may not be valid. On the other hand, inferences from the CMLEs are exact in that they use the conditional distribution of the sufficient statistics outlined above.

For small datasets, the dependent variable can be completely determined by the data. Here the MLEs and the CMLEs are unbounded. When this occurs, `expoisson` will compute the MUE, the regression estimate that places the observed sufficient statistic at the median of the conditional distribution.

See [R] **exlogistic** for a more thorough discussion of exact estimation and related statistics.

▷ Example 1

Armitage, Berry, and Matthews (2002, 499–501) fit a log-linear model to data containing the number of cerebrovascular accidents experienced by 41 men during a fixed period, each of whom had recovered from a previous cerebrovascular accident and was hypertensive. Sixteen men received treatment, and in the original data, there are three age groups (40–49, 50–59, ≥60), but we pool the first two age groups to simplify the example. Armitage, Berry, and Matthews point out that this was not a controlled trial, but the data are useful to inquire whether there is evidence of fewer accidents for the treatment group and if age may be an important factor. The dependent variable `count` contains the number of accidents, variable `treat` is an indicator for the treatment group (1 = treatment, 0 = control), and variable `age` is an indicator for the age group (0 = 40−59; 1 = ≥60).

First, we load the data, list it, and tabulate the cerebrovascular accident counts by treatment and age group.

```
. use http://www.stata-press.com/data/r12/cerebacc
(cerebrovascular accidents in hypotensive-treated and control groups)
. list
```

	treat	count	age
1.	control	0	40/59
2.	control	0	>=60
3.	control	1	40/59
4.	control	1	>=60
5.	control	2	40/59
6.	control	2	>=60
7.	control	3	40/59

(*output omitted*)

35.	treatment	0	40/59
36.	treatment	0	40/59
37.	treatment	0	40/59
38.	treatment	0	40/59
39.	treatment	1	40/59
40.	treatment	1	40/59
41.	treatment	1	40/59

```
. tabulate treat age [fw=count]
```

hypotensive drug treatment	age group 40/59	>=60	Total
control	15	10	25
treatment	4	0	4
Total	19	10	29

Next we estimate the CMLE with `expoisson` and, for comparison, the MLE with `poisson`.

```

```

count	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
treat	-1.594306	.5573614	-2.86	0.004	-2.686714	-.5018975
age	-.5112067	.4043525	-1.26	0.206	-1.303723	.2813096
_cons	.233344	.2556594	0.91	0.361	-.2677391	.7344271

`expoisson` generates an enumeration log for each independent variable in *indepvars*. The conditional distribution of the parameter sufficient statistic is tallied for each independent variable. The conditional distribution for `treat`, for example, has 30 records containing the weights, w_k, and feasible sufficient statistics, $t^{(k)}_{\text{treat}}$. In essence, the set of points $(w_k, t^{(k)}_{\text{treat}})$, $k = 1, \ldots, 30$, tallied by `expoisson` now become the data to estimate the regression coefficient for `treat`, using (1) as the likelihood. Remember that one of the 30 $(w_k, t^{(k)}_{\text{treat}})$ must contain the observed sufficient statistic, $t_{\text{treat}} = \sum_{i=1}^{41} \texttt{treat}_i \times \texttt{count}_i = 4$, and its relative position in the sorted set of points (sorted by $t^{(k)}_{\text{treat}}$) is how the sufficient-statistic significance is computed. This algorithm is repeated for the `age` variable.

The regression coefficients for `treat` and `age` are numerically identical for both Poisson models. Both models indicate that the treatment is significant at reducing the rate of cerebrovascular accidents, $\approx e^{-1.59} \approx 0.204$, or a reduction of about 80%. There is no significant age effect.

The p-value for the treatment regression-coefficient sufficient statistic indicates that the treatment effect is a bit more significant than for the corresponding asymptotic Z statistic from `poisson`. However, the exact confidence intervals are wider than their asymptotic counterparts.

◁

Example 2

Agresti (2002) used the data from Laird and Olivier (1981) to demonstrate the Poisson model for modeling rates. The data consist of patient survival after heart valve replacement operations. The sample consists of 109 patients that are classified by type of heart valve (aortic, mitral) and by age (<55, ≥ 55). Follow-up observations cover lengths from 3 to 97 months, and the time at risk, or exposure, is stored in the variable `TAR`. The response is whether the subject died. First, we take a look at the data and then estimate the incidence rates (IRs) with `expoisson` and `poisson`.

```
. use http://www.stata-press.com/data/r12/heartvalve
(heart valve replacement data)
. list
```

	age	valve	deaths	TAR
1.	< 55	aortic	4	1259
2.	< 55	mitral	1	2082
3.	>= 55	aortic	7	1417
4.	>= 55	mitral	9	1647

The `age` variable is coded 0 for age <55 and 1 for age ≥ 55, and the `valve` variable is coded 0 for the aortic valve and 1 for the mitral valve. The total number of deaths, $M = 21$, is small enough that enumerating the conditional distributions for age and valve type is feasible and asymptotic inferences associated with standard ML Poisson regression may be questionable.

```
. expoisson deaths age valve, exposure(TAR) irr
Estimating: age
Enumerating sample-space combinations:
observation 1:   enumerations =         11
observation 2:   enumerations =         11

    ln(TAR)  |          1  (exposure)
------------------------------------------------------------------------------
```

The CMLE and the MLE are numerically identical. The death rate for the older age group is about 3.4 times higher than the younger age group, and this difference is significant at the 5% level. This means that for every death in the younger group each month, we would expect about three deaths in the older group. The IR estimate for valve type is approximately 0.72, but it is not significantly different from one. The exact Poisson confidence intervals are a bit wider than the asymptotic CIs.

You can use `ir` (see [ST] **epitab**) to estimate IRs and exact CIs for one covariate, and we compare these CIs with those from `expoisson`, where we estimate the incidence rate by using age only.

```

mid-p-value computed for the probabilities and CIs
```

Both `ir` and `expoisson` give identical IRs and p-values. Both report the two-sided exact significance by using the mid-p-value rule that accounts for the discreteness in the distribution by subtracting $p_{1/2} = \Pr(T = t)/2$ from $p_l = \Pr(T \leq t)$ and $p_g = \Pr(T \geq t)$, computing $2 \times \min(p_l - p_{1/2}, p_g - p_{1/2})$. By default, `expoisson` will not use the mid-p-value rule (when you exclude the `midp` option), and here the two-sided exact significance would be $2 \times \min(p_l, p_g) = 0.0158$. The confidence intervals differ because `expoisson` uses the mid-p-value rule when computing the confidence intervals, yet

ir does not. You can verify this by executing expoisson without the midp option for this example; you will get the same CIs as ir.

You can replay expoisson to view the conditional scores test or the conditional probabilities test by using the test() option.

All the statistics for expoisson are defined in *Methods and formulas* of [R] **exlogistic**. Apart from enumerating the conditional distributions for the logistic and Poisson sufficient statistics, computationally, the primary difference between exlogistic and expoisson is the weighting values in the likelihood for the parameter sufficient statistics. ◁

▷ Example 3

In this example, we fabricate data that will demonstrate the difference between the CMLE and the MUE when the CMLE is not infinite. A difference in these estimates will be more pronounced when the probability of the coefficient sufficient statistic is skewed when plotted as a function of the regression coefficient.

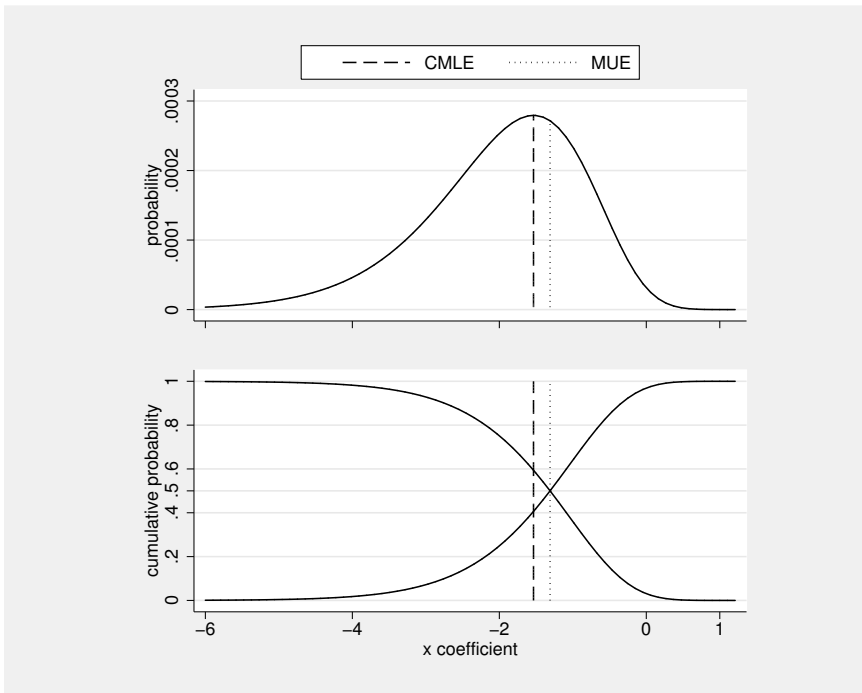
(*) median unbiased estimates (MUE)
```

We observe (x_i, y_i), $i = 1, \ldots, 9$. If we condition on $m = \sum_{i=1}^{9} y_i = 12$, the conditional distribution of $T_x = \sum_i Y_i x_i$ has a size of 5,479 elements. For each entry in this enumeration, a realization of $Y_i = y_i^{(k)}$, $k = 1, \ldots, 5{,}479$, is generated such that $\sum_i y_i^{(k)} = 12$. One of these realizations produces the observed $t_x = \sum_i y_i x_i \approx 1.5234$.

Below is a graphical display comparing the CMLE with the MUE. We plot $\Pr(T_x = t_x \mid M = 12, \beta_x)$ versus β_x, $-6 \leq \beta_x \leq 1$, in the upper panel and the cumulative probabilities, $\Pr(T_x \leq t_x \mid M = 12, \beta_x)$ and $\Pr(T_x \geq t_x \mid M = 12, \beta_x)$, in the lower panel.



The location of the CMLE, indicated by the dashed line, is at the mode of the probability profile, and the MUE, indicated by the dotted line, is to the right of the mode. If we solve for the $\beta_x^{(u)}$ and $\beta_x^{(l)}$ such that $\Pr(T_x \leq t_x \mid M = 12, \beta_x^{(u)}) = 1/2$ and $\Pr(T_x \geq t_x \mid M = 12, \beta_x^{(l)}) = 1/2$, the MUE is $(\beta_x^{(u)} + \beta_x^{(l)})/2$. As you can see in the lower panel, the MUE cuts through the intersection of these cumulative probability profiles.

◁

❑ Technical note

The memory(#) option limits the amount of memory that expoisson will consume when computing the conditional distribution of the parameter sufficient statistics. memory() is independent of the data maximum memory setting (see set max_memory in [D] **memory**), and it is possible for expoisson to exceed the memory limit specified in set max_memory without terminating. By default, a log is provided that displays the number of enumerations (the size of the conditional distribution) after processing each observation. Typically, you will see the number of enumerations increase, and then at some point they will decrease as the multivariate shift algorithm (Hirji, Mehta, and Patel 1987) determines that some of the enumerations cannot achieve the observed sufficient statistics of the conditioning variables. When the algorithm is complete, however, it is necessary to store the conditional distribution of the parameter sufficient statistics as a dataset. It is possible, therefore, to get a memory error when the algorithm has completed if there is not enough memory to store the conditional distribution.

❑

❑ Technical note

Computing the conditional distributions and reported statistics requires data sorting and numerical comparisons. If there is at least one single-precision variable specified in the model, expoisson will make comparisons with a relative precision of 2^{-5}. Otherwise, a relative precision of 2^{-11} is used. Be careful if you use recast to promote a single-precision variable to double precision (see [D] **recast**). You might try listing the data in full precision (maybe %20.15g; see [D] **format**) to make sure that this is really what you want. See [D] **data types** for information on precision of numeric storage types.

❑

Saved results

expoisson saves the following in e():

Scalars

e(N)	number of observations
e(k_groups)	number of groups
e(relative_weight)	relative weight for the observed e(sufficient) and e(condvars)
e(sum_y)	sum of *depvar*
e(k_indvars)	number of independent variables
e(k_condvars)	number of conditioning variables
e(midp)	mid-*p*-value rule indicator
e(eps)	relative difference tolerance

Macros

`e(probtest)`	conditional probability tests for *indepvars*
`e(p_probtest)`	p-value for `e(probtest)`

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`expoisson` is implemented as an ado-file.

Let $\{Y_1, Y_2, \ldots, Y_n\}$ be a set of n independent Poisson random variables. For each $i = 1, \ldots, n$, we observe $Y_i = y_i \geq 0$, and associated with each observation is the covariate row vector of length p, $\mathbf{x}_i = (x_{i1}, \ldots, x_{ip})$. Denote $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_p)^T$ to be the column vector of regression parameters and θ to be the constant. The sufficient statistic for β_j is $T_j = \sum_{i=1}^n Y_i x_{ij}$, $j = 1, \ldots, p$, and for θ is $M = \sum_{i=1}^n Y_i$. We observe $T_j = t_j$, $t_j = \sum_{i=1}^n y_i x_{ij}$, and $M = m$, $m = \sum_{i=1}^n y_i$. Let κ_i be the exposure for the ith observation. Then the probability of observing $(Y_1 = y_1, Y_2 = y_2, \ldots, Y_n = y_n)$ is

$$\Pr(Y_1 = y_1, \ldots, Y_n = y_n \mid \boldsymbol{\beta}, \mathbf{X}, \boldsymbol{\kappa}) = \frac{\exp(m\theta + \mathbf{t}\boldsymbol{\beta})}{\exp\{\sum_{i=1}^n \kappa_i \exp(\theta + \mathbf{x}_i\boldsymbol{\beta})\}} \prod_{i=1}^n \frac{\kappa_i^{y_i}}{y_i!}$$

where $\mathbf{t} = (t_1, \ldots, t_p)$, $\mathbf{X} = (\mathbf{x}_1^T, \ldots, \mathbf{x}_n^T)^T$, and $\boldsymbol{\kappa} = (\kappa_1, \ldots, \kappa_n)^T$.

The joint distribution of the sufficient statistics $(\mathbf{T}, M)$ is obtained by summing over all possible sequences $Y_1 \geq 0, \ldots, Y_n \geq 0$ such that $\mathbf{T} = \mathbf{t}$ and $M = m$. This probability function is

$$\Pr(T_1 = t_1, \ldots, T_p = t_p, M = m \mid \boldsymbol{\beta}, \mathbf{X}, \boldsymbol{\kappa}) = \frac{\exp(m\theta + \mathbf{t}\boldsymbol{\beta})}{\exp\{\sum_{i=1}^n \kappa_i \exp(\theta + \mathbf{x}_i\boldsymbol{\beta})\}} \left(\sum_{\mathbf{u}} \prod_{i=1}^n \frac{\kappa_i^{u_i}}{u_i!} \right)$$

where the sum $\sum_{\mathbf{u}}$ is over all nonnegative vectors $\mathbf{u}$ of length n such that $\sum_{i=1}^n u_i = m$ and $\sum_{i=1}^n u_i \mathbf{x}_i = \mathbf{t}$.

Conditional distribution

Without loss of generality, we will restrict our discussion to the conditional distribution of the sufficient statistic for β_1, T_1. If we condition on observing $M = m$ and $T_2 = t_2, \ldots, T_p = t_p$, the probability function of $(T_1 \mid \beta_1, T_2 = t_2, \ldots, T_p = t_p, M = m)$ is

$$\Pr(T_1 = t_1 \mid \beta_1, T_2 = t_2, \ldots, T_p = t_p, M = m) = \frac{\left(\sum_{\mathbf{u}} \prod_{i=1}^n \frac{\kappa_i^{u_i}}{u_i!} \right) e^{t_1\beta_1}}{\sum_{\mathbf{v}} \left(\prod_{i=1}^n \frac{\kappa_i^{v_i}}{v_i!} \right) e^{\beta_1 \sum_i v_i x_{i1}}} \tag{2}$$

where the sum $\sum_{\mathbf{u}}$ is over all nonnegative vectors $\mathbf{u}$ of length n such that $\sum_{i=1}^{n} u_i = m$ and $\sum_{i=1}^{n} u_i \mathbf{x}_i = \mathbf{t}$, and the sum $\sum_{\mathbf{v}}$ is over all nonnegative vectors $\mathbf{v}$ of length n such that $\sum_{i=1}^{n} v_i = m$, $\sum_{i=1}^{n} v_i x_{i2} = t_2, \ldots, \sum_{i=1}^{n} v_i x_{ip} = t_p$. The CMLE for β_1 is the value that maximizes the log of (1). This optimization task is carried out by `ml` (see [R] **ml**), using the conditional distribution of $(T_1 \mid T_2 = t_2, \ldots, T_p = t_p, M = m)$ as a dataset. This dataset consists of the feasible values and weights for T_1,

$$\left\{ \left(s_1, \prod_{i=1}^{n} \frac{\kappa_i^{v_i}}{v_i!} \right) : \sum_{i=1}^{n} v_i = m, \sum_{i=1}^{n} v_i x_{i1} = s_1, \sum_{i=1}^{n} v_i x_{i2} = t_2, \ldots, \sum_{i=1}^{n} v_i x_{ip} = t_p \right\}$$

Computing the CMLE, MUE, confidence intervals, conditional hypothesis tests, and sufficient statistic p-values is discussed in *Methods and formulas* of [R] **exlogistic**. The only difference between the two techniques is the use of the weights; that is, the weights for exact logistic are the combinatorial coefficients, $c(\mathbf{t}, m)$, in (1) of *Methods and formulas* in [R] **exlogistic**. `expoisson` and `exlogistic` use the same `ml` likelihood evaluator to compute the CMLEs as well as the same ado-programs and Mata functions to compute the MUEs and estimate statistics.

Title

expoisson postestimation — Postestimation tools for expoisson

Description

The following postestimation command is of special interest after `expoisson`:

Command	Description
`estat se`	report coefficients or IRRs and their asymptotic standard errors

For information about this command, see below.

The following standard postestimation command is also available:

Command	Description
`estat summarize`	estimation sample summary

See [R] **estat** for details.

Special-interest postestimation command

`estat se` reports regression coefficients or incidence-rate asymptotic standard errors. The estimates are stored in the matrix `r(estimates)`.

Syntax for estat se

```
estat se [, irr]
```

Menu

Statistics > Postestimation > Reports and statistics

Option for estat se

`irr` requests that the incidence-rate ratios and their asymptotic standard errors be reported. The default is to report the coefficients and their asymptotic standard errors.

Remarks

▷ Example 1

To demonstrate `estat se` after `expoisson`, we use the British physicians smoking data.

```
. use http://www.stata-press.com/data/r12/smokes

Title

fracpoly — Fractional polynomial regression

Syntax

Fractional polynomial regression

```
fracpoly [ , fracpoly_options ] : regression_cmd [ yvar1 [ yvar2 ] ]
    xvar1 [ # [ #... ] ] [ xvar2 [ # [ #... ] ] ] [...] [ xvarlist ] [ if ] [ in ] [ weight ]
    [ , regression_cmd_options ]
```

Display table showing the best fractional polynomial model for each degree

```
fracpoly, compare
```

Create variables containing fractional polynomial powers

```
fracgen varname # [ # ... ] [ if ] [ in ] [ , fracgen_options ]
```

fracpoly_options	Description
Model	
`degree(#)`	degree of fractional polynomial to fit; default is `degree(2)`
Model 2	
`noscaling`	suppress scaling of first independent variable
`noconstant`	suppress constant term
`powers(`*numlist*`)`	list of fractional polynomial powers from which models are chosen
`center(`*cent_list*`)`	specification of centering for the independent variables
`all`	include out-of-sample observations in generated variables
Reporting	
`log`	display iteration log
`compare`	compare models by degree
display_options	control column formats and line width

regression_cmd_options	Description
Model 2	
regression_cmd_options	options appropriate to the regression command in use

All weight types supported by *regression_cmd* are allowed; see [U] **11.1.6 weight**.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

where

cent_list is a comma-separated list with elements *varlist*:{mean|#|no}, except that the first element may optionally be of the form {mean|#|no} to specify the default for all variables.

regression_cmd may be clogit, glm, intreg, logistic, logit, mlogit, nbreg, ologit, oprobit, poisson, probit, qreg, regress, rreg, stcox, stcrreg, streg, or xtgee.

fracgen_options	Description
Main	
center(no|mean|#)	center *varname* as specified; default is center(no)
noscaling	suppress scaling of *varname*
restrict([*varname*] [*if*])	compute centering and scaling using specified subsample
replace	replace variables if they exist

Menu

fracpoly

Statistics > Linear models and related > Fractional polynomials > Fractional polynomial regression

fracgen

Statistics > Linear models and related > Fractional polynomials > Create fractional polynomial powers

Description

fracpoly fits fractional polynomials (FPs) in $xvar_1$ as part of the specified regression model. After execution, fracpoly leaves variables in the dataset named I*xvar*__1, I*xvar*__2, ..., where *xvar* represents the first four letters of the name of $xvar_1$. The new variables contain the best-fitting FP powers of $xvar_1$.

Covariates other than $xvar_1$, which are optional, are specified in $xvar_2$, ..., and *xvarlist*. They may be modeled linearly and with specified FP transformations. Fractional polynomial powers are specified by typing numbers after the variable's name. A variable name typed without numbers is entered linearly.

fracgen creates new variables named *varname*_1, *varname*_2, ..., containing FP powers of *varname* by using the powers (# [#...]) specified.

See [R] **fracpoly postestimation** for information on fracplot and fracpred.

See [R] **mfp** for multivariable FP model fitting.

Options for fracpoly

Model

degree(#) determines the degree of FP to be fit. The default is degree(2), that is, a model with two power terms.

Model 2

noscaling suppresses scaling of $xvar_1$ and its powers.

`noconstant` suppresses the regression constant if this is permitted by *regression_cmd*.

`powers(`*numlist*`)` is the set of FP powers from which models are to be chosen. The default is `powers(-2,-1,-.5,0,.5,1,2,3)` (0 means log).

`center(`*cent_list*`)` defines the centering for the covariates $xvar_1$, $xvar_2$, ..., *xvarlist*. The default is `center(mean)`. A typical item in *cent_list* is *varlist*`:{mean|#|no}`. Items are separated by commas. The first item is special because *varlist*`:` is optional, and if omitted, the default is (re)set to the specified value (`mean` or `#` or `no`). For example, `center(no, age:mean)` sets the default to `no` and sets the centering for `age` to `mean`.

regression_cmd_options are options appropriate to the regression command in use. For example, for `stcox`, *regression_cmd_options* may include `efron` or some alternate method for handling tied failures.

`all` includes out-of-sample observations when generating the best-fitting FP powers of $xvar_1$, $xvar_2$, etc. By default, the generated FP variables contain missing values outside the estimation sample.

Reporting

`log` displays deviances and (for `regress`) residual standard deviations for each FP model fit.

`compare` reports a closed-test comparison between FP models.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Options for fracgen

Main

`center(no|mean|#)` specifies whether *varname* is to be centered; the default is `center(no)`.

`noscaling` suppresses scaling of *varname*.

`restrict(`[*varname*] [*if*]`)` specifies that centering and scaling be computed using the subsample identified by *varname* and `if`.

The subsample is defined by the observations for which *varname* $\neq 0$ that also meet the `if` conditions. Typically, *varname* $= 1$ defines the subsample and *varname* $= 0$ indicates observations not belonging to the subsample. For observations whose subsample status is uncertain, *varname* should be set to a missing value; such observations are dropped from the subsample.

By default, `fracgen` computes the centering and scaling by using the sample of observations identified in the [*if*] [*in*] options. The `restrict()` option identifies a subset of this sample.

`replace` specifies that any existing variables named *varname*`_1`, *varname*`_2`, ... may be replaced.

Remarks

Remarks are presented under the following headings:

Introduction
fracpoly

Models with several continuous covariates
Examples

Introduction

Regression models based on FP functions of a continuous covariate are described by Royston and Altman (1994b). Detailed examples using an earlier and rather more complex version of this set of commands are presented by Royston and Altman (1994a).

FPs increase the flexibility afforded by the family of conventional polynomial models. Although polynomials are popular in data analysis, linear and quadratic functions are severely limited in their range of curve shapes, whereas cubic and higher-order curves often produce undesirable artifacts, such as edge effects and waves.

A polynomial of degree m may be written as

$$\beta_0 + \beta_1 x + \beta_2 x^2 + \cdots + \beta_m x^m$$

whereas FP of degree m has m integer and/or fractional powers $p_1 < \cdots < p_m$,

$$\beta_0 + \beta_1 x^{(p_1)} + \beta_2 x^{(p_2)} + \cdots + \beta_m x^{(p_m)}$$

where for a power, p,

$$x^{(p)} = \begin{cases} x^p & \text{if } p \neq 0 \\ \log x & \text{if } p = 0 \end{cases}$$

x must be positive. An FP of first degree ($m = 1$) involves one power or log transformation of x.

This family of FP functions may be extended in a mathematically natural way to include repeated powers. An FP of degree m with exactly m repeated powers of p is defined as

$$\beta_0 + \beta_1 x^{(p)} + \beta_2 x^{(p)} \log x + \cdots + \beta_m x^{(p)} (\log x)^{m-1}$$

For example, an FP of second degree ($m = 2$) with repeated powers of 0.5 is

$$\beta_0 + \beta_1 x^{0.5} + \beta_2 x^{0.5} \log x$$

A general FP may include some unique and some repeated powers. For example, one with powers $(-1, 1, 3, 3)$ is

$$\beta_0 + \beta_1 x^{-1} + \beta_2 x + \beta_3 x^3 + \beta_4 x^3 \log x$$

The permitted powers are restricted to the set $\{-2, -1, -0.5, 0, 0.5, 1, 2, 3\}$ because our experience using FPs in data analysis indicates that including extra powers in the set is not often worthwhile.

Now we consider using FPs in regression modeling. If the values of the powers $p_1, \ldots, p_m$ were known, the FP would resemble a conventional multiple linear regression model with coefficients $\beta_0, \beta_1, \ldots, \beta_m$. However, the powers are not (usually) known and must be estimated, together with the coefficients, from the data. Estimation involves a systematic search for the best power or combination of powers from the permitted set. For each possible combination, a linear regression model as just described is fit, and the corresponding deviance (defined as minus twice the log likelihood) is noted. The model with the lowest deviance is deemed to have the best fit, and the corresponding powers and regression coefficients constitute the final FP model. In practice, $m = 2$ is often sufficient (Royston and Sauerbrei 2008, 76).

fracpoly

`fracpoly` finds and reports a multiple regression model comprising the best-fitting powers of $xvar_1$ together with other covariates specified by $xvar_2$, ..., *xvarlist*. The model that is fit depends on the type of *regression_cmd* used.

The regression output for the best-fitting model may be reproduced by typing *regression_cmd* without variables or options. `predict`, `test`, etc., may be used after `fracpoly`; the results will depend on *regression_cmd*.

The standard errors of the fitted values (as estimated after use of `fracpoly` by using `predict` or `fracpred` with the `stdp` option) are somewhat too low because no allowance has been made for the estimation of the powers.

If $xvar_1$ has any negative or zero values, `fracpoly` subtracts the minimum of *xvar* from *xvar* and then adds the rounding (or counting) interval. The interval is defined as the smallest positive difference between the ordered values of *xvar*. After this change of origin, the minimum value of $xvar_1$ is positive, so FPs (which require $xvar_1 > 0$) can be used. Unless the `noscaling` option is used, `fracpoly` scales the resulting variable by a power of 10 calculated from the data. The scaling is designed to improve numerical stability when fitting FP models.

After execution, `fracpoly` leaves in the dataset variables named `Ixvar__1`, `Ixvar__2`, ..., which are the best-fitting FP powers of $xvar_1$ (calculated, if necessary, after a change in origin and scale as just described, and if centering is specified, with a constant added to or subtracted from the values after FP transformation). Other variables, whose names follow the same convention, are left in the dataset if $xvar_2$ has been specified.

Centering

As discussed by Garrett (1995, 1998), covariate centering is a sensible, indeed often essential, step when reporting and interpreting the results of multiple regression models. For this and other reasons, centering has been introduced as the default option in `fracpoly`. As written, the familiar straight-line regression function $E[y|x] = \beta_0 + \beta_1 x$ is "centered" to 0 in that $\beta_0 = E[y|0]$. This is fine if $x = 0$ is a sensible base point. However, the sample values of x may not even encompass 0 (this is usually the case when FP models are contemplated). Then β_0 is a meaningless intercept, and the standard error of its estimate $\widehat{\beta}_0$ will be large. For FP model $E[y|x] = \beta_0 + \beta_1 x^{(p)}$, the point $x^{(p)} = 0$ may even correspond to $x = \infty$ (consider $p < 0$). The scheme adopted by `fracpoly` is to center on the mean of x. For example, for the FP $E[y|x] = \beta_0 + \beta_1 x^p + \beta_1 x^q$, `fracpoly` actually fits the model

$$E[y|x] = \beta_0 + \beta_1 \left(x^p - \overline{x}^p\right) + \beta_2 \left(x^q - \overline{x}^q\right)$$

where $\overline{x}$ is the sample mean of the x values and $E[y|\overline{x}] = \beta_0$, giving β_0 a respectable interpretation as the predicted value of y at the mean of x. This approach has the advantage that plots of the fitted values and 95% confidence intervals for $E[y|x]$ as a function of x, even within a multiple regression model, are always sensible (provided that the other predictors are suitably centered—otherwise, the confidence limits can be alarmingly wide).

Sometimes centering on the mean is not appropriate, an example being a binary covariate where often you will want to center on the lower value, usually 0 (that is, not center). You should then use the `center()` option to override the default. An example is `center(x1:mean,x2-x5:no,x6:1)`.

Output with the compare option

If the `compare` option is used, `fracpoly` displays a table showing the best FP model for each degree $k < m$ (including the model without x and the model linear in x). Deviance differences between each FP model and the degree m model are also reported along with the corresponding p-values (Royston and Altman 1994b; Royston and Sauerbrei 2008).

The `compare` option implements a closed-test approach to selecting an FP model. It has the advantage of preserving the type I error probability at a nominal value. For example, suppose a nominal 5% significance level was chosen, and the test of FP2 versus the null model (that is, omitting x) was not significant. No further tests among FP models would then be done, and x would be considered nonsignificant, regardless of the results of any further model comparisons.

fracgen

The basic syntax of `fracgen` is

`fracgen` *varname* # [# ...]

Each power (represented by # in the syntax diagram) should be separated by a space. `fracgen` creates new variables called *varname*_1, *varname*_2, etc. Each variable is labeled according to its power, preliminary linear transformation, and centering, if applied.

Positive or negative powers of *varname* are defined in the usual way. A power of zero is interpreted as log.

Models with several continuous covariates

`fracpoly` estimates powers for FP models in just one continuous covariate ($xvar_1$), though other covariates of any kind ($xvar_2$, ..., *xvarlist*) may be included as linear or predefined FP terms. An algorithm was suggested by Royston and Altman (1994b) for the joint estimation of FP models in several continuous covariates. It was later refined by Sauerbrei and Royston (1999) and is implemented in the Stata command `mfp`. See [R] **mfp** as well as Royston and Ambler (1998) and Royston and Sauerbrei (2008).

Examples

▷ Example 1

Consider the serum immunoglobulin G (IgG) dataset from Isaacs et al. (1983), which consists of 298 independent observations in young children. The dependent variable `sqrtigg` is the square root of the IgG concentration, and the independent variable `age` is the age of each child. (Preliminary Box–Cox analysis shows that a square root transformation removes the skewness in IgG.) The aim is to find a model that accurately predicts the mean of `sqrtigg` given `age`. We use `fracpoly` to find the best FP model of degree 2 (the default option) and graph the resulting fit and 95% confidence interval:

```
. use http://www.stata-press.com/data/r12/igg
(Immunoglobulin in children)
. fracpoly: regress sqrtigg age
........
-> gen double Iage__1 = age^-2-.1299486216 if e(sample)
-> gen double Iage__2 = age^2-7.695349038 if e(sample)
```

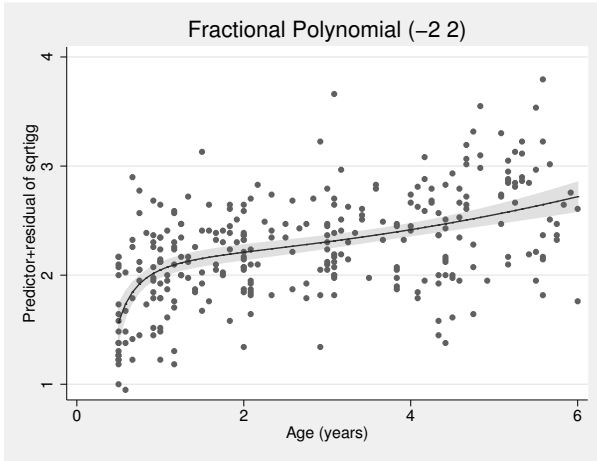
```
Deviance:  319.45. Best powers of age among 44 models fit: -2 2.
. fracplot age, msize(small)
```



The new variables created by `fracpoly` contain the best-fitting FP powers of `age`, as centered by `fracpoly`. For example, `Iage__1` is centered by subtracting the mean of `age` raised to the power -2. In general, the variables created by `fracpoly` are centered and possibly scaled, which is reflected in the estimated regression coefficients and intercept. Centering does have its advantages (see the *Centering* section earlier in this entry); however, sometimes you may want estimation for uncentered variables. To obtain regression results for uncentered and unscaled FP variables, specify options `center(no)` and `noscaling` to `fracpoly`. For a more detailed discussion, see Royston and Sauerbrei (2008, sec. 4.11).

The fitted curve has an asymmetric S shape. This model has powers $(-2, 2)$ and deviance 319.45. As many as 44 models have been quietly fit in the search for the best powers. Now let's look at models of degree ≤ 4:

```
. fracpoly, degree(4) compare: regress sqrtigg age

```
(*) P-value from deviance difference comparing reported model with m = 4 model
```

It appears that the degree 4 FP model is not significantly different from the other FP models (at the 5% level).

Let's compare the curve shape from the $m = 2$ model with that from a conventional quartic polynomial, whose fit turns out to be significantly better than a cubic (not shown). We use the ability of `fracpoly` both to generate the required powers of `age`, namely, $(1, 2, 3, 4)$ for the quartic and $(-2, 2)$ for the second-degree FP, and to fit the model. We fit both models and graph the resulting curves:

```
. fracpoly: regress sqrtigg age 1 2 3 4
-> gen double Iage__1 = age-2.774049213 if e(sample)
-> gen double Iage__2 = age^2-7.695349038 if e(sample)
-> gen double Iage__3 = age^3-21.34727694 if e(sample)
-> gen double Iage__4 = age^4-59.21839681 if e(sample)
```

```

The quartic curve has an unsatisfactory wavy appearance that is implausible for the known behavior of IgG, the serum level of which increases throughout early life. The FP curve increases monotonically and is therefore biologically the more plausible curve. The two models have approximately the same deviance.

◁

▷ Example 2

Data from Smith et al. (1992) contain times to complete healing of leg ulcers in a randomized controlled clinical trial of two treatments in 192 elderly patients. Several covariates were available, of which an important one is `mthson`, the number of months since the recorded onset of the ulcer. Because the response variable is time to an event of interest and some (in fact, about one-half) of the times are censored, using Cox regression to analyze the data is appropriate. We consider FPs in `mthson`, adjusting for four other covariates: `age`; `ulcarea`, the area of tissue initially affected by the ulcer; `deepppg`, a binary variable indicating the presence or absence of deep vein involvement; and `treat`, a binary variable indicating treatment type. We fit FPs of degree 1 and 2:

```
. use http://www.stata-press.com/data/r12/legulcer, clear
(Leg ulcer clinical trial)
. stset ttevent, fail(cens)
```

(*output omitted*)

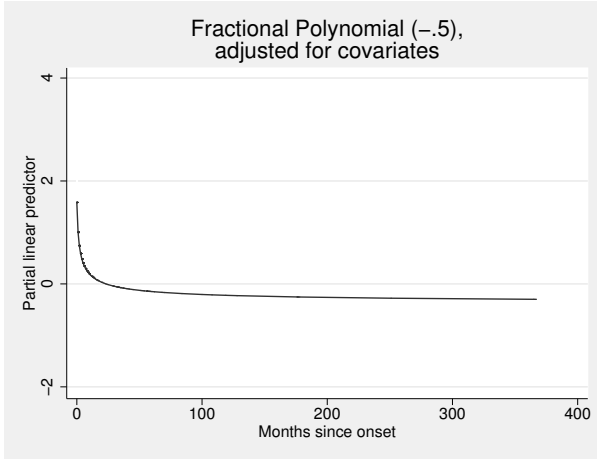
The best-fit FP of degree 2 has powers $(0.5, 0.5)$ and deviance 736.71. However, this model does not fit significantly better than the FP of degree 1 (at the 5% level), which has power -0.5 and deviance 738.97. We prefer the model with $m = 1$, for which the partial linear predictor is shown on the next page.

```
. quietly fracpoly, degree(1): stcox mthson age ulcarea deepppg treat, nohr
. fracplot, ytitle(Partial linear predictor) m(i) ciopts(bcolor(white))
```



The hazard for healing is much higher for patients whose ulcer is of recent onset than for those who have had an ulcer for many months.

`fracpoly` has automatically centered the predictors on their mean values, but because in Cox regression there is no constant term, we cannot see the effects of centering in the table of regression estimates. The effects would be present if we were to graph the baseline hazard or survival function because these functions are defined with all predictors set equal to 0.

A more appropriate analysis of this dataset, if one wished to model all the predictors, possibly with FP functions, would be to use `mfp`; see [R] **mfp**.

◁

Saved results

In addition to what *regression_cmd* saves, `fracpoly` saves the following in `e()`:

Scalars

`e(fp_N)`	number of nonmissing observations
`e(fp_dev)`	deviance for FP model of degree m
`e(fp_df)`	FP model degrees of freedom
`e(fp_d0)`	deviance for model without *xvar*$_1$
`e(fp_s0)`	residual SD for model without *xvar*$_1$
`e(fp_dlin)`	deviance for model linear in *xvar*$_1$
`e(fp_slin)`	residual SD for model linear in *xvar*$_1$
`e(fp_d1)`, `e(fp_d2)`, ...	deviances for FP models of degree 1,2,...,m
`e(fp_s1)`, `e(fp_s2)`, ...	residual SDs for FP models of degree 1,2,...,m

Macros

`e(fp_cmd)`	`fracpoly`
`e(cmdline)`	command as typed
`e(fp_depv)`	*yvar*$_1$ (*yvar*$_2$
`e(fp_rhs)`	*xvar*$_1$
`e(fp_base)`	variables in *xvar*$_2$, ..., *xvarlist* after centering and FP transformation
`e(fp_xp)`	I*xvar*__1, I*xvar*__2, etc.
`e(fp_fvl)`	variables in model finally estimated
`e(fp_wgt)`	weight type or `""`
`e(fp_wexp)`	weight expression if `'e(fp_wgt)' != ""`
`e(fp_pwrs)`	powers for FP model of degree m
`e(fp_x1)`, `e(fp_x2)`, ...	*xvar*$_1$ and variables in model
`e(fp_k1)`, `e(fp_k2)`, ...	powers for FP models of degree 1,2,...,m

Residual SDs are stored only when *regression_cmd* is `regress`.

Methods and formulas

`fracpoly` and `fracgen` are implemented as ado-files.

The general definition of an FP, accommodating possible repeated powers, may be written for functions $H_1(x), \ldots, H_m(x)$ as

$$\beta_0 + \sum_{j=1}^{m} \beta_j H_j(x)$$

where $H_1(x) = x^{(p_1)}$ and for $j = 2, \ldots, m$,

$$H_j(x) = \begin{cases} x^{(p_j)} & \text{if } p_j \neq p_{j-1} \\ H_{j-1}(x) \log x & \text{if } p_j = p_{j-1} \end{cases}$$

For example, an FP of degree 3 with powers $(1, 3, 3)$ has $H_1(x) = x$, $H_2(x) = x^3$, and $H_3(x) = x^3 \log x$ and equals $\beta_0 + \beta_1 x + \beta_2 x^3 + \beta_3 x^3 \log x$.

An FP model of degree m is taken to have $2m + 1$ degrees of freedom (df): one for β_0 and one for each β_j and its associated power. Because the powers in an FP are chosen from a finite set rather than from the entire real line, the df defined in this way are approximate.

The deviance D of a model is defined as -2 times its maximized log likelihood. For normal-errors models, we use the formula

$$D = n\left(1 - \bar{l} + \log \frac{2\pi \text{RSS}}{n}\right)$$

where n is the sample size, $\bar{l}$ is the mean of the lognormalized weights ($\bar{l} = 0$ if the weights are all equal), and RSS is the residual sum of squares as fit by `regress`.

The `compare` option causes `fracpoly` to report a table comparing FP models of degree $k < m$ to the degree m FP model. Suppose that we are comparing FP regression models with degrees k and m. The p-values reported by `compare` are calculated differently for normal and nonnormal regressions. Let D_k and D_m be the deviances of the models with degrees k and m, respectively. For normal-errors models such as `regress`, a variance ratio F is calculated as

$$F = \frac{n_2}{n_1}\left\{\exp\left(\frac{D_k - D_m}{n}\right) - 1\right\}$$

where n_1 is the numerator df (here, $2m - 2k$) and n_2 is the denominator df (equal to rdf $- 2m$, where rdf is the residual df for the regression model involving only the covariates in *xvar*$_2$, if any, but not x). The p-value is obtained by referring F to an F distribution on (n_1, n_2) df.

For nonnormal models (`clogit`, `glm`, `logistic`, ... `stcox`, or `streg`; not `regress`), the p-value is obtained by referring $D_k - D_m$ to a χ^2 distribution on $2m - 2k$ df. These p-values for comparing models are approximate and are typically somewhat conservative (Royston and Altman 1994b).

The component-plus-residual values graphed by `fracplot` are calculated as follows: let the data consist of triplets $(y_i, x_i, \mathbf{z}_i)$, $i = 1, \ldots, n$, where $\mathbf{z}_i$ is the vector of covariates for the ith observation, after applying possible FP transformation and centering as described earlier. Let $\widehat{\eta}_i = \widehat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}'\widehat{\boldsymbol{\beta}} + \mathbf{z}_i'\widehat{\boldsymbol{\gamma}}$ be the linear predictor from the FP model, as given by the `fracpred` command, or equivalently, by the `predict` command with the `xb` option, after the use of `fracpoly`. Here $\mathbf{H}(x_i) = \{H_1(x_i), \ldots, H_m(x_i)\}'$ is the vector of FP functions described above, $\mathbf{H}(x_0) = \{H_1(x_0), \ldots, H_m(x_0)\}'$ is the vector of centering to x_0 (x_0 is often chosen to be the mean of the x_i), $\widehat{\boldsymbol{\beta}}$ is the estimated parameter vector, and $\widehat{\boldsymbol{\gamma}}$ is the estimated parameter vector for the covariates. The values $\widehat{\eta}_i^* = \widehat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}'\widehat{\boldsymbol{\beta}}$ represent the behavior of the FP model for x at fixed values $\mathbf{z} = \mathbf{0}$ of the (centered) covariates. The ith component-plus-residual is defined as $\widehat{\eta}_i^* + d_i$, where d_i is the deviance residual for the ith observation. For normal-errors models, $d_i = \sqrt{w_i}(y_i - \widehat{\eta}_i)$, where w_i is the case weight (or 1, if *weight* is not specified). For logistic, Cox, and generalized linear regression models, see [R] **logistic**, [R] **probit**, [ST] **stcox**, and [R] **glm**, respectively, for the formula for d_i. The formula for `poisson` models is the same as that for `glm` with `family(poisson)`. For `stcox`, d_i is the partial martingale residual (see [ST] **stcox postestimation**).

Acknowledgment

`fracpoly` and `fracgen` were written by Patrick Royston, MRC Clinical Trials Unit, London.

Title

fracpoly postestimation — Postestimation tools for fracpoly

Description

The following postestimation commands are of special interest after `fracpoly`:

Command	Description
`fracplot`	plot data and fit from most recently fit fractional polynomial model
`fracpred`	create variable containing prediction, deviance residuals, or SEs of fitted values

For information about these commands, see below.

The following standard postestimation commands are also available if available after *regression_cmd*:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation commands

`fracplot` plots the data and fit, with 95% confidence limits, from the most recently fit fractional polynomial (FP) model. The data and fit are plotted against *varname*, which may be $xvar_1$ or another of the covariates ($xvar_2$, ..., or a variable from *xvarlist*). If *varname* is not specified, $xvar_1$ is assumed.

`fracpred` creates *newvar* containing the fitted index or deviance residuals for the whole model, or the fitted index or its standard error for *varname*, which may be $xvar_1$ or another covariate.

Syntax for predict

The behavior of `predict` following `fracpoly` is determined by *regression_cmd*. See the corresponding *regression_cmd* **postestimation** entry for available `predict` options.

Also see information on `fracpred` below.

Syntax for fracplot and fracpred

Plot data and fit from most recently fit fractional polynomial model

`fracplot` [*varname*] [*if*] [*in*] [, *fracplot_options*]

Create variable containing the prediction, deviance residuals, or SEs of fitted values

`fracpred` *newvar* [, *fracpred_options*]

fracplot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Fitted line	
`lineopts(`*cline_options*`)`	affect rendition of the fitted line
CI plot	
`ciopts(`*area_options*`)`	affect rendition of the confidence bands
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

fracpred_options	Description
`for(`*varname*`)`	compute prediction for *varname*
`dresid`	compute deviance residuals
`stdp`	compute standard errors of the fitted values *varname*

`fracplot` is not allowed after `fracpoly` or `mfp` with `clogit`, `mlogit`, or `stcrreg`. `fracpred, dresid` is not allowed after `fracpoly` or `mfp` with `clogit`, `mlogit`, or `stcrreg`.

Menu

fracplot

Statistics > Linear models and related > Fractional polynomials > Fractional polynomial regression plot

fracpred

Statistics > Linear models and related > Fractional polynomials > Fractional polynomial prediction

Options for fracplot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Fitted line

`lineopts(`*cline_options*`)` affect the rendition of the fitted line; see [G-3] ***cline_options***.

CI plot

`ciopts(`*area_options*`)` affect the rendition of the confidence bands; see [G-3] ***area_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Options for fracpred

`for(`*varname*`)` specifies (partial) prediction for variable *varname*. The fitted values are adjusted to the value specified by the `center()` option in `fracpoly`.

`dresid` specifies that deviance residuals be calculated.

`stdp` specifies calculation of the standard errors of the fitted values *varname*, adjusted for all the other predictors at the values specified by `center()`.

Remarks

`fracplot` actually produces a component-plus-residual plot. For normal-error models with constant weights and one covariate, this amounts to a plot of the observations with the fitted line inscribed. For other normal-error models, weighted residuals are calculated and added to the fitted values.

For models with additional covariates, the line is the partial linear predictor for the variable in question ($xvar_1$ or a covariate) and includes the intercept β_0.

For generalized linear and Cox models, the fitted values are plotted on the scale of the "index" (linear predictor). Deviance residuals are added to the (partial) linear predictor to give component-plus-residual values. These values are plotted as small circles.

See [R] **fracpoly** for examples using `fracplot`.

Methods and formulas

All postestimation commands listed above and `fracplot` and `fracpred` are implemented as ado-files.

See *Methods and formulas* in [R] **fracpoly** for notation.

The component-plus-residual values graphed by `fracplot` are calculated as follows: Let the data consist of triplets $(y_i, x_i, \mathbf{z}_i)$, $i = 1, \ldots, n$, where $\mathbf{z}_i$ is the vector of covariates for the ith observation, after applying possible fractional polynomial transformation and adjustment as described earlier. Let $\widehat{\eta}_i = \widehat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \widehat{\boldsymbol{\beta}} + \mathbf{z}_i' \widehat{\boldsymbol{\gamma}}$ be the linear predictor from the FP model, as given by the `fracpred` command or, equivalently, by the `predict` command with the `xb` option, following `fracpoly`. Here $\mathbf{H}(x_i) = \{H_1(x_i), \ldots, H_m(x_i)\}'$ is the vector of FP functions described above, $\mathbf{H}(x_0) = \{H_1(x_0), \ldots, H_m(x_0)\}'$ is the vector of adjustments to x_0 (often, x_0 is chosen to be the mean of the x_i), $\widehat{\boldsymbol{\beta}}$ is the estimated parameter vector, and $\widehat{\boldsymbol{\gamma}}$ is the estimated parameter vector for the covariates. The values $\widehat{\eta}_i^* = \widehat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \widehat{\boldsymbol{\beta}}$ represent the behavior of the FP model for x at fixed values $\mathbf{z} = \mathbf{0}$ of the (adjusted) covariates. The ith component-plus-residual is defined as $\widehat{\eta}_i^* + d_i$, where d_i is the deviance residual for the ith observation. For normal-errors models, $d_i = \sqrt{w_i}(y_i - \widehat{\eta}_i)$, where w_i is the case weight (or 1, if *weight* is not specified). For logistic, Cox, and generalized linear regression models, see [R] **logistic**, [R] **probit**, [ST] **stcox**, and [R] **glm** for the formula for d_i. The formula for `poisson` models is the same as that for `glm` with `family(poisson)`. For `stcox`, d_i is the partial martingale residual (see [ST] **stcox postestimation**).

`fracplot` plots the values of d_i and the curve represented by $\widehat{\eta}_i^*$ against x_i. The confidence interval for $\widehat{\eta}_i^*$ is obtained from the variance–covariance matrix of the entire model and takes into account the uncertainty in estimating β_0, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$ (but not in estimating the FP powers for x).

`fracpred` with the `for(`*varname*`)` option calculates the predicted index at $x_i = x_0$ and $\mathbf{z}_i = \mathbf{0}$; that is, $\widehat{\eta}_i = \widehat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \widehat{\boldsymbol{\beta}}$. The standard error is calculated from the variance–covariance matrix of $(\widehat{\beta}_0, \widehat{\boldsymbol{\beta}})$, again ignoring estimation of the powers.

Acknowledgment

`fracplot` and `fracpred` were written by Patrick Royston of the MRC Clinical Trials Unit, London.

frontier — Stochastic frontier models

Syntax

```
frontier depvar [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
distribution(hnormal)	half-normal distribution for the inefficiency term
distribution(exponential)	exponential distribution for the inefficiency term
distribution(tnormal)	truncated-normal distribution for the inefficiency term
ufrom(*matrix*)	specify untransformed log likelihood; only with d(tnormal)
cm(*varlist* [, noconstant])	fit conditional mean model; only with d(tnormal); use noconstant to suppress constant term
Model 2	
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
uhet(*varlist* [, noconstant])	explanatory variables for technical inefficiency variance function; use noconstant to suppress constant term
vhet(*varlist* [, noconstant])	explanatory variables for idiosyncratic error variance function; use noconstant to suppress constant term
cost	fit cost frontier model; default is production frontier model
SE	
vce(*vcetype*)	*vcetype* may be oim, opg, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

indepvars and *varlist* may contain factor variables; see [U] **11.4.3 Factor variables**.
bootstrap, by, jackknife, rolling, and statsby are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Frontier models

Description

`frontier` fits stochastic production or cost frontier models; the default is a production frontier model. It provides estimators for the parameters of a linear model with a disturbance that is assumed to be a mixture of two components, which have a strictly nonnegative and symmetric distribution, respectively. `frontier` can fit models in which the nonnegative distribution component (a measurement of inefficiency) is assumed to be from a half-normal, exponential, or truncated-normal distribution. See Kumbhakar and Lovell (2000) for a detailed introduction to frontier analysis.

Options

Model

`noconstant`; see [R] **estimation options**.

`distribution(`*distname*`)` specifies the distribution for the inefficiency term as half-normal (`hnormal`), `exponential`, or truncated-normal (`tnormal`). The default is `hnormal`.

`ufrom(`*matrix*`)` specifies a $1 \times K$ matrix of untransformed starting values when the distribution is truncated-normal (`tnormal`). `frontier` can estimate the parameters of the model by maximizing either the log likelihood or a transformed log likelihood (see *Methods and formulas*). `frontier` automatically transforms the starting values before passing them on to the transformed log likelihood. The matrix must have the same number of columns as there are parameters to estimate.

`cm(`*varlist* [`, noconstant`]`)` may be used only with `distribution(tnormal)`. Here `frontier` will fit a conditional mean model in which the mean of the truncated-normal distribution is modeled as a linear function of the set of covariates specified in *varlist*. Specifying `noconstant` suppresses the constant in the mean function.

Model 2

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

By default, when fitting the truncated-normal model or the conditional mean model, `frontier` maximizes a transformed log likelihood. When constraints are applied, `frontier` will maximize the untransformed log likelihood with constraints defined in the untransformed metric.

`uhet(`*varlist*[`, noconstant`]`)` specifies that the technical inefficiency component is heteroskedastic, with the variance function depending on a linear combination of $varlist_u$. Specifying `noconstant` suppresses the constant term from the variance function. This option may not be specified with `distribution(tnormal)`.

`vhet(`*varlist*[`, noconstant`]`)` specifies that the idiosyncratic error component is heteroskedastic, with the variance function depending on a linear combination of $varlist_v$. Specifying `noconstant` suppresses the constant term from the variance function. This option may not be specified with `distribution(tnormal)`.

`cost` specifies that `frontier` fit a cost frontier model.

SE

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `frontier` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Stochastic production frontier models were introduced by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Since then, stochastic frontier models have become a popular subfield in econometrics. Kumbhakar and Lovell (2000) provide a good introduction.

`frontier` fits three stochastic frontier models with distinct parameterizations of the inefficiency term and can fit stochastic production or cost frontier models.

Let's review the nature of the stochastic frontier problem. Suppose that a producer has a production function $f(\mathbf{z}_i, \beta)$. In a world without error or inefficiency, the ith firm would produce

$$q_i = f(\mathbf{z}_i, \beta)$$

Stochastic frontier analysis assumes that each firm potentially produces less than it might due to a degree of inefficiency. Specifically,

$$q_i = f(\mathbf{z}_i, \beta)\xi_i$$

where ξ_i is the level of efficiency for firm i; ξ_i must be in the interval $(0, 1]$. If $\xi_i = 1$, the firm is achieving the optimal output with the technology embodied in the production function $f(\mathbf{z}_i, \beta)$. When $\xi_i < 1$, the firm is not making the most of the inputs $\mathbf{z}_i$ given the technology embodied in the production function $f(\mathbf{z}_i, \beta)$. Because the output is assumed to be strictly positive (that is, $q_i > 0$), the degree of technical efficiency is assumed to be strictly positive (that is, $\xi_i > 0$).

Output is also assumed to be subject to random shocks, implying that

$$q_i = f(\mathbf{z}_i, \beta)\xi_i \exp(v_i)$$

Taking the natural log of both sides yields

$$\ln(q_i) = \ln\{f(\mathbf{z}_i, \beta)\} + \ln(\xi_i) + v_i$$

Assuming that there are k inputs and that the production function is linear in logs, defining $u_i = -\ln(\xi_i)$ yields

$$\ln(q_i) = \beta_0 + \sum_{j=1}^{k} \beta_j \ln(z_{ji}) + v_i - u_i \tag{1}$$

Because u_i is subtracted from $\ln(q_i)$, restricting $u_i \geq 0$ implies that $0 < \xi_i \leq 1$, as specified above.

Kumbhakar and Lovell (2000) provide a detailed version of the above derivation, and they show that performing an analogous derivation in the dual cost function problem allows us to specify the problem as

$$\ln(c_i) = \beta_0 + \beta_q \ln(q_i) + \sum_{j=1}^{k} \beta_j \ln(p_{ji}) + v_i + u_i \tag{2}$$

where q_i is output, z_{ji} are input quantities, c_i is cost, and the p_{ji} are input prices.

Intuitively, the inefficiency effect is required to lower output or raise expenditure, depending on the specification.

❑ Technical note

The model that `frontier` actually fits is of the form

$$y_i = \beta_0 + \sum_{j=1}^{k} \beta_j x_{ji} + v_i - s u_i$$

where

$$s = \begin{cases} 1, & \text{for production functions} \\ -1, & \text{for cost functions} \end{cases}$$

so, in the context of the discussion above, $y_i = \ln(q_i)$, and $x_{ji} = \ln(z_{ji})$ for a production function; and for a cost function, $y_i = \ln(c_i)$, and the x_{ji} are the $\ln(p_{ji})$ and $\ln(q_i)$. You must take the natural logarithm of the data before fitting a stochastic frontier production or cost model. `frontier` performs no transformations on the data.

❑

Different specifications of the u_i and the v_i terms give rise to distinct models. `frontier` provides estimators for the parameters of three basic models in which the idiosyncratic component, v_i, is assumed to be independently $N(0, \sigma_v)$ distributed over the observations. The basic models differ in their specification of the inefficiency term, u_i, as follows:

`exponential`: the u_i are independently exponentially distributed with variance σ_u^2

`hnormal`: the u_i are independently half-normally $N^+(0, \sigma_u^2)$ distributed

`tnormal`: the u_i are independently $N^+(\mu, \sigma_u^2)$ distributed with truncation point at 0

For half-normal or exponential distributions, `frontier` can fit models with heteroskedastic error components, conditional on a set of covariates. For a truncated-normal distribution, `frontier` can also fit a conditional mean model in which the mean is modeled as a linear function of a set of covariates.

▷ Example 1

For our first example, we demonstrate the half-normal and exponential models by reproducing a study found in Greene (2003, 505), which uses data originally published in Zellner and Revankar (1969). In this study of the transportation-equipment manufacturing industry, observations on value added, capital, and labor are used to estimate a Cobb–Douglas production function. The variable `lnv` is the log-transformed value added, `lnk` is the log-transformed capital, and `lnl` is the log-transformed labor. OLS estimates are compared with those from stochastic frontier models using both the half-normal and exponential distribution for the inefficiency term.

The parameter estimates and the estimates of the inefficiency terms closely match those published in Greene (2003, 505), but the standard errors of the parameter estimates are estimated differently (see the technical note below).

The output from `frontier` includes estimates of the standard deviations of the two error components, σ_v and σ_u, which are labeled `sigma_v` and `sigma_u`, respectively. In the log likelihood, they are parameterized as $\ln\sigma_v^2$ and $\ln\sigma_u^2$, and these estimates are labeled `/lnsig2v` and `/lnsig2u` in the output. `frontier` also reports two other useful parameterizations. The estimate of the total error variance, $\sigma_S^2 = \sigma_v^2 + \sigma_u^2$, is labeled `sigma2`, and the estimate of the ratio of the standard deviation of the inefficiency component to the standard deviation of the idiosyncratic component, $\lambda = \sigma_u/\sigma_v$, is labeled `lambda`.

At the bottom of the output, `frontier` reports the results of a test that there is no technical inefficiency component in the model. This is a test of the null hypothesis $H_0 : \sigma_u^2 = 0$ against the alternative hypotheses $H_1 : \sigma_u^2 > 0$. If the null hypothesis is true, the stochastic frontier model reduces to an OLS model with normal errors. However, because the test lies on the boundary of the parameter space of σ_u^2, the standard likelihood-ratio test is not valid, and a one-sided generalized likelihood-ratio test must be constructed; see Gutierrez, Carter, and Drukker (2001). For this example, the output shows LR = 0.43 with a p-value of 0.256 for the half-normal model and LR = 1.21 with a p-value of 0.135 for the exponential model. There are several possible reasons for the failure to reject the null hypothesis, but the fact that the test is based on an asymptotic distribution and the sample size was 25 is certainly a leading candidate among those possibilities.

◁

❑ Technical note

`frontier` maximizes the log-likelihood function of a stochastic frontier model by using the Newton–Raphson method, and the estimated variance–covariance matrix is calculated as the inverse of the negative Hessian (matrix of second partial derivatives); see [R] **ml**. When comparing the results with those published using other software, be aware of the difference in the optimization methods, which may result in different, yet asymptotically equivalent, variance estimates.

❑

▷ Example 2

Often the error terms may not have constant variance. `frontier` allows you to model heteroskedasticity in either error term as a linear function of a set of covariates. The variance of either the technical inefficiency or the idiosyncratic component may be modeled as

$$\sigma_i^2 = \exp(\mathbf{w}_i\boldsymbol{\delta})$$

The default constant included in $\mathbf{w}_i$ may be suppressed by appending a `noconstant` option to the list of covariates. Also, you can simultaneously specify covariates for both σ_{u_i} and σ_{v_i}.

In the example below, we use a sample of 756 observations of fictional firms producing a manufactured good by using capital and labor. The firms are hypothesized to use a constant returns-to-scale technology, but the sizes of the firms differ. Believing that this size variation will introduce heteroskedasticity into the idiosyncratic error term, we estimate the parameters of a Cobb–Douglas production function. To do this, we use a conditional heteroskedastic half-normal model, with the size of the firm as an explanatory variable in the variance function for the idiosyncratic error. We also perform a test of the hypothesis that the firms use a constant returns-to-scale technology.

```

           chi2(  1) =    0.03
         Prob > chi2 =    0.8622
```

The output above indicates that the variance of the idiosyncratic error term is a function of firm size. Also, we failed to reject the hypothesis that the firms use a constant returns-to-scale technology.

◁

❑ Technical note

In small samples, the conditional heteroskedastic estimators will lack precision for the variance parameters and may fail to converge altogether.

❑

▷ Example 3

Let's turn our attention to the truncated-normal model. Once again, we will use fictional data. For this example, we have 1,231 observations on the quantity of output, the total cost of production for each firm, the prices that each firm paid for labor and capital services, and a categorical variable measuring the quality of each firm's management. After taking the natural logarithm of the costs (`lncost`), prices (`lnp_k` and `lnp_l`), and output (`lnout`), we fit a stochastic cost frontier model and specify the distribution for the inefficiency term to be truncated normal.

```
. use http://www.stata-press.com/data/r12/frontier2

```
H0: No inefficiency component:            z =   5.595          Prob>=z = 0.000
```

In addition to the coefficients, the output reports estimates for several parameters. `sigma_v2` is the estimate of σ_v^2. `sigma_u2` is the estimate of σ_u^2. `gamma` is the estimate of $\gamma = \sigma_u^2/\sigma_S^2$. `sigma2` is the estimate of $\sigma_S^2 = \sigma_v^2 + \sigma_u^2$. Because γ must be between 0 and 1, the optimization is parameterized in terms of the inverse logit of γ, and this estimate is reported as `ilgtgamma`. Because σ_S^2 must be positive, the optimization is parameterized in terms of $\ln(\sigma_S^2)$, whose estimate is reported as `lnsigma2`. Finally, `mu` is the estimate of μ, the mean of the truncated-normal distribution.

In the output above, the generalized log-likelihood test for the presence of the inefficiency term has been replaced with a test based on the third moment of the OLS residuals. When $\mu = 0$ and $\sigma_u = 0$, the truncated-normal model reduces to a linear regression model with normally distributed errors. However, the distribution of the test statistic under the null hypothesis is not well established, because it becomes impossible to evaluate the log likelihood as σ_u approaches zero, prohibiting the use of the likelihood-ratio test.

However, Coelli (1995) noted that the presence of an inefficiency term would negatively skew the residuals from an OLS regression. By identifying negative skewness in the residuals with the presence of an inefficiency term, Coelli derived a one-sided test for the presence of the inefficiency term. The results of this test are given at the bottom of the output. For this example, the null hypothesis of no inefficiency component is rejected.

In the example below, we fit a truncated model and detect a statistically significant inefficiency term in the model. We might question whether the inefficiency term is identically distributed over all firms or whether there might be heterogeneity across firms. `frontier` provides an extension to the truncated normal model by allowing the mean of the inefficiency term to be modeled as a linear function of a set of covariates. In our dataset, we have a categorical variable that measures the quality of a firm's management. We refit the model, including the `cm()` option, specifying a set of

binary indicator variables representing the different categories of the quality-measurement variable as covariates.

Methods and formulas

frontier is implemented as an ado-file.

Consider an equation of the form

$$y_i = \mathbf{x}_i\boldsymbol{\beta} + v_i - su_i$$

where y_i is the dependent variable, $\mathbf{x}_i$ is a $1 \times k$ vector of observations on the independent variables included as indent covariates, $\boldsymbol{\beta}$ is a $k \times 1$ vector of coefficients, and

$$s = \begin{cases} 1, & \text{for production functions} \\ -1, & \text{for cost functions} \end{cases}$$

The log-likelihood functions are as follows.

Normal/half-normal model:

$$\ln L = \sum_{i=1}^{N} \left\{ \frac{1}{2}\ln\left(\frac{2}{\pi}\right) - \ln\sigma_S + \ln\Phi\left(-\frac{s\epsilon_i\lambda}{\sigma_S}\right) - \frac{\epsilon_i^2}{2\sigma_S^2} \right\}$$

Normal/exponential model:

$$\ln L = \sum_{i=1}^{N} \left\{ -\ln\sigma_u + \frac{\sigma_v^2}{2\sigma_u^2} + \ln\Phi\left(\frac{-s\epsilon_i - \frac{\sigma_v^2}{\sigma_u}}{\sigma_v}\right) + \frac{s\epsilon_i}{\sigma_u} \right\}$$

Normal/truncated-normal model:

$$\ln L = \sum_{i=1}^{N} \left\{ -\frac{1}{2}\ln(2\pi) - \ln\sigma_S - \ln\Phi\left(\frac{\mu}{\sigma_S\sqrt{\gamma}}\right) + \ln\Phi\left[\frac{(1-\gamma)\mu - s\gamma\epsilon_i}{\{\sigma_S^2\gamma(1-\gamma)\}^{1/2}}\right] - \frac{1}{2}\left(\frac{\epsilon_i + s\mu}{\sigma_S}\right)^2 \right\}$$

where $\sigma_S = (\sigma_u^2 + \sigma_v^2)^{1/2}$, $\lambda = \sigma_u/\sigma_v$, $\gamma = \sigma_u^2/\sigma_S^2$, $\epsilon_i = y_i - \mathbf{x}_i\boldsymbol{\beta}$, and $\Phi()$ is the cumulative distribution function of the standard normal distribution.

To obtain estimation for u_i, you can use either the mean or the mode of the conditional distribution $f(u|\epsilon)$.

$$E\left(u_i \mid \epsilon_i\right) = \mu_{*i} + \sigma_* \left\{ \frac{\phi(-\mu_{*i}/\sigma_*)}{\Phi(\mu_{*i}/\sigma_*)} \right\}$$

$$M\left(u_i \mid \epsilon_i\right) = \begin{cases} \mu_{*i}, & \text{if } \mu_{*i} \geq 0 \\ 0, & \text{otherwise} \end{cases}$$

Then the technical efficiency ($s = 1$) or cost efficiency ($s = -1$) will be estimated by

$$\begin{aligned} E_i &= E\left\{\exp(-su_i) \mid \epsilon_i\right\} \\ &= \left\{ \frac{1 - \Phi\left(s\sigma_* - \mu_{*i}/\sigma_*\right)}{1 - \Phi\left(-\mu_{*i}/\sigma_*\right)} \right\} \exp\left(-s\mu_{*i} + \frac{1}{2}\sigma_*^2 \right) \end{aligned}$$

where μ_{*i} and σ_* are defined for the normal/half-normal model as

$$\mu_{*i} = -s\epsilon_i\sigma_u^2/\sigma_S^2$$
$$\sigma_* = \sigma_u\sigma_v/\sigma_S$$

for the normal/exponential model as

$$\mu_{*i} = -s\epsilon_i - \sigma_v^2/\sigma_u$$
$$\sigma_* = \sigma_v$$

and for the normal/truncated-normal model as

$$\mu_{*i} = \frac{-s\epsilon_i\sigma_u^2 + \mu\sigma_v^2}{\sigma_S^2}$$
$$\sigma_* = \sigma_u\sigma_v/\sigma_S$$

In the half-normal and exponential models, when heteroskedasticity is assumed, the standard deviations, σ_u or σ_v, will be replaced in the above equations by

$$\sigma_i^2 = \exp(\mathbf{w}_i\boldsymbol{\delta})$$

where $\mathbf{w}$ is the vector of explanatory variables in the variance function.

In the conditional mean model, the mean parameter of the truncated normal distribution, μ, is modeled as a linear combination of the set of covariates, $\mathbf{w}$.

$$\mu = \mathbf{w}_i\boldsymbol{\delta}$$

Therefore, the log-likelihood function can be rewritten as

$$\ln L = \sum_{i=1}^{N}\left[-\frac{1}{2}\ln(2\pi) - \ln\sigma_S - \ln\Phi\left(\frac{\mathbf{w}_i\boldsymbol{\delta}}{\sqrt{\sigma_S^2\gamma}}\right) + \ln\Phi\left\{\frac{(1-\gamma)\,\mathbf{w}_i\boldsymbol{\delta} - s\gamma\epsilon_i}{\sqrt{\sigma_S^2\gamma\,(1-\gamma)}}\right\} - \frac{1}{2}\left(\frac{\epsilon_i + s\mathbf{w}_i\boldsymbol{\delta}}{\sigma_S}\right)^2\right]$$

The z test reported in the output of the truncated-normal model is a third-moment test developed by Coelli (1995) as an extension of a test previously developed by Pagan and Hall (1983). Coelli shows that under the null of normally distributed errors, the statistic

$$z = \frac{m_3}{\left(\frac{6m_2^3}{N}\right)^{1/2}}$$

has a standard normal distribution, where m_3 is the third moment from the OLS regression. Because the residuals are either negatively skewed (production function) or positively skewed (cost function), a one-sided p-value is used.

Title

frontier postestimation — Postestimation tools for frontier

Description

The following postestimation commands are available after `frontier`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]

predict [type] { stub* | newvar_xb newvar_v newvar_u } [if] [in], scores
```

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the prediction
`u`	estimates of minus the natural log of the technical efficiency via $E(u_i \mid \epsilon_i)$
`m`	estimates of minus the natural log of the technical efficiency via $M(u_i \mid \epsilon_i)$
`te`	estimates of the technical efficiency via $E\{\exp(-su_i) \mid \epsilon_i\}$

$$s = \begin{cases} 1, & \text{for production functions} \\ -1, & \text{for cost functions} \end{cases}$$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`u` produces estimates of minus the natural log of the technical efficiency via $E(u_i \mid \epsilon_i)$.

`m` produces estimates of minus the natural log of the technical efficiency via $M(u_i \mid \epsilon_i)$.

`te` produces estimates of the technical efficiency via $E\{\exp(-su_i) \mid \epsilon_i\}$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_i\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\texttt{lnsig2v})$.

The third new variable will contain $\partial \ln L/\partial(\texttt{lnsig2u})$.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

fvrevar — Factor-variables operator programming command

Syntax

`fvrevar` [*varlist*] [*if*] [*in*] [`,` `substitute` `tsonly` `list` `stub(`*stub*`)`]

You must `tsset` your data before using `fvrevar` if *varlist* contains time-series operators; see [TS] **tset**.

Description

`fvrevar` creates an equivalent, temporary variable list for a *varlist* that might contain factor variables, interactions, or time-series–operated variables so that the resulting variable list can be used by commands that do not otherwise support factor variables or time-series–operated variables. The resulting list also could be used in a program to speed execution at the cost of using more memory.

Options

`substitute` specifies that equivalent, temporary variables be substituted for any factor variables, interactions, or time-series–operated variables in *varlist*. `substitute` is the default action taken by `fvrevar`; you do not need to specify the option.

`tsonly` specifies that equivalent, temporary variables be substituted for only the time-series–operated variables in *varlist*.

`list` specifies that all factor-variable operators and time-series operators be removed from *varlist* and the resulting list of base variables be returned in `r(varlist)`. No new variables are created with this option.

`stub(`*stub*`)` specifies that `fvrevar` generate named variables instead of temporary variables. The new variables will be named *stub#*.

Remarks

`fvrevar` might create no new variables, one new variable, or many new variables, depending on the number of factor variables, interactions, and time-series operators appearing in *varlist*. Any new variables created are temporary. The new, equivalent varlist is returned in `r(varlist)`. The new varlist corresponds one to one with the original *varlist*.

▷ Example 1

Typing

```
. use http://www.stata-press.com/data/r12/auto
. fvrevar i.rep78 mpg turn
```

creates five temporary variables corresponding to the levels of `rep78`. No new variables are created for variables `mpg` and `turn` because they do not contain factor-variable or time-series operators.

The resulting variable list is

```
. display "`r(varlist)'"
__000000 __000001 __000002 __000003 __000004  mpg turn
```

(Your temporary variable names may be different, but that is of no consequence.)

Temporary variables automatically vanish when the program concludes.

◁

▷ Example 2

Suppose we want to create temporary variables for specific levels of a factor variable. To do this, we can use the parenthesis notation of factor-variable syntax.

```
. fvrevar i(2,3)bn.rep78 mpg
```

creates two temporary variables corresponding to levels 2 and 3 of `rep78`. Notice that we specified that neither level 2 nor 3 be set as the base level by using the `bn` notation. If we did not specify `bn`, level 2 would have been treated as the base level.

The resulting variable list is

```
. display "‘r(varlist)’"
__00000E __00000F mpg
```

We can see the results by listing the new variables alongside the original value of `rep78`.

```
. list rep78 ‘r(varlist)’  in 1/5
```

	rep78	__00000E	__00000F	mpg
1.	3	1	0	22
2.	3	1	0	17
3.	.	.	.	22
4.	3	1	0	20
5.	4	0	1	15

If we had needed only the base-variable names, we could have specified

```
. fvrevar i(2,3)bn.rep78 mpg, list
. display "‘r(varlist)’"
mpg rep78
```

The order of the list will probably differ from that of the original list; base variables are listed only once.

◁

▷ Example 3

Now let's assume we have a *varlist* containing both an interaction and time-series–operated variables. If we want to create temporary variables for the entire equivalent *varlist*, we can specify `fvrevar` with no options.

```
. generate t = _n
. tsset t
. fvrevar c.turn#i(2,3).rep78 L.mpg
```

The resulting variable list is

```
. display "‘r(varlist)’"
__00000I __00000K __00000M
```

If we want to create temporary variables only for the time-series–operated variables, we can specify the `tsonly` option.

```
. fvrevar c.turn#i(2,3).rep78 L.mpg, tsonly
```

The resulting variable list is

```
. display "`r(varlist)'"
2b.rep78#c.turn 3.rep78#c.turn __00000M
```

Notice that `fvrevar` returned the expanded factor-variable list with the `tsonly` option.

◁

❑ Technical note

`fvrevar, substitute` avoids creating duplicate variables. Consider

```
. fvrevar i.rep78 turn mpg i.rep78
```

`i.rep78` appears twice in the varlist. `fvrevar` will create only one set of new variables for the five levels of `rep78` and will use these new variables once in the resulting `r(varlist)`. Moreover, `fvrevar` will do this even across multiple calls:

```
. fvrevar i.rep78 turn mpg
. fvrevar i.rep78
```

`i.rep78` appears in two separate calls. At the first call, `fvrevar` creates five temporary variables corresponding to the five levels of `rep78`. At the second call, `fvrevar` remembers what it has done and uses the same temporary variables for `i.rep78`.

❑

Saved results

`fvrevar` saves the following in `r()`:

Macros

`r(varlist)`	the modified variable list or list of base-variable names

Title

fvset — Declare factor-variable settings

Syntax

Declare base settings

```
fvset base base_spec varlist
```

Declare design settings

```
fvset design design_spec varlist
```

Clear the current settings

```
fvset clear varlist
```

Report the current settings

```
fvset report [varlist] [, base(base_spec) design(design_spec)]
```

base_spec	Description
`default`	default base
`first`	lowest level value; the default
`last`	highest level value
`frequent`	most frequent level value
`none`	no base
#	nonnegative integer value

design_spec	Description
`default`	default base
`asbalanced`	accumulate using $1/k$, k = number of levels
`asobserved`	accumulate using observed relative frequencies; the default

Description

`fvset` declares factor-variable settings. Factor-variable settings identify the base level and how to accumulate statistics over levels.

`fvset base` specifies the base level for each variable in *varlist*. The default for factor variables without a declared base level is `first`.

`fvset design` specifies how to accumulate over the levels of a factor variable. The `margins` command is the only command aware of this setting; see [R] **margins**. By default, `margins` assumes that factor variables are `asobserved`, meaning that they are accumulated by weighting by the number of observations or the sum of the weights if weights have been specified.

`fvset clear` removes factor-variable settings for each variable in *varlist*. `fvset clear _all` removes all factor-variable settings from all variables.

`fvset report` reports the current factor-variable settings for each variable in *varlist*. `fvset` without arguments is a synonym for `fvset report`.

Options

`base(`*base_spec*`)` restricts `fvset report` to report only the factor-variable settings for variables with the specified *base_spec*.

`design(`*design_spec*`)` restricts `fvset report` to report only the factor-variable settings for variables with the specified *design_spec*.

Remarks

▷ Example 1

Using our `auto` dataset, we include factor variable `i.rep78` in a regression:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg i.rep78, baselevels
```

Source	SS	df	MS		
Model	549.415777	4	137.353944	Number of obs	= 69
Residual	1790.78712	64	27.9810488	F(4, 64)	= 4.91
				Prob > F	= 0.0016
Total	2340.2029	68	34.4147485	R-squared	= 0.2348
				Adj R-squared	= 0.1869
				Root MSE	= 5.2897

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
rep78						
1	0	(base)				
2	-1.875	4.181884	-0.45	0.655	-10.22927	6.479274
3	-1.566667	3.863059	-0.41	0.686	-9.284014	6.150681
4	.6666667	3.942718	0.17	0.866	-7.209818	8.543152
5	6.363636	4.066234	1.56	0.123	-1.759599	14.48687
_cons	21	3.740391	5.61	0.000	13.52771	28.47229

We specified the `baselevels` option so that the base level would be included in the output. By default, the first level is the base level. We can change the base level to `2`:

```
. fvset base 2 rep78
. regress mpg i.rep78, baselevels
```

Source	SS	df	MS	Number of obs =	69
				F(4, 64) =	4.91
Model	549.415777	4	137.353944	Prob > F =	0.0016
Residual	1790.78712	64	27.9810488	R-squared =	0.2348
				Adj R-squared =	0.1869
Total	2340.2029	68	34.4147485	Root MSE =	5.2897

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
rep78						
1	1.875	4.181884	0.45	0.655	-6.479274	10.22927
2	0	(base)				
3	.3083333	2.104836	0.15	0.884	-3.896559	4.513226
4	2.541667	2.247695	1.13	0.262	-1.948621	7.031954
5	8.238636	2.457918	3.35	0.001	3.32838	13.14889
_cons	19.125	1.870195	10.23	0.000	15.38886	22.86114

Let's set `rep78` to have no base level and fit a cell-means regression:

```
. fvset base none rep78
. regress mpg i.rep78, noconstant
```

Source	SS	df	MS	Number of obs =	69
				F(5, 64) =	227.47
Model	31824.2129	5	6364.84258	Prob > F =	0.0000
Residual	1790.78712	64	27.9810488	R-squared =	0.9467
				Adj R-squared =	0.9426
Total	33615	69	487.173913	Root MSE =	5.2897

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
rep78

5	27.36364	1.594908	17.16	0.000	24.17744	30.54983

◁

▷ Example 2

By default, `margins` accumulates a margin by using the observed relative frequencies of the factor levels.

```
. regress mpg i.foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =   13.18
       Model |  378.153515     1  378.153515            Prob > F      =  0.0005
    Residual |  2065.30594    72  28.6848048            R-squared     =  0.1548
-------------+------------------------------           Adj R-squared =  0.1430
       Total |  2443.45946    73  33.4720474            Root MSE      =  5.3558

------------------------------------------------------------------------------
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   1.foreign |    4.945804   1.362162     3.63   0.001     2.230384    7.661225
       _cons |    19.82692   .7427186    26.70   0.000     18.34634    21.30751
------------------------------------------------------------------------------

. margins
Predictive margins                                Number of obs   =         74
Model VCE    : OLS

Expression   : Linear prediction, predict()

------------------------------------------------------------------------------
             |            Delta-method
             |     Margin   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       _cons |    21.2973   .6226014    34.21   0.000     20.07702    22.51757
------------------------------------------------------------------------------
```

Let's set `foreign` to always accumulate using equal relative frequencies:

```
. fvset design asbalanced foreign
. regress mpg i.foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =   13.18
       Model |  378.153515     1  378.153515            Prob > F      =  0.0005
    Residual |  2065.30594    72  28.6848048            R-squared     =  0.1548
-------------+------------------------------           Adj R-squared =  0.1430
       Total |  2443.45946    73  33.4720474            Root MSE      =  5.3558

------------------------------------------------------------------------------
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   1.foreign |    4.945804   1.362162     3.63   0.001     2.230384    7.661225
       _cons |    19.82692   .7427186    26.70   0.000     18.34634    21.30751
------------------------------------------------------------------------------

. margins
Adjusted predictions                              Number of obs   =         74
Model VCE    : OLS

Expression   : Linear prediction, predict()
at           : foreign          (asbalanced)

------------------------------------------------------------------------------
             |            Delta-method
             |     Margin   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       _cons |   22.29983   .6810811    32.74   0.000     20.96493    23.63472
------------------------------------------------------------------------------
```

Suppose that we issued the `fvset design` command earlier in our session and that we cannot remember which variables we set as `asbalanced`. We can retrieve this information by using the `fvset report` command:

```
. fvset report, design(asbalanced)
  Variable    Base    Design
  ------------------------------
  foreign             asbalanced
  ------------------------------
```

◁

❑ Technical note

`margins` is aware of a factor variable's design setting only through the estimation results it is working with. The design setting is stored by the estimation command; thus changing the design setting between the estimation command and `margins` will have no effect. For example, the output from the following two calls to `margins` yields the same results:

```
. fvset clear foreign
. regress mpg i.foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =   13.18

Title

gllamm — Generalized linear and latent mixed models

Description

GLLAMM stands for generalized linear latent and mixed models, and `gllamm` is a Stata command for fitting such models written by Sophia Rabe-Hesketh (University of California–Berkeley) as part of joint work with Anders Skrondal (Norwegian Institute of Public Health) and Andrew Pickles (University of Manchester).

Remarks

Generalized linear latent and mixed models are a class of multilevel latent variable models, where a latent variable is a factor or a random effect (intercept or coefficient), or a disturbance (residual). The `gllamm` command for fitting such models is not an official command of Stata; it has been independently developed by highly regarded authors and is itself highly regarded. You can learn more about `gllamm` by visiting http://www.gllamm.org.

`gllamm` is available from the Statistical Software Components (SSC) archive. To install, type

```
. ssc describe gllamm
. ssc install gllamm
```

If you later wish to uninstall `gllamm`, type `ado uninstall gllamm`.

glm — Generalized linear models

Syntax

`glm` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`family(`*familyname*`)`	distribution of *depvar*; default is `family(gaussian)`
`link(`*linkname*`)`	link function; default is canonical link for `family()` specified
Model 2	
`noconstant`	suppress constant term
`exposure(`*varname*`)`	include ln(*varname*) in model with coefficient constrained to 1
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
`mu(`*varname*`)`	use *varname* as the initial estimate for the mean of *depvar*
`init(`*varname*`)`	synonym for `mu(`*varname*`)`
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `eim`, `opg`, `bootstrap`, `jackknife`, `hac` *kernel*, `jackknife1`, or `unbiased`
`vfactor(#)`	multiply variance matrix by scalar #
`disp(#)`	quasilikelihood multiplier
`scale(x2 | dev | #)`	set the scale parameter
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`eform`	report exponentiated coefficients
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
`ml`	use maximum likelihood optimization; the default
`irls`	use iterated, reweighted least-squares optimization of the deviance
maximize_options	control the maximization process; seldom used
`fisher(#)`	use the Fisher scoring Hessian or expected information matrix (EIM)
`search`	search for good starting values
`noheader`	suppress header table from above coefficient table
`notable`	suppress coefficient table
`nodisplay`	suppress the output; iteration log is still displayed
`coeflegend`	display legend instead of statistics

familyname	Description
gaussian	Gaussian (normal)
igaussian	inverse Gaussian
binomial [*varname*$_N$ | #$_N$]	Bernoulli/binomial
poisson	Poisson
nbinomial [#$_k$ | ml]	negative binomial
gamma	gamma

linkname	Description
identity	identity
log	log
logit	logit
probit	probit
cloglog	cloglog
power #	power
opower #	odds power
nbinomial	negative binomial
loglog	log-log
logc	log-complement

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)`, `vce(jackknife)`, and `vce(jackknife1)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`vce()`, `vfactor()`, `disp()`, `scale()`, `irls`, `fisher()`, `noheader`, `notable`, `nodisplay`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`noheader`, `notable`, `nodisplay`, and `coeflegend` do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Generalized linear models > Generalized linear models (GLM)

Description

`glm` fits generalized linear models. It can fit models by using either IRLS (maximum quasilikelihood) or Newton–Raphson (maximum likelihood) optimization, which is the default.

See [I] **estimation commands** for a complete list of Stata's estimation commands, several of which fit models that can also be fit using `glm`.

Options

Model

`family(`*familyname*`)` specifies the distribution of *depvar*; `family(gaussian)` is the default.

`link(`*linkname*`)` specifies the link function; the default is the canonical link for the `family()` specified (except for `family(nbinomial)`).

Model 2

`noconstant`, `exposure(`*varname*`)`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**. `constraints(`*constraints*`)` and `collinear` are not allowed with `irls`.

`mu(`*varname*`)` specifies *varname* as the initial estimate for the mean of *depvar*. This option can be useful with models that experience convergence difficulties, such as `family(binomial)` models with power or odds-power links. `init(`*varname*`)` is a synonym.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

In addition to the standard *vcetype*s, `glm` allows the following alternatives:

`vce(eim)` specifies that the EIM estimate of variance be used.

`vce(jackknife1)` specifies that the one-step jackknife estimate of variance be used.

`vce(hac` *kernel* $[$*#*$]$`)` specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels built into `glm`. *kernel* is a user-written program or one of

`nwest` | `gallant` | `anderson`

specifies the number of lags. If *#* is not specified, $N-2$ is assumed. If you wish to specify `vce(hac ...)`, you must `tsset` your data before calling `glm`.

`vce(unbiased)` specifies that the unbiased sandwich estimate of variance be used.

`vfactor(#)` specifies a scalar by which to multiply the resulting variance matrix. This option allows you to match output with other packages, which may apply degrees of freedom or other small-sample corrections to estimates of variance.

`disp(#)` multiplies the variance of *depvar* by *#* and divides the deviance by *#*. The resulting distributions are members of the quasilikelihood family.

`scale(x2` | `dev` | `#)` overrides the default scale parameter. This option is allowed only with Hessian (information matrix) variance estimates.

By default, `scale(1)` is assumed for the discrete distributions (binomial, Poisson, and negative binomial), and `scale(x2)` is assumed for the continuous distributions (Gaussian, gamma, and inverse Gaussian).

`scale(x2)` specifies that the scale parameter be set to the Pearson chi-squared (or generalized chi-squared) statistic divided by the residual degrees of freedom, which is recommended by McCullagh and Nelder (1989) as a good general choice for continuous distributions.

scale(dev) sets the scale parameter to the deviance divided by the residual degrees of freedom. This option provides an alternative to scale(x2) for continuous distributions and overdispersed or underdispersed discrete distributions.

scale(#) sets the scale parameter to #. For example, using scale(1) in family(gamma) models results in exponential-errors regression. Additional use of link(log) rather than the default link(power -1) for family(gamma) essentially reproduces Stata's streg, dist(exp) nohr command (see [ST] **streg**) if all the observations are uncensored.

Reporting

level(#); see [R] **estimation options**.

eform displays the exponentiated coefficients and corresponding standard errors and confidence intervals. For family(binomial) link(logit) (that is, logistic regression), exponentiation results in odds ratios; for family(poisson) link(log) (that is, Poisson regression), exponentiated coefficients are rate ratios.

nocnsreport; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

ml requests that optimization be carried out using Stata's ml commands and is the default.

irls requests iterated, reweighted least-squares (IRLS) optimization of the deviance instead of Newton–Raphson optimization of the log likelihood. If the irls option is not specified, the optimization is carried out using Stata's ml commands, in which case all options of ml maximize are also available.

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default *vcetype* to vce(opg).

fisher(#) specifies the number of Newton–Raphson steps that should use the Fisher scoring Hessian or EIM before switching to the observed information matrix (OIM). This option is useful only for Newton–Raphson optimization (and not when using irls).

search specifies that the command search for good starting values. This option is useful only for Newton–Raphson optimization (and not when using irls).

The following options are available with glm but are not shown in the dialog box:

noheader suppresses the header information from the output. The coefficient table is still displayed.

notable suppresses the table of coefficients from the output. The header information is still displayed.

nodisplay suppresses the output. The iteration log is still displayed.

coeflegend; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

General use
Variance estimators
User-defined functions

General use

`glm` fits generalized linear models of y with covariates $\mathbf{x}$:

$$g\{E(y)\} = \mathbf{x}\boldsymbol{\beta}, \qquad y \sim F$$

$g(\,)$ is called the link function, and F is the distributional family. Substituting various definitions for $g(\,)$ and F results in a surprising array of models. For instance, if y is distributed as Gaussian (normal) and $g(\,)$ is the identity function, we have

$$E(y) = \mathbf{x}\boldsymbol{\beta}, \qquad y \sim \text{Normal}$$

or linear regression. If $g(\,)$ is the logit function and y is distributed as Bernoulli, we have

$$\text{logit}\{E(y)\} = \mathbf{x}\boldsymbol{\beta}, \qquad y \sim \text{Bernoulli}$$

or logistic regression. If $g(\,)$ is the natural log function and y is distributed as Poisson, we have

$$\ln\{E(y)\} = \mathbf{x}\boldsymbol{\beta}, \qquad y \sim \text{Poisson}$$

or Poisson regression, also known as the log-linear model. Other combinations are possible.

Although `glm` can be used to perform linear regression (and, in fact, does so by default), this regression should be viewed as an instructional feature; `regress` produces such estimates more quickly, and many postestimation commands are available to explore the adequacy of the fit; see [R] **regress** and [R] **regress postestimation**.

In any case, you specify the link function by using the `link()` option and specify the distributional family by using `family()`. The available link functions are

Link function	`glm` option
identity	`link(identity)`
log	`link(log)`
logit	`link(logit)`
probit	`link(probit)`
complementary log-log	`link(cloglog)`
odds power	`link(opower #)`
power	`link(power #)`
negative binomial	`link(nbinomial)`
log-log	`link(loglog)`
log-complement	`link(logc)`

Define $\mu = E(y)$ and $\eta = g(\mu)$, meaning that $g(\cdot)$ maps $E(y)$ to $\eta = \mathbf{x}\boldsymbol{\beta} + \text{offset}$.

Link functions are defined as follows:

`identity` is defined as $\eta = g(\mu) = \mu$.

`log` is defined as $\eta = \ln(\mu)$.

`logit` is defined as $\eta = \ln\{\mu/(1-\mu)\}$, the natural log of the odds.

`probit` is defined as $\eta = \Phi^{-1}(\mu)$, where $\Phi^{-1}(\,)$ is the inverse Gaussian cumulative.

`cloglog` is defined as $\eta = \ln\{-\ln(1-\mu)\}$.

`opower` is defined as $\eta = \left[\{\mu/(1-\mu)\}^n - 1\right]/n$, the power of the odds. The function is generalized so that `link(opower 0)` is equivalent to `link(logit)`, the natural log of the odds.

`power` is defined as $\eta = \mu^n$. Specifying `link(power 1)` is equivalent to specifying `link(identity)`. The power function is generalized so that $\mu^0 \equiv \ln(\mu)$. Thus `link(power 0)` is equivalent to `link(log)`. Negative powers are, of course, allowed.

`nbinomial` is defined as $\eta = \ln\{\mu/(\mu+k)\}$, where $k = 1$ if `family(nbinomial)` is specified, $k = \#_k$ if `family(nbinomial` $\#_k$`)` is specified, and k is estimated via maximum likelihood if `family(nbinomial ml)` is specified.

`loglog` is defined as $\eta = -\ln\{-\ln(\mu)\}$.

`logc` is defined as $\eta = \ln(1-\mu)$.

The available distributional families are

Family	`glm` option
Gaussian (normal)	`family(gaussian)`
inverse Gaussian	`family(igaussian)`
Bernoulli/binomial	`family(binomial)`
Poisson	`family(poisson)`
negative binomial	`family(nbinomial)`
gamma	`family(gamma)`

`family(normal)` is a synonym for `family(gaussian)`.

The binomial distribution can be specified as 1) `family(binomial)`, 2) `family(binomial` $\#_N$`)`, or 3) `family(binomial` *varname*$_N$`)`. In case 2, $\#_N$ is the value of the binomial denominator N, the number of trials. Specifying `family(binomial 1)` is the same as specifying `family(binomial)`. In case 3, *varname*$_N$ is the variable containing the binomial denominator, allowing the number of trials to vary across observations.

The negative binomial distribution can be specified as 1) `family(nbinomial)`, 2) `family(nbinomial` $\#_k$`)`, or 3) `family(nbinomial ml)`. Omitting $\#_k$ is equivalent to specifying `family(nbinomial 1)`. In case 3, the value of $\#_k$ is estimated via maximum likelihood. The value $\#_k$ enters the variance and deviance functions. Typical values range between 0.01 and 2; see the technical note below.

You do not have to specify both `family()` and `link()`; the default `link()` is the canonical link for the specified `family()` (except for `nbinomial`):

Family	Default link
`family(gaussian)`	`link(identity)`
`family(igaussian)`	`link(power -2)`
`family(binomial)`	`link(logit)`
`family(poisson)`	`link(log)`
`family(nbinomial)`	`link(log)`
`family(gamma)`	`link(power -1)`

If you specify both `family()` and `link()`, not all combinations make sense. You may choose from the following combinations:

	identity	log	logit	probit	cloglog	power	opower	nbinomial	loglog	logc
Gaussian	x	x				x				
inverse Gaussian	x	x				x				
binomial	x	x	x	x	x	x	x		x	x
Poisson	x	x				x				
negative binomial	x	x				x		x		
gamma	x	x				x				

❑ Technical note

Some `family()` and `link()` combinations result in models already fit by Stata. These are

`family()`	`link()`	Options	Equivalent Stata command
`gaussian`	`identity`	*nothing* | `irls` | `irls vce(oim)`	`regress`
`gaussian`	`identity`	`t(`*var*`) vce(hac nwest #) vfactor(`$\#_v$`)`	`newey, t(`*var*`) lag(#)` (see note 1)
`binomial`	`cloglog`	*nothing* | `irls vce(oim)`	`cloglog` (see note 2)
`binomial`	`probit`	*nothing* | `irls vce(oim)`	`probit` (see note 2)
`binomial`	`logit`	*nothing* | `irls` | `irls vce(oim)`	`logit` or `logistic` (see note 3)
`poisson`	`log`	*nothing* | `irls` | `irls vce(oim)`	`poisson` (see note 3)
`nbinomial`	`log`	*nothing* | `irls vce(oim)`	`nbreg` (see note 4)
`gamma`	`log`	`scale(1)`	`streg, dist(exp) nohr` (see note 5)

Notes:

1. The variance factor $\#_v$ should be set to $n/(n-k)$, where n is the number of observations and k the number of regressors. If the number of regressors is not specified, the estimated standard errors will, as a result, differ by this factor.

2. Because the link is not the canonical link for the binomial family, you must specify the `vce(oim)` option if using `irls` to get equivalent standard errors. If `irls` is used without `vce(oim)`, the regression coefficients will be the same but the standard errors will be only asymptotically equivalent. If no options are specified (*nothing*), `glm` will optimize using Newton–Raphson, making it equivalent to the other Stata command.

   See [R] **cloglog** and [R] **probit** for more details about these commands.

3. Because the canonical link is being used, the standard errors will be equivalent whether the EIM or the OIM estimator of variance is used.

4. Family negative binomial, log-link models—also known as negative binomial regression models—are used for data with an overdispersed Poisson distribution. Although `glm` can be used to fit such models, using Stata's maximum likelihood `nbreg` command is probably better. In the GLM approach, you specify `family(nbinomial #k)` and then search for a $\#_k$ that results in the deviance-based dispersion being 1. You can also specify `family(nbinomial ml)` to estimate $\#_k$ via maximum likelihood, which will report the same value returned from `nbreg`. However, `nbreg` also reports a confidence interval for it; see [R] **nbreg** and Rogers (1993). Of course, `glm` allows links other than `log`, and for those links, including the canonical `nbinomial` link, you will need to use `glm`.

5. `glm` can be used to estimate parameters from exponential regressions, but this method requires specifying `scale(1)`. However, censoring is not available. Censored exponential regression may be modeled using `glm` with `family(poisson)`. The log of the original response is entered into a Poisson model as an offset, whereas the new response is the censor variable. The result of such modeling is identical to the log relative hazard parameterization of `streg, dist(exp) nohr`. See [ST] **streg** for details about the `streg` command.

In general, where there is overlap between a capability of `glm` and that of some other Stata command, we recommend using the other Stata command. Our recommendation is not because of some inferiority of the GLM approach. Rather, those other commands, by being specialized, provide options and ancillary commands that are missing in the broader `glm` framework. Nevertheless, `glm` does produce the same answers where it should.

Special note. When equivalence is expected, for some datasets, you may still see very slight differences in the results, most often only in the later digits of the standard errors. When you compare `glm` output to an equivalent Stata command, these tiny discrepancies arise for many reasons:

a. `glm` uses a general methodology for starting values, whereas the equivalent Stata command may be more specialized in its treatment of starting values.

b. When using a canonical link, `glm, irls` should be equivalent to the maximum likelihood method of the equivalent Stata command, yet the convergence criterion is different (one is for deviance, the other for log likelihood). These discrepancies are easily resolved by adjusting one convergence criterion to correspond to the other.

c. When both `glm` and the equivalent Stata command use Newton–Raphson, small differences may still occur if the Stata command has a different default convergence criterion from that of `glm`. Adjusting the convergence criterion will resolve the difference. See [R] **ml** and [R] **maximize** for more details.

❑

▷ Example 1

In example 1 of [R] **logistic**, we fit a model based on data from a study of risk factors associated with low birthweight (Hosmer and Lemeshow 2000, 25). We can replicate the estimation by using `glm`:

```
. use http://www.stata-press.com/data/r12/lbw
(Hosmer & Lemeshow data)
. glm low age lwt i.race smoke ptl ht ui, family(binomial) link(logit)
Iteration 0:   log likelihood =  -101.0213
Iteration 1:   log likelihood = -100.72519
Iteration 2:   log likelihood =   -100.724
Iteration 3:   log likelihood =   -100.724
Generalized linear models                         No. of obs      =       189
Optimization     : ML                             Residual df     =       180
                                                  Scale parameter =         1
Deviance         =  201.4479911                   (1/df) Deviance =  1.119156
Pearson          =  182.0233425                   (1/df) Pearson  =  1.011241
Variance function: V(u) = u*(1-u)                 [Bernoulli]
Link function    : g(u) = ln(u/(1-u))             [Logit]
                                                  AIC             =    1.1611
Log likelihood   = -100.7239956                   BIC             = -742.0665

`glm`, by default, presents coefficient estimates, whereas `logistic` presents the exponentiated coefficients—the odds ratios. `glm`'s `eform` option reports exponentiated coefficients, and `glm`, like Stata's other estimation commands, replays results.

```
. glm, eform
Generalized linear models                         No. of obs      =        189

These results are the same as those reported in example 1 of [R] **logistic**.

Included in the output header are values for the Akaike (1973) information criterion (AIC) and the Bayesian information criterion (BIC) (Raftery 1995). Both are measures of model fit adjusted for the number of parameters that can be compared across models. In both cases, a smaller value generally indicates a better model fit. AIC is based on the log likelihood and thus is available only when Newton–Raphson optimization is used. BIC is based on the deviance and thus is always available. ◁

❑ Technical note

The values for AIC and BIC reported in the output after `glm` are different from those reported by `estat ic`:

```
. estat ic
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
.	189	.	-100.724	9	219.448	248.6237

Note: N=Obs used in calculating BIC; see **[R] BIC note**

There are various definitions of these information criteria (IC) in the literature; `glm` and `estat ic` use different definitions. `glm` bases its computation of the BIC on deviance, whereas `estat ic` uses the likelihood. Both `glm` and `estat ic` use the likelihood to compute the AIC; however, the AIC from `estat ic` is equal to N, the number of observations, times the AIC from `glm`. Refer to *Methods and formulas* in this entry and [R] **estat** for the references and formulas used by `glm` and `estat`, respectively, to compute AIC and BIC. Inferences based on comparison of IC values reported by `glm` for different GLM models will be equivalent to those based on comparison of IC values reported by `estat ic` after `glm`.

❑

▷ Example 2

We use data from an early insecticide experiment, given in Pregibon (1980). The variables are `ldose`, the log dose of insecticide; `n`, the number of flour beetles subjected to each dose; and `r`, the number killed.

```
. use http://www.stata-press.com/data/r12/ldose
. list, sep(4)
```

	ldose	n	r
1.	1.6907	59	6
2.	1.7242	60	13
3.	1.7552	62	18
4.	1.7842	56	28
5.	1.8113	63	52
6.	1.8369	59	53
7.	1.861	62	61
8.	1.8839	60	60

The aim of the analysis is to estimate a dose–response relationship between p, the proportion killed, and X, the log dose.

As a first attempt, we will formulate the model as a linear logistic regression of p on `ldose`; that is, we will take the logit of p and represent the dose–response curve as a straight line in X:

$$\ln\{p/(1-p)\} = \beta_0 + \beta_1 X$$

Because the data are grouped, we cannot use Stata's `logistic` command to fit the model. Stata does, however, already have a command for performing logistic regression on data organized in this way, so we could type

```
. blogit r n ldose
  (output omitted)
```

Instead, we will fit the model by using `glm`:

```
. glm r ldose, family(binomial n) link(logit)
Iteration 0:   log likelihood = -18.824848
Iteration 1:   log likelihood = -18.715271
Iteration 2:   log likelihood = -18.715123
Iteration 3:   log likelihood = -18.715123
Generalized linear models                         No. of obs      =         8
Optimization     : ML                             Residual df     =         6
                                                  Scale parameter =         1
Deviance         =  11.23220702                   (1/df) Deviance =  1.872035
Pearson          =   10.0267936                   (1/df) Pearson  =  1.671132
```

```
Variance function: V(u) = u*(1-u/n)              [Binomial]
Link function    : g(u) = ln(u/(n-u))            [Logit]

                                                 AIC             =  5.178781
Log likelihood   = -18.71512262                  BIC             = -1.244442
```

r	OIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
ldose	34.27034	2.912141	11.77	0.000	28.56265	39.97803
_cons	-60.71747	5.180713	-11.72	0.000	-70.87149	-50.56346

The only difference between `blogit` and `glm` here is how they obtain the answer. `blogit` expands the data to contain 481 observations (the sum of `n`) so that it can run Stata's standard, individual-level logistic command. `glm`, on the other hand, uses the information on the binomial denominator directly. We specified `family(binomial n)`, meaning that variable `n` contains the denominator. Parameter estimates and standard errors from the two approaches do not differ.

An alternative model, which gives asymmetric sigmoid curves for p, involves the complementary log-log, or cloglog, function:

$$\ln\{-\ln(1-p)\} = \beta_0 + \beta_1 X$$

We fit this model by using `glm`:

```
. glm r ldose, family(binomial n) link(cloglog)

Iteration 0:   log likelihood = -14.883594
Iteration 1:   log likelihood = -14.822264
Iteration 2:   log likelihood = -14.822228
Iteration 3:   log likelihood = -14.822228

Generalized linear models                        No. of obs      =         8
Optimization     : ML                            Residual df     =         6
                                                 Scale parameter =         1
Deviance         =  3.446418004                  (1/df) Deviance =   .574403
Pearson          =  3.294675153                  (1/df) Pearson  =  .5491125

Variance function: V(u) = u*(1-u/n)              [Binomial]
Link function    : g(u) = ln(-ln(1-u/n))         [Complementary log-log]

                                                 AIC             =  4.205557
Log likelihood   = -14.82222811                  BIC             = -9.030231
```

r	OIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
ldose	22.04118	1.793089	12.29	0.000	18.52679	25.55557
_cons	-39.57232	3.229047	-12.26	0.000	-45.90114	-33.24351

The complementary log-log model is preferred; the deviance for the logistic model, 11.23, is much higher than the deviance for the cloglog model, 3.45. This change also is evident by comparing log likelihoods, or equivalently, AIC values.

This example also shows the advantage of the `glm` command—we can vary assumptions easily. Note the minor difference in what we typed to obtain the logistic and cloglog models:

```
. glm r ldose, family(binomial n) link(logit)
. glm r ldose, family(binomial n) link(cloglog)
```

If we were performing this work for ourselves, we would have typed the commands in a more abbreviated form:

```
. glm r ldose, f(b n) l(l)
. glm r ldose, f(b n) l(cl)
```

◁

❑ Technical note

Factor variables may be used with `glm`. Say that, in the example above, we had `ldose`, the log dose of insecticide; `n`, the number of flour beetles subjected to each dose; and `r`, the number killed—all as before—except that now we have results for three different kinds of beetles. Our hypothetical data include `beetle`, which contains the values 1, 2, and 3.

```
. use http://www.stata-press.com/data/r12/beetle
. list, sep(0)
```

	beetle	ldose	n	r
1.	1	1.6907	59	6
2.	1	1.7242	60	13
3.	1	1.7552	62	18
4.	1	1.7842	56	28
5.	1	1.8113	63	52
	(*output omitted*)			
23.	3	1.861	64	23
24.	3	1.8839	58	22

Let's assume that, at first, we wish merely to add a shift factor for the type of beetle. We could type

```
. glm r i.beetle ldose, f(bin n) l(cloglog)
Iteration 0:   log likelihood = -79.012269
Iteration 1:   log likelihood =  -76.94951
Iteration 2:   log likelihood = -76.945645
Iteration 3:   log likelihood = -76.945645
Generalized linear models                         No. of obs      =         24
Optimization     : ML                             Residual df     =         20
                                                  Scale parameter =          1
Deviance         =  73.76505595                   (1/df) Deviance =   3.688253
Pearson          =   71.8901173                   (1/df) Pearson  =   3.594506
Variance function: V(u) = u*(1-u/n)               [Binomial]
Link function    : g(u) = ln(-ln(1-u/n))          [Complementary log-log]
                                                  AIC             =    6.74547
Log likelihood   = -76.94564525                   BIC             =   10.20398
```

r	OIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.0910396	.1076132	-0.85	0.398	-.3019576	.1198783

ldose	19.41558	.9954265	19.50	0.000	17.46458	21.36658
_cons	-34.84602	1.79333	-19.43	0.000	-38.36089	-31.33116

We find strong evidence that the insecticide works differently on the third kind of beetle. We now check whether the curve is merely shifted or also differently sloped:

```
. glm r beetle##c.ldose, f(bin n) l(cloglog)
Iteration 0:   log likelihood = -67.270188
Iteration 1:   log likelihood = -65.149316
Iteration 2:   log likelihood = -65.147978
Iteration 3:   log likelihood = -65.147978
Generalized linear models                         No. of obs      =         24
Optimization     : ML                             Residual df     =         18
                                                  Scale parameter =          1
Deviance         =  50.16972096                   (1/df) Deviance =  2.787207
Pearson          =  49.28422567                   (1/df) Pearson  =  2.738013
Variance function: V(u) = u*(1-u/n)               [Binomial]
Link function    : g(u) = ln(-ln(1-u/n))          [Complementary log-log]
                                                  AIC             =  5.928998
Log likelihood   = -65.14797776                   BIC             = -7.035248
```

r	OIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.79933	4.470882	-0.18	0.858	-9.562098	7.963438

beetle#c.ldose						
2	.3838708	2.478477	0.15	0.877	-4.473855	5.241596
3	-10.726	2.526412	-4.25	0.000	-15.67768	-5.774321
_cons	-39.57232	3.229047	-12.26	0.000	-45.90114	-33.24351

We find that the (complementary log-log) dose–response curve for the third kind of beetle has roughly half the slope of that for the first kind.

See [U] **25 Working with categorical data and factor variables**; what is said there concerning linear regression is applicable to any GLM model.

❑

Variance estimators

glm offers many variance options and gives different types of standard errors when used in various combinations. We highlight some of them here, but for a full explanation, see Hardin and Hilbe (2007).

▷ Example 3

Continuing with our flour beetle data, we rerun the most recently displayed model, this time requesting estimation via IRLS.

```
. use http://www.stata-press.com/data/r12/beetle
. glm r beetle##c.ldose, f(bin n) l(cloglog) ltol(1e-15) irls
Iteration 1:   deviance =  54.41414
Iteration 2:   deviance =  50.19424
Iteration 3:   deviance =  50.16973
  (output omitted)
Iteration 17:  deviance =  50.16972
Generalized linear models                         No. of obs      =        24
Optimization     : MQL Fisher scoring             Residual df     =        18
                   (IRLS EIM)                     Scale parameter =         1
Deviance         =  50.16972096                   (1/df) Deviance =  2.787207
Pearson          =  49.28422567                   (1/df) Pearson  =  2.738013
Variance function: V(u) = u*(1-u/n)               [Binomial]
Link function    : g(u) = ln(-ln(1-u/n))          [Complementary log-log]
                                                  BIC             = -7.035248
```

r	EIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.79933	4.586649	-0.17	0.862	-9.788997	8.190337
3	17.78741	4.624834	3.85	0.000	8.7229	26.85192
ldose	22.04118	1.799356	12.25	0.000	18.5145	25.56785
beetle#c.ldose						
2	.3838708	2.544068	0.15	0.880	-4.602411	5.370152
3	-10.726	2.548176	-4.21	0.000	-15.72033	-5.731665
_cons	-39.57232	3.240274	-12.21	0.000	-45.92314	-33.2215

Note our use of the ltol() option, which, although unrelated to our discussion on variance estimation, was used so that the regression coefficients would match those of the previous Newton–Raphson (NR) fit.

Because IRLS uses the EIM for optimization, the variance estimate is also based on EIM. If we want optimization via IRLS but the variance estimate based on OIM, we specify glm, irls vce(oim):

```
. glm r beetle##c.ldose, f(b n) l(cl) ltol(1e-15) irls vce(oim) noheader nolog
```

r	OIM Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.79933	4.470882	-0.18	0.858	-9.562098	7.963438
3	17.78741	4.586429	3.88	0.000	8.798172	26.77664
ldose	22.04118	1.793089	12.29	0.000	18.52679	25.55557
beetle#c.ldose						
2	.3838708	2.478477	0.15	0.877	-4.473855	5.241596
3	-10.726	2.526412	-4.25	0.000	-15.67768	-5.774321
_cons	-39.57232	3.229047	-12.26	0.000	-45.90114	-33.24351

This approach is identical to NR except for the convergence path. Because the cloglog link is not the canonical link for the binomial family, EIM and OIM produce different results. Both estimators, however, are asymptotically equivalent.

Going back to NR, we can also specify `vce(robust)` to get the Huber/White/sandwich estimator of variance:

```
. glm r beetle##c.ldose, f(b n) l(cl) vce(robust) noheader nolog
```

r	Robust Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.79933	5.733049	-0.14	0.889	-12.0359	10.43724
3	17.78741	5.158477	3.45	0.001	7.676977	27.89784
ldose	22.04118	.8998551	24.49	0.000	20.27749	23.80486
beetle#c.ldose						
2	.3838708	3.174427	0.12	0.904	-5.837892	6.605633
3	-10.726	2.800606	-3.83	0.000	-16.21508	-5.236912
_cons	-39.57232	1.621306	-24.41	0.000	-42.75003	-36.39462

The sandwich estimator gets its name from the form of the calculation—it is the multiplication of three matrices, with the outer two matrices (the "bread") set to the OIM variance matrix. When `irls` is used along with `vce(robust)`, the EIM variance matrix is instead used as the bread. Using a result from McCullagh and Nelder (1989), Newson (1999) points out that the EIM and OIM variance matrices are equivalent under the canonical link. Thus if `irls` is specified with the canonical link, the resulting variance is labeled "Robust". When the noncanonical link for the family is used, which is the case in the example below, the EIM and OIM variance matrices differ, so the resulting variance is labeled "Semirobust".

```
. glm r beetle##c.ldose, f(b n) l(cl) irls ltol(1e-15) vce(robust) noheader
> nolog
```

r	Coef.	Semirobust Std. Err.	z	P>|z|	[95% Conf.	Interval]
beetle						
2	-.79933	6.288963	-0.13	0.899	-13.12547	11.52681
3	17.78741	5.255307	3.38	0.001	7.487194	28.08762

_cons	-39.57232	1.632544	-24.24	0.000	-42.77205	-36.3726

The outer product of the gradient (OPG) estimate of variance is one that avoids the calculation of second derivatives. It is equivalent to the "middle" part of the sandwich estimate of variance and can be specified by using `glm, vce(opg)`, regardless of whether NR or IRLS optimization is used.

```
. glm r beetle##c.ldose, f(b n) l(cl) vce(opg) noheader nolog
```

r	Coef.	OPG Std. Err.	z	P>|z|	[95% Conf.	Interval]

3	-10.726	3.796448	-2.83	0.005	-18.1669	-3.285097
_cons	-39.57232	6.433101	-6.15	0.000	-52.18097	-26.96368

The OPG estimate of variance is a component of the BHHH (Berndt et al. 1974) optimization technique. This method of optimization is also available with `glm` with the `technique()` option; however, the `technique()` option is not allowed with the `irls` option.

◁

▷ Example 4

The Newey–West (1987) estimator of variance is a sandwich estimator with the "middle" of the sandwich modified to take into account possible autocorrelation between the observations. These estimators are a generalization of those given by the Stata command `newey` for linear regression. See [TS] **newey** for more details.

For example, consider the dataset given in [TS] **newey**, which has time-series measurements on `usr` and `idle`. We want to perform a linear regression with Newey–West standard errors.

```
. use http://www.stata-press.com/data/r12/idle2
. list usr idle time
```

	usr	idle	time
1.	0	100	1
2.	0	100	2
3.	0	97	3
4.	1	98	4
5.	2	94	5
	(*output omitted*)		
29.	1	98	29
30.	1	98	30

Examining *Methods and formulas* of [TS] **newey**, we see that the variance estimate is multiplied by a correction factor of $n/(n-k)$, where k is the number of regressors. `glm, vce(hac ...)` does not make this correction, so to get the same standard errors, we must use the `vfactor()` option within `glm` to make the correction manually.

```
. display 30/28
1.0714286
. tsset time
        time variable:  time, 1 to 30
                delta:  1 unit
. glm usr idle, vce(hac nwest 3) vfactor(1.0714286)
Iteration 0:   log likelihood = -71.743396
Generalized linear models                         No. of obs      =         30
Optimization     : ML                             Residual df     =         28
                                                  Scale parameter =   7.493297
Deviance         =  209.8123165                   (1/df) Deviance =   7.493297
Pearson          =  209.8123165                   (1/df) Pearson  =   7.493297
Variance function: V(u) = 1                       [Gaussian]
Link function    : g(u) = u                       [Identity]
HAC kernel (lags): Newey-West (3)
                                                  AIC             =   4.916226
Log likelihood   = -71.74339627                   BIC             =   114.5788
```

usr	Coef.	HAC Std. Err.	z	P>|z|	[95% Conf.	Interval]
idle	-.2281501	.0690928	-3.30	0.001	-.3635694	-.0927307
_cons	23.13483	6.327033	3.66	0.000	10.73407	35.53558

The `glm` command above reproduces the results given in [TS] **newey**. We may now generalize this output to models other than simple linear regression and to different kernel weights.

```
. glm usr idle, fam(gamma) link(log) vce(hac gallant 3)
Iteration 0:   log likelihood =  -61.76593
Iteration 1:   log likelihood = -60.963233

```

`glm` also offers variance estimators based on the bootstrap (resampling your data with replacement) and the jackknife (refitting the model with each observation left out in succession). Also included is the one-step jackknife estimate, which, instead of performing full reestimation when each observation is omitted, calculates a one-step NR estimate, with the full data regression coefficients as starting values.

```
. set seed 1
. glm usr idle, fam(gamma) link(log) vce(bootstrap, reps(100) nodots)

```

See Hardin and Hilbe (2007) for a full discussion of the variance options that go with `glm` and, in particular, of how the different variance estimators are modified when `vce(cluster` *clustvar*`)` is specified. Finally, not all variance options are supported with all types of weights. See `help glm` for a current table of the variance options that are supported with the different weights.

User-defined functions

glm may be called with a user-written link function, variance (family) function, Newey–West kernel-weight function, or any combination of the three.

Syntax of link functions

```
program progname
        version 12
        args todo eta mu return
        if 'todo' == -1 {
                /* Set global macros for output */
                global SGLM_lt "title for link function"
                global SGLM_lf "subtitle showing link definition"
                exit
        }
        if 'todo' == 0 {
                /* set η=g(μ) */
                /* Intermediate calculations go here */
                generate double 'eta' = ...
                exit
        }
        if 'todo' == 1 {
                /* set μ=g^-1(η) */
                /* Intermediate calculations go here */
                generate double 'mu' = ...
                exit
        }
        if 'todo' == 2 {
                /* set return = ∂μ/∂η */
                /* Intermediate calculations go here */
                generate double 'return' = ...
                exit
        }
        if 'todo' == 3 {
                /* set return = ∂^2μ/∂η^2 */
                /* Intermediate calculations go here */
                generate double 'return' = ...
                exit
        }
        display as error "Unknown call to glm link function"
        exit 198
end
```

Syntax of variance functions

```
program progname
        version 12
        args todo eta mu return
        if `todo' == -1 {
                /*  Set global macros for output  */
                /*  Also check that depvar is in proper range */
                /*  Note: For this call,  eta contains indicator for whether each obs. is in est. sample  */
                global SGLM_vt "title for variance function"
                global SGLM_vf "subtitle showing function definition"
                global SGLM_mu "program to call to enforce boundary conditions on μ"
                exit
        }
        if `todo' == 0 {
                /*  set η to initial value.  */
                /*  Intermediate calculations go here  */
                generate double `eta' = ...
                exit
        }
        if `todo' == 1 {
                /*  set return = V(μ)  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        if `todo' == 2 {
                /*  set return = ∂V(μ)/∂μ  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        if `todo' == 3 {
                /*  set return =  squared deviance (per observation)  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        if `todo' == 4 {
                /*  set return =  Anscombe residual  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        if `todo' == 5 {
                /*  set return =  log likelihood  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        if `todo' == 6 {
                /*  set return =  adjustment for deviance residuals  */
                /*  Intermediate calculations go here  */
                generate double `return' = ...
                exit
        }
        display as error "Unknown call to glm variance function"
        exit 198
end
```

Syntax of Newey–West kernel-weight functions

```
program progname, rclass
        version 12
        args G j
        /* G  is the maximum lag */
        /* j  is the current lag */
        /*  Intermediate calculations go here */
        return scalar wt = computed weight
        return local setype "Newey-West"
        return local sewtype "name of kernel"
end
```

Global macros available for user-written programs

Global macro	Description
SGLM_V	program name of variance (family) evaluator
SGLM_L	program name of link evaluator
SGLM_y	dependent variable name
SGLM_m	binomial denominator
SGLM_a	negative binomial k
SGLM_p	power if power() or opower() is used, or an argument from a user-specified link function
SGLM_s1	indicator; set to one if scale is equal to one
SGLM_ph	value of scale parameter

▷ Example 5

Suppose that we wish to perform Poisson regression with a log-link function. Although this regression is already possible with standard glm, we will write our own version for illustrative purposes.

Because we want a log link, $\eta = g(\mu) = \ln(\mu)$, and for a Poisson family the variance function is $V(\mu) = \mu$.

The Poisson density is given by

$$f(y_i) = \frac{e^{-\exp(\mu_i)} e^{\mu_i y_i}}{y_i!}$$

resulting in a log likelihood of

$$L = \sum_{i=1}^{n} \{-e^{\mu_i} + \mu_i y_i - \ln(y_i!)\}$$

The squared deviance of the ith observation for the Poisson family is given by

$$d_i^2 = \begin{cases} 2\widehat{\mu}_i & \text{if } y_i = 0 \\ 2\{y_i \ln(y_i/\widehat{\mu}_i) - (y_i - \widehat{\mu}_i)\} & \text{otherwise} \end{cases}$$

We now have enough information to write our own Poisson-log `glm` module. We create the file `mylog.ado`, which contains

```
program mylog
        version 12
        args todo eta mu return
        if `todo' == -1 {
                global SGLM_lt "My Log"          // Titles for output
                global SGLM_lf "ln(u)"
                exit
        }
        if `todo' == 0  {
                gen double `eta' = ln(`mu')      // η = ln(μ)
                exit
        }
        if `todo' == 1  {
                gen double `mu' = exp(`eta')     // μ = exp(η)
                exit
        }
        if `todo' == 2 {
                gen double `return' = `mu'       // ∂μ/∂η = exp(η) = μ
                exit
        }
        if `todo' == 3 {
                gen double `return' = `mu'       // ∂²μ/∂η² = exp(η) = μ
                exit
        }
        di as error "Unknown call to glm link function"
        exit 198
end
```

and we create the file `mypois.ado`, which contains

```
program mypois
        version 12
        args todo eta mu return
        if `todo' == -1 {
                local y     "$SGLM_y"
                local touse "`eta'"                 // `eta' marks estimation sample here
                capture assert `y'>=0 if `touse'    // check range of y
                if _rc {
                        di as error `"dependent variable `y' has negative values"'
                        exit 499
                }
                global SGLM_vt "My Poisson"         // Titles for output
                global SGLM_vf "u"
                global SGLM_mu "glim_mu 0 ."        // see note 1
                exit
        }
        if `todo' == 0 {                            // Initialization of η; see note 2
                gen double `eta' = ln(`mu')
                exit
        }
```

```
        if `todo' == 1 {
                gen double `return' =  `mu'          //  V(μ) = μ
                exit
        }
        if `todo' == 2 {                             //  ∂V(μ)/∂μ
                gen byte `return' = 1
                exit
        }
        if `todo' == 3 {                             //  squared deviance, defined above
                local y "$SGLM_y"
                if "`y'" == "" {
                        local y "`e(depvar)'"
                }
                gen double `return' = cond(`y'==0, 2*`mu', /*
                          */ 2*(`y'*ln(`y'/`mu')-(`y'-`mu')))
                exit
        }
        if `todo' == 4 {                             //  Anscombe residual; see note 3
                local y "$SGLM_y"
                if "`y'" == "" {
                        local y "`e(depvar)'"
                }
                gen double `return' = 1.5*(`y'^(2/3)-`mu'^(2/3)) / `mu'^(1/6)
                exit
        }
        if `todo' == 5 {                             //  log likelihood; see note 4

                exit
        }
        di as error "Unknown call to glm variance function"
        error 198
end
```

Notes:

1. `glim_mu` is a Stata program that will, at each iteration, bring $\widehat{\mu}$ back into its plausible range, should it stray out of it. Here `glim_mu` is called with the arguments zero and missing, meaning that zero is the lower bound of $\widehat{\mu}$ and there exists no upper bound—such is the case for Poisson models.

2. Here the initial value of η is easy because we intend to fit this model with our user-defined log link. In general, however, the initialization may need to vary according to the link to obtain convergence. If so, the global macro `SGLM_L` is used to determine which link is being utilized.

3. The Anscombe formula is given here because we know it. If we were not interested in Anscombe residuals, we could merely set `` `return' `` to missing. Also, the local macro `y` is set either to `SGLM_y` if it is in current estimation or to `e(depvar)` if this function is being accessed by `predict`.

4. If we were not interested in ML estimation, we could omit this code entirely and just leave an `exit` statement in its place. Similarly, if we were not interested in deviance or IRLS optimization, we could set `` `return' `` in the deviance portion of the code (`` `todo'==3 ``) to missing.

5. This code defines the term to be added to the predicted residuals if the `adjusted` option is specified. Again, if we were not interested, we could set `'return'` to missing.

We can now test our Poisson-log module by running it on the airline data presented in [R] **poisson**.

```

(Standard errors scaled using dispersion equal to square root of 1.)
```

These are precisely the results given in [R] **poisson** and are those that would have been given had we run `glm, family(poisson) link(log)`. The only minor adjustment we needed to make was to specify the `scale(1)` option. If `scale()` is left unspecified, `glm` assumes `scale(1)` for discrete distributions and `scale(x2)` for continuous ones. By default, `glm` assumes that any user-defined family is continuous because it has no way of checking. Thus we needed to specify `scale(1)` because our model is discrete.

Because we were careful in defining the squared deviance, we could have fit this model with IRLS. Because log is the canonical link for the Poisson family, we would not only get the same regression coefficients but also the same standard errors.

◁

▷ Example 6

Suppose now that we wish to use our log link (`mylog.ado`) with `glm`'s binomial family. This task requires some modification because our current function is not equipped to deal with the binomial denominator, which we are allowed to specify. This denominator is accessible to our link function through the global macro `SGLM_m`. We now make the modifications and store them in `mylog2.ado`.

```
program mylog2                                                  // <-- changed
        version 12
        args todo eta mu return
        if `todo' == -1 {
                global SGLM_lt "My Log, Version 2"              // <-- changed
                if "$SGLM_m" == "1" {                           // <-- changed
                        global SGLM_lf "ln(u)"                  // <-- changed
                }                                               // <-- changed
                else    global SGLM_lf "ln(u/$SGLM_m)"          // <-- changed
                exit
        }
        if `todo' == 0  {
                gen double `eta' = ln(`mu'/$SGLM_m)             // <-- changed
                exit
        }
        if `todo' == 1  {
                gen double `mu' = $SGLM_m*exp(`eta')            // <-- changed
                exit
        }
        if `todo' == 2 {
                gen double `return' = `mu'
                exit
        }
        if `todo' == 3 {
                gen double `return' = `mu'
                exit
        }
        di as error "Unknown call to glm link function"
        exit 198
end
```

We can now run our new log link with `glm`'s binomial family. Using the flour beetle data from earlier, we have

```
. use http://www.stata-press.com/data/r12/beetle, clear

◁

For a more detailed discussion on user-defined functions, and for an example of a user-defined Newey–West kernel weight, see Hardin and Hilbe (2007).

John Ashworth Nelder (1924–2010) was born in Somerset, England. He studied mathematics and statistics at Cambridge and worked as a statistician at the National Vegetable Research Station and then Rothamsted Experimental Station. In retirement, he was actively affiliated with Imperial College London. Nelder was especially well known for his contributions to the theory of linear models and to statistical computing. He was the principal architect of generalized and hierarchical generalized linear models and of the programs GenStat and GLIM.

Robert William Maclagan Wedderburn (1947–1975) was born in Edinburgh and studied mathematics and statistics at Cambridge. At Rothamsted Experimental Station, he developed the theory of generalized linear models with Nelder and originated the concept of quasilikelihood. He died of anaphylactic shock from an insect bite on a canal holiday.

Saved results

glm, ml saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(df)	residual degrees of freedom
e(phi)	scale parameter
e(aic)	model AIC
e(bic)	model BIC
e(ll)	log likelihood, if NR
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance
e(deviance)	deviance
e(deviance_s)	scaled deviance
e(deviance_p)	Pearson deviance
e(deviance_ps)	scaled Pearson deviance
e(dispers)	dispersion
e(dispers_s)	scaled dispersion
e(dispers_p)	Pearson dispersion
e(dispers_ps)	scaled Pearson dispersion
e(nbml)	1 if negative binomial parameter estimated via ML, 0 otherwise
e(vf)	factor set by vfactor(), 1 if not set
e(power)	power set by power(), opower()
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	glm
e(cmdline)	command as typed

e(varfunct)	variance title
e(varfuncf)	variance function
e(link)	program to calculate link function
e(linkt)	link title
e(linkf)	link function
e(m)	number of binomial trials
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald; type of model χ^2 test
e(cons)	set if noconstant specified
e(hac_kernel)	HAC kernel
e(hac_lag)	HAC lag
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	ml or irls
e(opt1)	optimization title, line 1
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

`glm, irls` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(k)`	number of parameters
`e(k_eq_model)`	number of equations in overall model test
`e(df_m)`	model degrees of freedom
`e(df)`	residual degrees of freedom
`e(phi)`	scale parameter
`e(disp)`	dispersion parameter
`e(bic)`	model BIC
`e(N_clust)`	number of clusters
`e(deviance)`	deviance
`e(deviance_s)`	scaled deviance
`e(deviance_p)`	Pearson deviance
`e(deviance_ps)`	scaled Pearson deviance
`e(dispers)`	dispersion
`e(dispers_s)`	scaled dispersion
`e(dispers_p)`	Pearson dispersion
`e(dispers_ps)`	scaled Pearson dispersion
`e(nbml)`	`1` if negative binomial parameter estimated via ML, `0` otherwise
`e(vf)`	factor set by `vfactor()`, 1 if not set
`e(power)`	power set by `power()`, `opower()`
`e(rank)`	rank of `e(V)`
`e(rc)`	return code

Macros

`e(cmd)`	`glm`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(varfunc)`	program to calculate variance function
`e(varfunct)`	variance title
`e(varfuncf)`	variance function
`e(link)`	program to calculate link function
`e(linkt)`	link title

`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(clustvar)`	name of cluster variable
`e(offset)`	linear offset variable
`e(cons)`	set if `noconstant` specified
`e(hac_kernel)`	HAC kernel
`e(hac_lag)`	HAC lag
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(opt)`	`ml` or `irls`
`e(opt1)`	optimization title, line 1
`e(opt2)`	optimization title, line 2
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`
`e(marginsok)`	predictions allowed by `margins`
`e(marginsnotok)`	predictions disallowed by `margins`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

`e(b)`	coefficient vector
`e(Cns)`	constraints matrix
`e(V)`	variance–covariance matrix of the estimators
`e(V_modelbased)`	model-based variance

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`glm` is implemented as an ado-file.

The canonical reference on GLM is McCullagh and Nelder (1989). The term "generalized linear model" is from Nelder and Wedderburn (1972). Many people use the acronym GLIM for GLM models because of the classic GLM software tool GLIM, by Baker and Nelder (1985). See Dobson and Barnett (2008) for a concise introduction and overview. See Rabe-Hesketh and Everitt (2007) for more examples of GLM using Stata. Hoffmann (2004) focuses on applying generalized linear models, using real-world datasets, along with interpreting computer output, which for the most part is obtained using Stata.

This discussion highlights the details of parameter estimation and predicted statistics. For a more detailed treatment, and for information on variance estimation, see Hardin and Hilbe (2007). `glm` supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

`glm` obtains results by IRLS, as described in McCullagh and Nelder (1989), or by maximum likelihood using Newton–Raphson. The implementation here, however, allows user-specified weights, which we denote as v_j for the jth observation. Let M be the number of "observations" ignoring weights. Define

$$w_j = \begin{cases} 1 & \text{if no weights are specified} \\ v_j & \text{if } \texttt{fweights} \text{ or } \texttt{iweights} \text{ are specified} \\ Mv_j/(\sum_k v_k) & \text{if } \texttt{aweights} \text{ or } \texttt{pweights} \text{ are specified} \end{cases}$$

The number of observations is then $N = \sum_j w_j$ if `fweights` are specified and $N = M$ otherwise. Each IRLS step is performed by `regress` using w_j as the weights.

Let d_j^2 denote the squared deviance residual for the jth observation:

For the Gaussian family, $d_j^2 = (y_j - \widehat{\mu}_j)^2$.

For the Bernoulli family (binomial with denominator 1),

$$d_j^2 = \begin{cases} -2\ln(1-\widehat{\mu}_j) & \text{if } y_j = 0 \\ -2\ln(\widehat{\mu}_j) & \text{otherwise} \end{cases}$$

For the binomial family with denominator m_j,

$$d_j^2 = \begin{cases} 2y_j\ln(y_j/\widehat{\mu}_j) + 2(m_j - y_j)\ln\{(m_j - y_j)/(m_j - \widehat{\mu}_j)\} & \text{if } 0 < y_j < m_j \\ 2m_j\ln\{m_j/(m_j - \widehat{\mu}_j)\} & \text{if } y_j = 0 \\ 2y_j\ln(y_j/\widehat{\mu}_j) & \text{if } y_j = m_j \end{cases}$$

For the Poisson family,

$$d_j^2 = \begin{cases} 2\widehat{\mu}_j & \text{if } y_j = 0 \\ 2\{y_j\ln(y_j/\widehat{\mu}_j) - (y_j - \widehat{\mu}_j)\} & \text{otherwise} \end{cases}$$

For the gamma family, $d_j^2 = -2\{\ln(y_j/\widehat{\mu}_j) - (y_j - \widehat{\mu}_j)/\widehat{\mu}_j\}$.

For the inverse Gaussian, $d_j^2 = (y_j - \widehat{\mu}_j)^2/(\widehat{\mu}_j^2 y_j)$.

For the negative binomial,

$$d_j^2 = \begin{cases} 2\ln(1+k\widehat{\mu}_j)/k & \text{if } y_j = 0 \\ 2y_j\ln(y_j/\widehat{\mu}_j) - 2\{(1+ky_j)/k\}\ln\{(1+ky_j)/(1+k\widehat{\mu}_j)\} & \text{otherwise} \end{cases}$$

Let $\phi = 1$ if the scale parameter is set to one; otherwise, define $\phi = \widehat{\phi}_0(n-k)/n$, where $\widehat{\phi}_0$ is the estimated scale parameter and k is the number of covariates in the model (including intercept).

Let $\ln L_j$ denote the log likelihood for the jth observation:

For the Gaussian family,

$$\ln L_j = -\frac{1}{2}\left[\left\{\frac{(y_j-\widehat{\mu}_j)^2}{\phi}\right\} + \ln(2\pi\phi)\right]$$

For the binomial family with denominator m_j (Bernoulli if all $m_j = 1$),

$$\ln L_j = \phi \times \begin{cases} \ln\{\Gamma(m_j+1)\} - \ln\{\Gamma(y_j+1)\} + \ln\{\Gamma(m_j-y_j+1)\} \\ \quad +(m_j-y_j)\ln(1-\widehat{\mu}_j/m_j) + y_j\ln(\widehat{\mu}_j/m_j) & \text{if } 0 < y_j < m_j \\ m_j\ln(1-\widehat{\mu}_j/m_j) & \text{if } y_j = 0 \\ m_j\ln(\widehat{\mu}_j/m_j) & \text{if } y_j = m_j \end{cases}$$

For the Poisson family,

$$\ln L_j = \phi\,[y_j\ln(\widehat{\mu}_j) - \widehat{\mu}_j - \ln\{\Gamma(y_j+1)\}]$$

For the gamma family, $\ln L_j = -y_j/\widehat{\mu}_j + \ln(1/\widehat{\mu}_j)$.

For the inverse Gaussian,

$$\ln L_j = -\frac{1}{2}\left\{\frac{(y_j-\widehat{\mu}_j)^2}{y_j\widehat{\mu}_j^2} + 3\ln(y_j) + \ln(2\pi)\right\}$$

For the negative binomial (let $m = 1/k$),

$$\begin{aligned}\ln L_j = &\phi\,[\ln\{\Gamma(m+y_j)\} - \ln\{\Gamma(y_j+1)\} - \ln\{\Gamma(m)\} \\ &-m\ln(1+\widehat{\mu}_j/m) + y_j\ln\{\widehat{\mu}_j/(\widehat{\mu}_j+m)\}]\end{aligned}$$

The overall deviance reported by `glm` is $D^2 = \sum_j w_j d_j^2$. The dispersion of the deviance is D^2 divided by the residual degrees of freedom.

The Akaike information criterion (AIC) and Bayesian information criterion (BIC) are given by

$$\begin{aligned}\text{AIC} &= \frac{-2\ln L + 2k}{N} \\ \text{BIC} &= D^2 - (N-k)\ln(N)\end{aligned}$$

where $\ln L = \sum_j w_j \ln L_j$ is the overall log likelihood.

The Pearson deviance reported by `glm` is $\sum_j w_j r_j^2$. The corresponding Pearson dispersion is the Pearson deviance divided by the residual degrees of freedom. `glm` also calculates the scaled versions of all these quantities by dividing by the estimated scale parameter.

Acknowledgments

`glm` was written by James Hardin, University of South Carolina, and Joseph Hilbe, Arizona State University. The previous version of this routine was written by Patrick Royston, MRC Clinical Trials Unit, London. The original version of this routine was published in Royston (1994). Royston's work, in turn, was based on a prior implementation by Joseph Hilbe, first published in Hilbe (1993). Roger Newson wrote an early implementation (Newson 1999) of robust variance estimates for GLM. Parts of this entry are excerpts from Hardin and Hilbe (2007).

Title

glm postestimation — Postestimation tools for glm

Description

The following postestimation commands are available after `glm`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

statistic	Description
Main	
mu	expected value of y; the default
xb	linear prediction $\eta = \mathbf{x}\widehat{\boldsymbol{\beta}}$
eta	synonym of xb
stdp	standard error of the linear prediction
anscombe	Anscombe (1953) residuals
cooksd	Cook's distance
deviance	deviance residuals
hat	diagonals of the "hat" matrix
likelihood	a weighted average of standardized deviance and standardized Pearson residuals
pearson	Pearson residuals
response	differences between the observed and fitted outcomes
score	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$
working	working residuals

options	Description
Options	
nooffset	modify calculations to ignore offset variable
adjusted	adjust deviance residual to speed up convergence
standardized	multiply residual by the factor $(1-h)^{-1/2}$
studentized	multiply residual by one over the square root of the estimated scale parameter
modified	modify denominator of residual to be a reasonable estimate of the variance of *depvar*

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`mu`, `xb`, `stdp`, and `score` are the only statistics allowed with `svy` estimation results.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`mu`, the default, specifies that `predict` calculate the expected value of y, equal to $g^{-1}(\mathbf{x}\widehat{\boldsymbol{\beta}})$ [$ng^{-1}(\mathbf{x}\widehat{\boldsymbol{\beta}})$ for the binomial family].

`xb` calculates the linear prediction $\eta = \mathbf{x}\widehat{\boldsymbol{\beta}}$.

`eta` is a synonym for `xb`.

`stdp` calculates the standard error of the linear prediction.

`anscombe` calculates the Anscombe (1953) residuals to produce residuals that closely follow a normal distribution.

`cooksd` calculates Cook's distance, which measures the aggregate change in the estimated coefficients when each observation is left out of the estimation.

`deviance` calculates the deviance residuals. Deviance residuals are recommended by McCullagh and Nelder (1989) and by others as having the best properties for examining the goodness of fit of a GLM. They are approximately normally distributed if the model is correct. They may be plotted against the fitted values or against a covariate to inspect the model's fit. Also see the `pearson` option below.

`hat` calculates the diagonals of the "hat" matrix as an analog to simple linear regression.

`likelihood` calculates a weighted average of standardized deviance and standardized Pearson residuals.

`pearson` calculates the Pearson residuals. Pearson residuals often have markedly skewed distributions for nonnormal family distributions. Also see the `deviance` option above.

`response` calculates the differences between the observed and fitted outcomes.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

`working` calculates the working residuals, which are response residuals weighted according to the derivative of the link function.

Options

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `glm`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`adjusted` adjusts the deviance residual to speed up the convergence to the limiting normal distribution. The adjustment deals with adding to the deviance residual a higher-order term that depends on the variance function family. This option is allowed only when `deviance` is specified.

`standardized` requests that the residual be multiplied by the factor $(1-h)^{-1/2}$, where h is the diagonal of the hat matrix. This operation is done to account for the correlation between *depvar* and its predicted value.

`studentized` requests that the residual be multiplied by one over the square root of the estimated scale parameter.

`modified` requests that the denominator of the residual be modified to be a reasonable estimate of the variance of *depvar*. The base residual is multiplied by the factor $(k/w)^{-1/2}$, where k is either one or the user-specified dispersion parameter and w is the specified weight (or one if left unspecified).

Remarks

Remarks are presented under the following headings:

Predictions
Other postestimation commands

Predictions

▷ Example 1

After `glm` estimation, `predict` may be used to obtain various predictions based on the model. In example 2 of [R] **glm**, we mentioned that the complementary log-log link seemed to fit the data better than the logit link. Now we go back and obtain the fitted values and deviance residuals:

```
. use http://www.stata-press.com/data/r12/ldose
. glm r ldose, f(binomial n) l(logit)
  (output omitted)
. predict mu_logit
(option mu assumed; predicted mean r)
. predict dr_logit, deviance
. quietly glm r ldose, f(binomial n) l(cloglog)
. predict mu_cl
(option mu assumed; predicted mean r)
. predict dr_cl, d
. format mu_logit dr_logit mu_cl dr_cl %9.5f
. list r mu_logit dr_logit mu_cl dr_cl, sep(4)
```

	r	mu_logit	dr_logit	mu_cl	dr_cl
1.	6	3.45746	1.28368	5.58945	0.18057
2.	13	9.84167	1.05969	11.28067	0.55773
3.	18	22.45139	-1.19611	20.95422	-0.80330
4.	28	33.89761	-1.59412	30.36942	-0.63439
5.	52	50.09584	0.60614	47.77644	1.28883
6.	53	53.29092	-0.12716	54.14273	-0.52366
7.	61	59.22216	1.25107	61.11331	-0.11878
8.	60	58.74297	1.59398	59.94723	0.32495

In six of the eight cases, $|$`dr_logit`$| > |$`dr_cl`$|$. The above represents only one of the many available options for `predict`. See Hardin and Hilbe (2007) for a more in-depth examination.

◁

Other postestimation commands

❑ Technical note

After `glm` estimation, you may perform any of the postestimation commands that you would perform after any other kind of estimation in Stata; see [U] **20 Estimation and postestimation commands**. Below we test the joint significance of all the interaction terms.

```
. use http://www.stata-press.com/data/r12/beetle, clear
. glm r beetle##c.ldose, f(bin n) l(cloglog)
  (output omitted)
. testparm i.beetle beetle#c.ldose
 ( 1)  [r]2.beetle = 0
 ( 2)  [r]3.beetle = 0
 ( 3)  [r]2.beetle#c.ldose = 0
 ( 4)  [r]3.beetle#c.ldose = 0
           chi2(  4) =  249.69
         Prob > chi2 =    0.0000
```

If you wanted to print the variance–covariance matrix of the estimators, you would type `estat vce`.

If you use the `linktest` postestimation command, you must also specify the `family()` and `link()` options; see [R] **linktest**.

❑

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

We follow the terminology used in *Methods and formulas* of [R] **glm**.

The deviance residual calculated by `predict` following `glm` is $d_j = \text{sign}(y_j - \widehat{\mu}_j)\sqrt{d_j^2}$.

The Pearson residual calculated by `predict` following `glm` is

$$r_j = \frac{y_j - \widehat{\mu}_j}{\sqrt{V(\widehat{\mu}_j)}}$$

where $V(\widehat{\mu}_j)$ is the family-specific variance function.

$$V(\widehat{\mu}_j) = \begin{cases} \widehat{\mu}_j(1 - \widehat{\mu}_j/m_j) & \text{if binomial or Bernoulli } (m_j = 1) \\ \widehat{\mu}_j^2 & \text{if gamma} \\ 1 & \text{if Gaussian} \\ \widehat{\mu}_j^3 & \text{if inverse Gaussian} \\ \widehat{\mu}_j + k\widehat{\mu}_j^2 & \text{if negative binomial} \\ \widehat{\mu}_j & \text{if Poisson} \end{cases}$$

The response residuals are given by $r_i^R = y_i - \mu_i$. The working residuals are

$$r_i^W = (y_i - \widehat{\mu}_i)\left(\frac{\partial \eta}{\partial \mu}\right)_i$$

and the score residuals are

$$r_i^S = \frac{y_i - \widehat{\mu}_i}{V(\widehat{\mu}_i)}\left(\frac{\partial \eta}{\partial \mu}\right)_i^{-1}$$

Define $\widehat{W} = V(\widehat{\mu})$ and X to be the covariate matrix. h_i, then, is the ith diagonal of the hat matrix given by

$$\widehat{H} = \widehat{W}^{1/2}X(X^T\widehat{W}X)^{-1}X^T\widehat{W}^{1/2}$$

As a result, the likelihood residuals are given by

$$r_i^L = \text{sign}(y_i - \widehat{\mu}_i)\left\{h_i(r_i^{'})^2 + (1 - h_i)(d_i^{'})^2\right\}^{1/2}$$

where $r_i^{'}$ and $d_i^{'}$ are the standardized Pearson and standardized deviance residuals, respectively. By *standardized*, we mean that the residual is divided by $\{1 - h_i\}^{1/2}$.

Cook's distance is an overall measure of the change in the regression coefficients caused by omitting the ith observation from the analysis. Computationally, Cook's distance is obtained as

$$C_i = \frac{(r_i')^2 h_i}{k(1 - h_i)}$$

where k is the number of regressors, including the constant.

Anscombe residuals are given by

$$r_i^A = \frac{A(y_i) - A(\widehat{\mu}_i)}{A'(\widehat{\mu}_i)\{V(\widehat{\mu}_i)\}^{1/2}}$$

where

$$A(\cdot) = \int \frac{d\mu}{V^{1/3}(\mu)}$$

Deviance residuals may be adjusted (`predict, adjusted`) to make the following correction:

$$d_i^a = d_i + \frac{1}{6}\rho_3(\theta)$$

where $\rho_3(\theta)$ is a family-specific correction. See Hardin and Hilbe (2007) for the exact forms of $\rho_3(\theta)$ for each family.

Title

glogit — Logit and probit regression for grouped data

Syntax

Logistic regression for grouped data

`blogit` *pos_var pop_var* [*indepvars*] [*if*] [*in*] [, *blogit_options*]

Probit regression for grouped data

`bprobit` *pos_var pop_var* [*indepvars*] [*if*] [*in*] [, *bprobit_options*]

Weighted least-squares logistic regression for grouped data

`glogit` *pos_var pop_var* [*indepvars*] [*if*] [*in*] [, *glogit_options*]

Weighted least-squares probit regression for grouped data

`gprobit` *pos_var pop_var* [*indepvars*] [*if*] [*in*] [, *gprobit_options*]

blogit_options	Description
Model	
`noconstant`	suppress constant term
`asis`	retain perfect predictor variables
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`or`	report odds ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`nocoef`	do not display coefficient table; seldom used
`coeflegend`	display legend instead of statistics

bprobit_options	Description
Model	
noconstant	suppress constant term
asis	retain perfect predictor variables
offset(*varname*)	include *varname* in model with coefficient constrained to 1
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
nocoef	do not display coefficient table; seldom used
coeflegend	display legend instead of statistics

glogit_options	Description
SE	
vce(*vcetype*)	*vcetype* may be ols, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
or	report odds ratios
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
coeflegend	display legend instead of statistics

gprobit_options	Description
SE	
vce(*vcetype*)	*vcetype* may be ols, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

`bootstrap`, `by`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.

`nocoef` and `coeflegend` do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

blogit

Statistics > Binary outcomes > Grouped data > Logit regression for grouped data

bprobit

Statistics > Binary outcomes > Grouped data > Probit regression for grouped data

glogit

Statistics > Binary outcomes > Grouped data > Weighted least-squares logit regression

gprobit

Statistics > Binary outcomes > Grouped data > Weighted least-squares probit regression

Description

`blogit` and `bprobit` produce maximum-likelihood logit and probit estimates on grouped ("blocked") data; `glogit` and `gprobit` produce weighted least-squares estimates. In the syntax diagrams above, *pos_var* and *pop_var* refer to variables containing the total number of positive responses and the total population.

See [R] **logistic** for a list of related estimation commands.

Options for blogit and bprobit

Model

`noconstant`; see [R] **estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

`offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

or (blogit only) reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

The following options are available with blogit and bprobit but are not shown in the dialog box:

nocoef specifies that the coefficient table not be displayed. This option is sometimes used by program writers but is useless interactively.

coeflegend; see [R] **estimation options**.

Options for glogit and gprobit

SE

vce(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory and that use bootstrap or jackknife methods; see [R] ***vce_option***.

vce(ols), the default, uses the standard variance estimator for ordinary least-squares regression.

Reporting

level(#); see [R] **estimation options**.

or (glogit only) reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

The following option is available with glogit and gprobit but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Maximum likelihood estimates
Weighted least-squares estimates

Maximum likelihood estimates

`blogit` produces the same results as `logit` and `logistic`, and `bprobit` produces the same results as `probit`, but the "blocked" commands accept data in a slightly different "shape". Consider the following two datasets:

```
. use http://www.stata-press.com/data/r12/xmpl1
. list, sepby(agecat)
```

	agecat	exposed	died	pop
1.	0	0	0	115
2.	0	0	1	5
3.	0	1	0	98
4.	0	1	1	8
5.	1	0	0	69
6.	1	0	1	16
7.	1	1	0	76
8.	1	1	1	22

```
. use http://www.stata-press.com/data/r12/xmpl2
. list
```

	agecat	exposed	deaths	pop
1.	0	0	5	120
2.	0	1	8	106
3.	1	0	16	85
4.	1	1	22	98

These two datasets contain the same information; observations 1 and 2 of `xmpl1` correspond to observation 1 of `xmpl2`, observations 3 and 4 of `xmpl1` correspond to observation 2 of `xmpl2`, and so on.

The first observation of `xmpl1` says that for `agecat==0` and `exposed==0`, 115 subjects did not die (`died==0`). The second observation says that for the same `agecat` and `exposed` groups, five subjects did die (`died==1`). In `xmpl2`, the first observation says that there were five deaths of a population of 120 in `agecat==0` and `exposed==0`. These are two different ways of saying the same thing. Both datasets are transcriptions from the following table, reprinted in Rothman, Greenland, and Lash (2008, 260), for age-specific deaths from all causes for tolbutamide and placebo treatment groups (University Group Diabetes Program 1970):

	Age through 54		Age 55 and above	
	Tolbutamide	Placebo	Tolbutamide	Placebo
Dead	8	5	22	16
Surviving	98	115	76	79

The data in `xmpl1` are said to be "fully relational", which is computer jargon meaning that each observation corresponds to one cell of the table. Stata typically prefers data in this format. The second form of storing these data in `xmpl2` is said to be "folded", which is computer jargon for something less than fully relational.

`blogit` and `bprobit` deal with "folded" data and produce the same results that `logit` and `probit` would have if the data had been stored in the "fully relational" representation.

Example 1

For the tolbutamide data, the fully relational representation is preferred. We could then use `logistic`, `logit`, and any of the epidemiological table commands; see [R] **logistic**, [R] **logit**, and [ST] **epitab**. Nevertheless, there are occasions when the folded representation seems more natural. With `blogit` and `bprobit`, we avoid the tedium of having to unfold the data:

```
. use http://www.stata-press.com/data/r12/xmpl2
. blogit deaths pop agecat exposed, or
Logistic regression for grouped data              Number of obs   =        409
                                                  LR chi2(2)      =      22.47
                                                  Prob > chi2     =     0.0000
Log likelihood =  -142.6212                       Pseudo R2       =     0.0730

------------------------------------------------------------------------------
    _outcome | Odds Ratio   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      agecat |   4.216299   1.431519     4.24   0.000     2.167361    8.202223
     exposed |   1.404674   .4374454     1.09   0.275     .7629451    2.586175
       _cons |   .0513818   .0170762    -8.93   0.000     .0267868    .0985593
------------------------------------------------------------------------------
```

If we had not specified the `or` option, results would have been presented as coefficients instead of as odds ratios. The estimated odds ratio of death for tolbutamide exposure is 1.40, although the 95% confidence interval includes 1. (By comparison, these data, in fully relational form and analyzed using the `cs` command [see [ST] **epitab**], produce a Mantel–Haenszel weighted odds ratio of 1.40 with a 95% confidence interval of 0.76 to 2.59.)

We can see the underlying coefficients by replaying the estimation results and not specifying the `or` option:

```
. blogit
Logistic regression for grouped data              Number of obs   =        409
                                                  LR chi2(2)      =      22.47
                                                  Prob > chi2     =     0.0000
Log likelihood =  -142.6212                       Pseudo R2       =     0.0730

------------------------------------------------------------------------------
    _outcome |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      agecat |   1.438958   .3395203     4.24   0.000     .7735101    2.104405
     exposed |   .3398053   .3114213     1.09   0.275    -.2705692    .9501798
       _cons |  -2.968471     .33234    -8.93   0.000    -3.619846   -2.317097
------------------------------------------------------------------------------
```

▷ Example 2

`bprobit` works like `blogit`, substituting the probit for the logit-likelihood function.

```
. bprobit deaths pop agecat exposed
Probit regression for grouped data                Number of obs   =        409
                                                  LR chi2(2)      =      22.58
                                                  Prob > chi2     =     0.0000
Log likelihood = -142.56478                       Pseudo R2       =     0.0734

------------------------------------------------------------------------------
    _outcome |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      agecat |   .7542049   .1709692     4.41   0.000     .4191114    1.089298
     exposed |   .1906236   .1666059     1.14   0.253    -.1359179    .5171651
       _cons |  -1.673973   .1619594   -10.34   0.000    -1.991408   -1.356539
------------------------------------------------------------------------------
```

◁

Weighted least-squares estimates

▷ Example 3

We have state data for the United States on the number of marriages (`marriage`), the total population aged 18 years or more (`pop18p`), and the median age (`medage`). The dataset excludes Nevada, so it has 49 observations. We now wish to estimate a logit equation for the marriage rate. We will include age squared by specifying the term `c.medage#c.medage`:

```
. use http://www.stata-press.com/data/r12/census7
(1980 Census data by state)
. glogit marriage pop18p medage c.medage#c.medage
Weighted LS logistic regression for grouped data

      Source |       SS       df       MS              Number of obs =      49
-------------+------------------------------           F(  2,    46) =   12.89
       Model |  .71598314      2   .35799157           Prob > F      =  0.0000
    Residual |  1.27772858    46  .027776708           R-squared     =  0.3591
-------------+------------------------------           Adj R-squared =  0.3313
       Total |  1.99371172    48  .041535661           Root MSE      =  .16666

------------------------------------------------------------------------------
             |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`blogit`, `bprobit`, `glogit`, and `gprobit` are implemented as ado-files.

Methods and formulas are presented under the following headings:

Maximum likelihood estimates
Weighted least-squares estimates

Maximum likelihood estimates

The results reported by `blogit` and `bprobit` are obtained by maximizing a weighted logit- or probit-likelihood function. Let $F(\,)$ denote the normal- or logistic-likelihood function. The likelihood of observing each observation in the data is then

$$F(\beta x)^s\{1-F(\beta x)\}^{t-s}$$

where s is the number of successes and t is the population. The term above is counted as contributing $s+(t-s)=t$ degrees of freedom. All of this follows directly from the definitions of logit and probit.

`blogit` and `bprobit` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

Weighted least-squares estimates

The logit function is defined as the log of the odds ratio. If there is one explanatory variable, the model can be written as

$$\log\left(\frac{p_j}{1-p_j}\right)=\beta_0+\beta_1 x_j+\epsilon_j \tag{1}$$

where p_j represents successes divided by population for the jth observation. (If there is more than one explanatory variable, we simply interpret β_1 as a row vector and x_j as a column vector.) The large-sample expectation of ϵ_j is zero, and its variance is

$$\sigma_j^2=\frac{1}{n_j p_j(1-p_j)}$$

where n_j represents the population for observation j. We can thus apply weighted least squares to the observations, with weights proportional to $n_j p_j(1-p_j)$.

As in any feasible generalized least-squares problem, estimation proceeds in two steps. First, we fit (1) by OLS and compute the predicted probabilities as

$$\widehat{p_j}=\frac{\exp(\widehat{\beta_0}+\widehat{\beta_1}x_j)}{1+\exp(\widehat{\beta_0}+\widehat{\beta_1}x_j)}$$

In the second step, we fit (1) by using analytic weights equal to $n_j\widehat{p_j}(1-\widehat{p_j})$.

For `gprobit`, write $\Phi(\cdot)$ for the cumulative normal distribution, and define z_j implicitly by $\Phi(z_j) = p_j$, where p_j is the fraction of successes for observation j. The probit model for one explanatory variable can be written as

$$\Phi^{-1}(p_j) = \beta_0 + \beta_1 x_j + \epsilon_j$$

(If there is more than one explanatory variable, we simply interpret β_1 as a row vector and x_j as a column vector.)

The expectation of ϵ_j is zero, and its variance is given by

$$\sigma_j^2 = \frac{p_j(1-p_j)}{n_j \phi^2\{\Phi^{-1}(p_j)\}}$$

where $\phi(\cdot)$ represents the normal density (Amemiya 1981, 1498). We can thus apply weighted least squares to the observations with weights proportional to $1/\sigma_j^2$. As for grouped logit, we use a two-step estimator to obtain the weighted least-squares estimates.

Title

glogit postestimation — Postestimation tools for glogit, gprobit, blogit, and bprobit

Description

The following postestimation commands are available after `glogit`, `gprobit`, `blogit`, and `bprobit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
* `estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* `lrtest`	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

* `estat ic` and `lrtest` are not appropriate after `glogit` and `gprobit`.

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [, *statistic*]

statistic	Description
Main	
`n`	predicted count; the default
`pr`	probability of a positive outcome
`xb`	linear prediction
`stdp`	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`n`, the default, calculates the expected count, that is, the estimated probability times *pop_var*, which is the total population.

`pr` calculates the predicted probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

gmm — Generalized method of moments estimation

Syntax

Interactive version

`gmm` (*eqname*$_1$`:`]<*mexp*$_1$>) (*eqname*$_2$`:`]<*mexp*$_2$>)...[*if*] [*in*] [*weight*] [`,` *options*]

Moment-evaluator program version

`gmm` *moment_prog* [*if*] [*in*] [*weight*] `,` { `equations(`*namelist*`)` | `nequations(#)` }
{ `parameters(`*namelist*`)` | `nparameters(#)` } [*options*] [*program_options*]

where

mexp$_j$ is the substitutable expression for the jth moment equation and

moment_prog is a moment-evaluator program.

options	Description
Model	
`derivative(`<*dexp*$_{mn}$>`)`	specify derivative of *mexp*$_m$ with respect to parameter n; can be specified more than once (interactive version only)
* `twostep`	use two-step GMM estimator; the default
* `onestep`	use one-step GMM estimator
* `igmm`	use iterative GMM estimator
Instruments	
`instruments(`[<*eqlist*>`:`]*varlist*[`, noconstant`]`)`	specify instruments; can be specified more than once
`xtinstruments(`[<*eqlist*>`:`]*varlist*`, lags(`#$_1$`/`#$_2$`))`	specify panel-style instruments; can be specified more than once
Weight matrix	
`wmatrix(`*wmtype*[`, independent`]`)`	specify weight matrix; *wmtype* may be `robust`, `cluster` *clustvar*, `hac` *kernel* [*lags*], or `unadjusted`
`center`	center moments in weight-matrix computation
`winitial(`*iwtype*[`, independent`]`)`	specify initial weight matrix; *iwtype* may be `identity`, `unadjusted`, `xt` *xtspec*, or the name of a Stata matrix

Options

variables(*varlist*)	specify variables in model
nocommonesample	do not restrict estimation sample to be the same for all equations

SE/Robust

vce(*vcetype*[, independent])	*vcetype* may be robust, cluster *clustvar*, bootstrap, jackknife, hac *kernel lags*, or unadjusted

Reporting

level(#)	set confidence level; default is level(95)
title(*string*)	display *string* as title above the table of parameter estimates
title2(*string*)	display *string* as subtitle
display_options	control column formats and line width

Optimization

from(*initial_values*)	specify initial values for parameters
‡ igmmiterate(#)	specify maximum number of iterations for iterated GMM estimator
‡ igmmeps(#)	specify # for iterated GMM parameter convergence criterion; default is igmmeps(1e-6)
‡ igmmweps(#)	specify # for iterated GMM weight-matrix convergence criterion; default is igmmweps(1e-6)
optimization_options	control the optimization process; seldom used
coeflegend	display legend instead of statistics

* You can specify at most one of these options.

‡ These options may be specified only when igmm is specified.

program_options	Description

Model

evaluator_options	additional options to be passed to the moment-evaluator program
hasderivatives	moment-evaluator program can calculate derivatives
* equations(*namelist*)	specify moment-equation names
* nequations(#)	specify number of moment equations
‡ parameters(*namelist*)	specify parameter names
‡ nparameters(#)	specify number of parameters

* You must specify equations(*namelist*) or nequations(#); you may specify both.

‡ You must specify parameters(*namelist*) or nparameters(#); you may specify both.

bootstrap, by, jackknife, rolling, statsby, and xi are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
aweights are not allowed with the jackknife prefix; see [R] **jackknife**.
aweights, fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

<*mexp*$_j$> and <*dexp*$_{mn}$> are extensions of valid Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must otherwise satisfy the naming requirements for variables; `{beta}` is an example of a parameter. Also allowed is a notation of the form {<*eqname*>:*varlist*} for linear combinations of multiple covariates and their parameters. For example, `{xb: mpg price turn}` defines a linear combination of the variables `mpg`, `price`, and `turn`. See *Substitutable expressions* under *Remarks* below.

Menu

Statistics > Endogenous covariates > Generalized method of moments estimation

Description

`gmm` performs generalized method of moments (GMM) estimation. With the interactive version of the command, you enter the moment equations directly into the dialog box or on the command line using substitutable expressions. The moment-evaluator program version gives you greater flexibility in exchange for increased complexity; with this version, you write a program in an ado-file that calculates the moments based on a vector of parameters passed to it.

`gmm` can fit both single- and multiple-equation models, and it allows moment conditions of the form $E\{\mathbf{z}_i u_i(\beta)\} = \mathbf{0}$, where $\mathbf{z}_i$ is a vector of instruments and $u_i(\beta)$ is often an additive regression error term, as well as more general moment conditions of the form $E\{\mathbf{h}_i(\mathbf{z}_i;\beta)\} = \mathbf{0}$. `gmm` works with cross-sectional, time-series, and longitudinal (panel) data.

Options

Model

`derivative(`[*eqname* | #]`/`*name* `=` <*dexp*$_{mn}$>`)` specifies the derivative of moment equation *eqname* or # with respect to parameter *name*. If *eqname* or # is not specified, `gmm` assumes that the derivative applies to the first moment equation.

For a moment equation of the form $E\{\mathbf{z}_{mi}u_{mi}(\beta)\} = \mathbf{0}$, `derivative(`*m*`/`$\beta_j$ `=` <*dexp*$_{mn}$>`)` is to contain a substitutable expression for $\partial u_{mi}/\partial\beta_j$.

For a moment equation of the form $E\{h_{mi}(\mathbf{z}_i;\beta)\} = \mathbf{0}$, `derivative(`*m*`/`$\beta_j$ `=` <*dexp*$_{mn}$>`)` is to contain a substitutable expression for $\partial h_{mi}/\partial\beta_j$.

<*dexp*$_{mn}$> uses the same substitutable expression syntax as is used to specify moment equations. If you declare a linear combination in a moment equation, you provide the derivative for the linear combination; `gmm` then applies the chain rule for you. See *Specifying derivatives* under *Remarks* below for examples.

If you do not specify the `derivative()` option, `gmm` calculates derivatives numerically. You must either specify no derivatives or specify all the derivatives that are not identically zero; you cannot specify some analytic derivatives and have `gmm` compute the rest numerically.

`twostep`, `onestep`, and `igmm` specify which estimator is to be used. You can specify at most one of these options. `twostep` is the default.

`twostep` requests the two-step GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, and then reestimates the parameters based on that weight matrix.

`onestep` requests the one-step GMM estimator. The parameters are estimated based on an initial weight matrix, and no updating of the weight matrix is performed except when calculating the appropriate variance–covariance (VCE) matrix.

`igmm` requests the iterative GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, reestimates the parameters based on that weight matrix, computes a new weight matrix, and so on, to convergence. Convergence is declared when the relative change in the parameter vector is less than `igmmeps()`, the relative change in the weight matrix is less than `igmmweps()`, or `igmmiterate()` iterations have been completed. Hall (2005, sec. 2.4 and 3.6) mentions that there may be gains to finite-sample efficiency from using the iterative estimator.

Instruments

`instruments(`[*<eqlist>*`:`]*varlist*[`, noconstant`]`)` specifies a list of instrumental variables to be used. If you specify a single moment equation, then you do not need to specify the equations to which the instruments apply; you can omit the *eqlist* and simply specify `instruments(`*varlist*`)`. By default, a constant term is included in *varlist*; to omit the constant term, use the `noconstant` suboption: `instruments(`*varlist*`, noconstant)`.

If you specify a model with multiple moment conditions of the form

$$E\left\{\begin{array}{c}\mathbf{z}_{1i}u_{1i}(\beta)\\ \cdots\\ \mathbf{z}_{qi}u_{qi}(\beta)\end{array}\right\}=\mathbf{0}$$

then you can specify the equations to indicate the moment equations for which the list of variables is to be used as instruments if you do not want that list applied to all the moment equations. For example, you might type

```
gmm (main:<mexp1>) (<mexp2>) (<mexp3>), instruments(z1 z2) ///
  instruments(2: z3) instruments(main 3: z4)
```

Variables `z1` and `z2` will be used as instruments for all three equations, `z3` will be used as an instrument for the second equation, and `z4` will be used as an instrument for the first and third equations. Notice that we chose to supply a name for the first moment equation but not the second two.

`xtinstruments(`[*<eqlist>*`:`]*varlist*`, lags(`*#*$_1$`/`*#*$_2$`))` is for use with panel-data models in which the set of available instruments depends on the time period. As with `instruments()`, you can prefix the list of variables with equation names or numbers to target instruments to specific equations. Unlike with `instruments()`, a constant term is not included in *varlist*. You must `xtset` your data before using this option; see [XT] **xtset**.

If you specify

```
gmm ..., xtinstruments(x, lags(1/.)) ...
```

then for panel i and period t, `gmm` uses as instruments $x_{i,t-1}, x_{i,t-2}, \ldots, x_{i1}$. More generally, specifying `xtinstruments(x, lags(`*#*$_1$`, `*#*$_2$`))` uses as instruments $x_{i,t-\#_1}, \ldots, x_{i,t-\#_2}$; setting $\#_2$ `= .` requests all available lags. *#*$_1$ and *#*$_2$ must be zero or positive integers.

`gmm` automatically excludes observations for which no valid instruments are available. It does, however, include observations for which only a subset of the lags is available. For example, if you request that lags one through three be used, then `gmm` will include the observations for the second and third time periods even though fewer than three lags are available as instruments.

Weight matrix

`wmatrix(`*wmtype*[`, independent`]`)` specifies the type of weight matrix to be used in conjunction with the two-step and iterated GMM estimators.

Specifying `wmatrix(robust)` requests a weight matrix that is appropriate when the errors are independent but not necessarily identically distributed. `wmatrix(robust)` is the default.

Specifying `wmatrix(cluster` *clustvar*`)` requests a weight matrix that accounts for arbitrary correlation among observations within clusters identified by *clustvar*.

Specifying `wmatrix(hac` *kernel #*`)` requests a heteroskedasticity- and autocorrelation-consistent (HAC) weight matrix using the specified kernel (see below) with # lags. The bandwidth of a kernel is equal to the number of lags plus one.

Specifying `wmatrix(hac` *kernel* `opt)` requests an HAC weight matrix using the specified kernel, and the lag order is selected using Newey and West's (1994) optimal lag-selection algorithm.

Specifying `wmatrix(hac` *kernel*`)` requests an HAC weight matrix using the specified kernel and $N - 2$ lags, where N is the sample size.

There are three kernels available for HAC weight matrices, and you may request each one by using the name used by statisticians or the name perhaps more familiar to economists:

`bartlett` or `nwest` requests the Bartlett (Newey–West) kernel;

`parzen` or `gallant` requests the Parzen (Gallant) kernel; and

`quadraticspectral` or `andrews` requests the quadratic spectral (Andrews) kernel.

Specifying `wmatrix(unadjusted)` requests a weight matrix that is suitable when the errors are homoskedastic. In some applications, the GMM estimator so constructed is known as the (nonlinear) two-stage least-squares (2SLS) estimator.

Including the `independent` suboption creates a weight matrix that assumes moment equations are independent. This suboption is often used to replicate other models that can be motivated outside the GMM framework, such as the estimation of a system of equations by system-wide 2SLS. This suboption has no effect if only one moment equation is specified.

`wmatrix()` has no effect if `onestep` is also specified.

`center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`winitial(`*wmtype*[`, independent`]`)` specifies the weight matrix to use to obtain the first-step parameter estimates.

Specifying `winitial(unadjusted)` requests a weighting matrix that assumes the moment equations are independent and identically distributed. This matrix is of the form $(\mathbf{Z}'\mathbf{Z})^{-1}$, where $\mathbf{Z}$ represents all the instruments specified in the `instruments()` option. To avoid a singular weight matrix, you should specify at least $q - 1$ moment equations of the form $E\{\mathbf{z}_{hi}u_{hi}(\beta)\} = \mathbf{0}$, where q is the number of moment equations, or you should specify the `independent` suboption.

Including the `independent` suboption creates a weight matrix that assumes moment equations are independent. Elements of the weight matrix corresponding to covariances between two moment equations are set equal to zero. This suboption has no effect if only one moment equation is specified.

`winitial(unadjusted)` is the default.

`winitial(xt` *xtspec*`)` is for use with dynamic panel-data models in which one of the moment equations is specified in first-differences form. *xtspec* is a string consisting of the letters "L" and "D", the length of which is equal to the number of moment equations in the model. You specify

"L" for a moment equation if that moment equation is written in levels, and you specify "D" for a moment equation if it is written in first-differences; *xtspec* is not case sensitive. When you specify this option, you can specify at most one moment equation in levels and one moment equation in first-differences. See the examples listed in *Dynamic panel-data models* under *Remarks* below.

`winitial(identity)` requests that the identity matrix be used.

`winitial(`*matname*`)` requests that Stata matrix *matname* be used. You cannot specify the `independent` suboption if you specify `winitial(`*matname*`)`.

Options

`variables(`*varlist*`)` specifies the variables in the model. `gmm` ignores observations for which any of these variables has a missing value. If you do not specify `variables()`, then `gmm` assumes all the observations are valid and issues an error message with return code 480 if any moment equations evaluate to missing for any observations at the initial value of the parameter vector.

`nocommonesample` requests that `gmm` not restrict the estimation sample to be the same for all equations. By default, `gmm` will restrict the estimation sample to observations that are available for all equations in the model, mirroring the behavior of other multiple-equation estimators such as `nlsur`, `sureg`, or `reg3`. For certain models, however, different equations can have different numbers of observations. For these models, you should specify `nocommonesample`. See *Dynamic panel-data models* below for one application of this option. You cannot specify weights if you specify `nocommonesample`.

SE/Robust

`vce(`*vcetype*`[ , independent ])` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(unadjusted)` specifies that an unadjusted (nonrobust) VCE matrix be used; this, along with the `twostep` option, results in the "optimal two-step GMM" estimates often discussed in textbooks.

The default *vcetype* is based on the *wmtype* specified in the `wmatrix()` option. If `wmatrix()` is specified but `vce()` is not, then *vcetype* is set equal to *wmtype*. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`.

Specifying `vce(bootstrap)` or `vce(jackknife)` results in standard errors based on the bootstrap or jackknife, respectively. See [R] ***vce_option***, [R] **bootstrap**, and [R] **jackknife** for more information on these VCEs.

The syntax for *vcetype*s other than `bootstrap` and `jackknife` are identical to those for `wmatrix()`.

Reporting

`level(#)`; see [R] **estimation options**.

`title(`*string*`)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(`*string*`)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Optimization

`from(`*initial_values*`)` specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where k is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
gmm ..., from(alpha 1.23 delta 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `gmm` exits with error code 480. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `gmm` ignores the row and column names of the matrix.

`igmmiterate(#)`, `igmmeps(#)`, and `igmmweps(#)` control the iterative process for the iterative GMM estimator. These options can be specified only if you also specify `igmm`.

`igmmiterate(#)` specifies the maximum number of iterations to perform with the iterative GMM estimator. The default is the number set using `set maxiter` (set [R] **maximize**), which is 16,000 by default.

`igmmeps(#)` specifies the convergence criterion used for successive parameter estimates when the iterative GMM estimator is used. The default is `igmmeps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

`igmmweps(#)` specifies the convergence criterion used for successive estimates of the weight matrix when the iterative GMM estimator is used. The default is `igmmweps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

optimization_options: `technique()`, `conv_maxiter()`, `conv_ptol()`, `conv_vtol()`, `conv_nrtol()`, `tracelevel()`. `technique()` specifies the optimization technique to use; `gn` (the default), `nr`, `dfp`, and `bfgs` are allowed. `conv_maxiter()` specifies the maximum number of iterations; `conv_ptol()`, `conv_vtol()`, and `conv_nrtol()` specify the convergence criteria for the parameters, gradient, and scaled Hessian, respectively. `tracelevel()` allows you to obtain additional details during the iterative process. See [M-5] **optimize( )**.

The following options pertain only to the moment-evaluator program version of `gmm`.

Model

evaluator_options refer to any options allowed by your *moment_prog*.

`hasderivatives` indicates that you have written your moment-evaluator program to compute derivatives. If you do not specify this option, derivatives are computed numerically. If your moment-evaluator program does compute derivatives but you wish to use numerical derivatives instead (perhaps during debugging), do not specify this option.

`equations(`*namelist*`)` specifies the names of the moment equations in the model. If you specify both `equations()` and `nequations()`, the number of names in the former must match the number specified in the latter.

`nequations(#)` specifies the number of moment equations in the model. If you do not specify names with the `equations()` option, `gmm` numbers the moment equations 1, 2, 3, ... If you specify both `equations()` and `nequations()`, the number of names in the former must match the number specified in the latter.

`parameters(`*namelist*`)` specifies the names of the parameters in the model. The names of the parameters must adhere to the naming conventions of Stata's variables; see [U] **11.3 Naming conventions**. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`nparameters(#)` specifies the number of parameters in the model. If you do not specify names with the `parameters()` option, `gmm` names them `b1`, `b2`, ..., `b#`. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

The following option is available with `gmm` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Introduction

The generalized method of moments (GMM) estimator is a workhorse of modern econometrics and is discussed in all the leading textbooks, including Cameron and Trivedi (2005, 2010), Davidson and MacKinnon (1993, 2004), Greene (2012, 468–506), Ruud (2000), Hayashi (2000), Wooldridge (2010), Hamilton (1994), and Baum (2006). An excellent treatise on GMM with a focus on time-series applications is Hall (2005). The collection of papers by Mátyás (1999) provides both theoretical and applied aspects of GMM. Here we give a brief introduction to the methodology and emphasize how the various options of `gmm` are used.

The starting point for the generalized method of moments (GMM) estimator is the analogy principle, which says we can estimate a parameter by replacing a population moment condition with its sample analogue. For example, the mean of an independent and identically distributed (i.i.d.) population is defined as the value μ such that the first (central) population moment is zero; that is, μ solves $E(y-\mu)=0$ where y is a random draw from the population. The analogy principle tells us that to obtain an estimate, $\widehat{\mu}$, of μ, we replace the population-expectations operator with its sample analogue (Manski 1988; Wooldridge 2010):

$$E(y-\mu)=0 \;\longrightarrow\; \frac{1}{N}\sum_{i=1}^{N}(y_i-\widehat{\mu})=0 \;\longrightarrow\; \widehat{\mu}=\frac{1}{N}\sum_{i=1}^{N}y_i$$

where N denotes sample size and y_i represents the ith observation of y in our dataset. The estimator $\widehat{\mu}$ is known as the method of moments (MM) estimator, because we started with a population moment condition and then applied the analogy principle to obtain an estimator that depends on the observed data.

Ordinary least-squares (OLS) regression can also be viewed as an MM estimator. In the model

$$y = \mathbf{x}'\beta + u$$

we assume that u has mean zero conditional on $\mathbf{x}$: $E(u|\mathbf{x}) = 0$. This conditional expectation implies the unconditional expectation $E(\mathbf{x}u) = \mathbf{0}$ because, using the law of iterated expectations,

$$E(\mathbf{x}u) = E_{\mathbf{x}}\left\{E(\mathbf{x}u|\mathbf{x})\right\} = E_{\mathbf{x}}\left\{\mathbf{x}\,E(u|\mathbf{x})\right\} = \mathbf{0}$$

(Using the law of iterated expectations to derive unconditional expectations based on conditional expectations, perhaps motivated by subject theory, is extremely common in GMM estimation.) Continuing,

$$E(\mathbf{x}u) = E\left\{\mathbf{x}(y - \mathbf{x}'\beta)\right\} = \mathbf{0}$$

Applying the analogy principle,

$$E\left\{\mathbf{x}(y - \mathbf{x}'\beta)\right\} \longrightarrow \frac{1}{N}\sum_{i=1}^{N}\mathbf{x}_i(y_i - \mathbf{x}_i'\beta) = \mathbf{0}$$

so that

$$\widehat{\beta} = \left(\sum\nolimits_i \mathbf{x}_i\mathbf{x}_i'\right)^{-1}\sum\nolimits_i \mathbf{x}_i y_i$$

which is just the more familiar formula $\widehat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$ written using summation notation.

In both the previous examples, the number of parameters we were estimating equaled the number of moment conditions. In the first example, we estimated one parameter, μ, and had one moment condition $E(y - \mu) = 0$. In the second example, the parameter vector β had k elements, as did the vector of regressors $\mathbf{x}$, yielding k moment conditions. Ignoring peculiar cases, a model of m equations in m unknowns has a unique solution, and because the moment equations in these examples were linear, we were able to solve for the parameters analytically. Had the moment conditions been nonlinear, we would have had to use numerical techniques to solve for the parameters, but that is not a significant limitation with modern computers.

What if we have more moment conditions than parameters? Say we have l moment conditions and k parameters. A model of $l > k$ equations in k unknowns does not have a unique solution. Any size-k subset of the moment conditions would yield a consistent parameter estimate, though the parameter estimate so obtained would in general be different based on which k moment conditions we used.

For concreteness, let's return to our regression model,

$$y = \mathbf{x}'\beta + u$$

but we no longer wish to assume that $E(\mathbf{x}u) = \mathbf{0}$; we suspect that the error term u affects one or more elements of $\mathbf{x}$. As a result, we can no longer use the OLS estimator. Suppose we have a vector $\mathbf{z}$ with the properties that $E(\mathbf{z}u) = \mathbf{0}$, that the rank of $E(\mathbf{z}'\mathbf{z})$ equals l, and that the rank of $E(\mathbf{z}'\mathbf{x}) = k$. The first assumption simply states that $\mathbf{z}$ is not correlated with the error term. The second assumption rules out perfect collinearity among the elements of $\mathbf{z}$. The third assumption, known as the *rank condition* in econometrics, ensures that $\mathbf{z}$ is sufficiently correlated with $\mathbf{x}$ and that the estimator is feasible. If some elements of $\mathbf{x}$ are not correlated with u, then they should also appear in $\mathbf{z}$.

If $l < k$, then the rank of $E(\mathbf{z}'\mathbf{x}) < k$, violating the rank condition.

If $l = k$, then we can use the simpler MM estimator we already discussed; we would obtain what is sometimes called the simple instrumental-variables estimator $\widehat{\beta} = (\sum_i \mathbf{z}_i\mathbf{x}_i')^{-1} \sum_i \mathbf{z}_i y_i$. The rank condition ensures that $\sum_i \mathbf{z}_i\mathbf{x}_i'$ is invertible, at least in the population.

If $l > k$, the GMM estimator chooses the value, $\widehat{\beta}$, that minimizes a quadratic function of the moment conditions. We could define

$$\widehat{\beta} \equiv \arg\min_\beta \left\{ \frac{1}{N}\sum\nolimits_i \mathbf{z}_i u_i(\beta) \right\}' \left\{ \frac{1}{N}\sum\nolimits_i \mathbf{z}_i u_i(\beta) \right\} \tag{1}$$

where for our linear regression example $u_i(\beta) = y_i - \mathbf{x}_i'\beta$. This estimator tries to make the moment conditions as close to zero as possible. This simple estimator, however, applies equal weight to each of the moment conditions; and as we shall see later, we can obtain more efficient estimators by choosing to weight some moment conditions more highly than others.

Consider the quadratic function

$$Q(\beta) = \left\{ \frac{1}{N}\sum\nolimits_i \mathbf{z}_i u_i(\beta) \right\}' \mathbf{W} \left\{ \frac{1}{N}\sum\nolimits_i \mathbf{z}_i u_i(\beta) \right\}$$

where $\mathbf{W}$ is a symmetric positive-definite matrix known as a weight matrix. Then we define the GMM estimator as

$$\widehat{\beta} \equiv \arg\min_\beta \; Q(\beta) \tag{2}$$

Continuing with our regression model example, if we choose

$$\mathbf{W} = \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i\mathbf{z}_i' \right)^{-1} \tag{3}$$

then we obtain

$$\widehat{\beta} = \left\{ \left(\frac{1}{N}\sum\nolimits_i \mathbf{x}_i\mathbf{z}_i' \right) \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i\mathbf{z}_i' \right)^{-1} \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i\mathbf{x}_i' \right) \right\}^{-1} \times \left(\frac{1}{N}\sum\nolimits_i \mathbf{x}_i\mathbf{z}_i' \right) \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i\mathbf{z}_i' \right)^{-1} \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i y_i \right)$$

which is the well-known two-stage least-squares (2SLS) estimator. Our choice of weight matrix here was based on the assumption that u was homoskedastic. A feature of GMM estimation is that by selecting different weight matrices, we can obtain estimators that can tolerate heteroskedasticity, clustering, autocorrelation, and other features of u. See [R] **ivregress** for more information about the 2SLS and linear GMM estimators.

Returning to the case where the model is "just identified", meaning that $l = k$, if we apply the GMM estimator, we will obtain the same estimate, $\widehat{\boldsymbol{\beta}}$, regardless of our choice of $\mathbf{W}$. Because $l = k$, if a unique solution exists, it will set all the sample moment conditions to zero jointly, so $\mathbf{W}$ has no impact on the value of β that minimizes the objective function.

We will highlight other features of the GMM estimator and the `gmm` command as we proceed through examples. First, though, we discuss how to specify moment equations by using substitutable expressions.

Substitutable expressions

To use the interactive version of `gmm`, you define the moment equations by using substitutable expressions. In most applications, your moment conditions are of the form $E\{\mathbf{z}_i u_i(\boldsymbol{\beta})\}$, where $u_i(\boldsymbol{\beta})$ is a residual term that depends on the parameter vector $\boldsymbol{\beta}$ as well as variables in your dataset, though we suppress expressing the variables for notational simplicity; we refer to $u_i(\boldsymbol{\beta})$ as the moment equation to differentiate it from the moment conditions $E\{z_i' u_i(\boldsymbol{\beta})\} = \mathbf{0}$.

Substitutable expressions in `gmm` work much like those used in `nl` and `nlsur`, though with one important difference. For the latter two commands, you type the name of the dependent variable, an equal sign, and then the regression function. For example, in `nl`, if you want to fit the function $y = f(\mathbf{x};\boldsymbol{\beta}) + u$, you would type

```
nl (y = <expression for f(x; β)>), ...
```

On the other hand, `gmm` requires you to write a substitutable expression for u; in this example, $u = y - f(\mathbf{x};\boldsymbol{\beta})$, so you would type

```
gmm (y - <expression for f(x; β)>), ...
```

The advantage of writing the substitutable expression directly in terms of u is that you are not restricted to fitting models with additive error terms as you are with `nl` and `nlsur`.

You specify substitutable expressions just like any other mathematical expression involving scalars and variables, such as those you would use with Stata's `generate` command, except that the parameters to be estimated are bound in braces. See [U] **13.2 Operators** and [U] **13.3 Functions** for more information on expressions. Parameter names must follow the same conventions as variable names. See [U] **11.3 Naming conventions**.

For example, say that the tth observation on a sample moment is

$$u_t = 1 - \beta\left\{(1 + r_{t+1})(c_{t+1}/c_t)^{-\gamma}\right\}$$

where t denotes time period, β and γ are the parameters to be estimated, and r and c are variables in your dataset. Then you would type

```
gmm (1 - {beta}*((1 + F.r)*(F.c/c)^(-1*{gamma}))), ...
```

Because β and γ are parameters, we enclose them in braces. Also notice our use of the forward operator to refer to the values of r and c one period ahead; time-series operators are allowed in substitutable expressions as long as you have previously `tsset` (see [TS] **tsset**) your data. See [U] **13.9 Time-series operators** for more information on time-series operators.

To specify initial values for some parameters, you can include an equal sign and the initial value after a parameter:

```
gmm (1 - {beta}*((1 + F.r)*(F.c/c)^(-1*{gamma=1}))), ...
```

would initialize γ to be one. If you do not specify an initial value for a parameter, it is initialized to zero.

Frequently, even nonlinear functions contain linear combinations of variables. As an example, suppose you have this moment equation:

$$u = \{y - \exp(\beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3)\} / \exp(\beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3)$$

Instead of typing

```
gmm ((y - exp({beta1}*x1 + {beta2}*x2 + {beta3}*x3)) /     ///
      exp({beta1}*x1 + {beta2}*x2 + {beta3}*x3)) ...
```

you can type

```
gmm ((y - exp({xb:x1 x2 x3})) / exp({xb:})) .....
```

The notation {xb:x1 x2 x3} tells gmm that you want a linear combination of the variables x1, x2, and x3. We named this linear combination xb, so gmm will name the three parameters corresponding to the three variables xb_x1, xb_x2, and xb_x3. You can name the linear combination anything you wish (subject to Stata's naming conventions for variable names); gmm then names the parameter corresponding to variable x *lc*_x, where *lc* is the name of your linear combination. You cannot use the same name for both an individual parameter and a linear combination. You can, however, refer to one parameter in a linear combination after it has been declared as you would any other parameter by using the notation {*lc*_x}. Linear combinations do not include a constant term.

Once we have declared the variables in the linear combination xb, we can subsequently refer to the linear combination in our substitutable expression by using the notation xb:. The colon is not optional; it tells gmm that you are referring to a previously declared linear combination, not an individual parameter. This shorthand notation is also handy when specifying derivatives, as we will show later.

In general, there are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in braces: {b0}, {param}, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: {b0=1}, {param=3.571}, etc.
3. Linear combinations of variables can be included using the notation {*eqname*:*varlist*}: {xb: mpg price weight}, {score: w x z}, etc. Parameters of linear combinations are initialized to zero.

If you specify initial values by using the from() option, they override whatever initial values are given within the substitutable expression. Substitutable expressions are so named because, once values are assigned to the parameters, the resulting expressions can be handled by generate and replace.

▷ Example 1: OLS regression

In *Introduction*, we stated that OLS is an MM estimator. Say that we want to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{length} + u$$

where u is an i.i.d. error term. We type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. gmm (mpg - {b1}*weight - {b2}*length - {b0}), instruments(weight length)
Step 1
Iteration 0:   GMM criterion Q(b) =   475.4138
Iteration 1:   GMM criterion Q(b) =  2.696e-20
Iteration 2:   GMM criterion Q(b) =  3.329e-27
Step 2
Iteration 0:   GMM criterion Q(b) =  5.109e-28
Iteration 1:   GMM criterion Q(b) =  7.237e-32
```

```
GMM estimation

Number of parameters =   3
Number of moments    =   3
Initial weight matrix: Unadjusted                 Number of obs   =        74
GMM weight matrix:     Robust
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
/b1	-.0038515	.0019472	-1.98	0.048	-.0076678	-.0000351
/b2	-.0795935	.0677528	-1.17	0.240	-.2123866	.0531996
/b0	47.88487	7.50599	6.38	0.000	33.1734	62.59634

```
Instruments for equation 1: weight length _cons
```

Recall that the moment condition for OLS regression is $E(\mathbf{x}u) = \mathbf{0}$, where $\mathbf{x}$, the list of instruments, is the same as the list of regressors in the model. In our command, we defined the residual term, u, inside parentheses by using a substitutable expression; because linear combinations declared in substitutable expressions do not include a constant term, we included our own (`b0`). Inside the `instruments()` option, we listed our instruments; by default, `gmm` includes a constant term among the instrument list.

Because the number of moments equals the number of parameters we are estimating, the model is said to be "just identified" or "exactly identified." Therefore, the choice of weight matrix has no impact on the solution to (2), and the criterion function $Q(\boldsymbol{\beta})$ achieves its minimum value at zero.

The OLS estimator is a one-step GMM estimator, but we did not bother to specify the `onestep` option because the model is just identified. Doing a second step of GMM estimation affects neither the point estimates nor the standard errors, so to keep the syntax as simple as possible, we did not include the `onestep` option. The first step of estimation resulted in $Q(\beta) = 0$ as expected, and the second step of estimation did not change the minimized value of $Q(\beta)$. (3×10^{-27} and 7×10^{-32} are both zero for all practical purposes.)

When you do not specify either the `wmatrix()` or the `vce()` option, `gmm` reports heteroskedasticity-robust standard errors. The parameter estimates reported here match those that we would obtain from the command

```
. regress mpg weight length, vce(robust)
```

The standard errors reported by that `regress` command would be larger than those reported by `gmm` by a factor of $\text{sqrt}(74/71)$ because `regress` makes a small-sample adjustment to the estimated variance matrix while `gmm` does not. Likewise, had we specified the `vce(unadjusted)` option with our `gmm` command, then our standard errors would differ by a factor of $\text{sqrt}(74/71)$ from those reported by `regress` without the `vce(robust)` option.

Using the notation for linear combinations of parameters, we could have typed

```
. gmm (mpg - {xb: weight length} - {b0}), instruments(weight length)
```

and obtained identical results. Instead of having parameters `b1` and `b2`, with this syntax we would have parameters `xb_weight` and `xb_length`.

◁

▷ Example 2: Instrumental-variables regression

In *Introduction*, we mentioned that 2SLS can be viewed as a GMM estimator. In example 1 of [R] **ivregress**, we fit by 2SLS a model of rental rates (`rent`) as a function of the value of owner-occupied housing (`hsngval`) and the percentage of the population living in urban areas (`pcturban`):

$$\texttt{rent} = \beta_0 + \beta_1\texttt{hsngval} + \beta_2\texttt{pcturban} + u$$

by 2SLS. We argued that random shocks that affect rental rates likely also affect housing values, so we treated `hsngval` as an endogenous variable. As additional instruments, we used family income, `faminc`, and three regional dummies (`reg2`–`reg4`).

To replicate the results of `ivregress 2sls` by using `gmm`, we type

```
. use http://www.stata-press.com/data/r12/hsng2
(1980 Census housing data)
. gmm (rent - {xb:hsngval pcturban} - {b0}),
> instruments(pcturban faminc reg2-reg4) vce(unadjusted) onestep
Step 1
Iteration 0:   GMM criterion Q(b) =   56115.03

```

We specified `vce(unadjusted)` so that we would obtain an unadjusted VCE matrix and our standard errors would match those reported in [R] **ivregress**.

Pay attention to how we specified the `instruments()` option. In *Introduction*, we mentioned that the moment conditions for the 2SLS estimator are $E(\mathbf{z}u) = \mathbf{0}$, and we mentioned that if some elements of $\mathbf{x}$ (the regressors) are not endogenous, then they should also appear in $\mathbf{z}$. In this model, we assume the regressor `pcturban` is exogenous, so we included it in the list of instrumental variables. Commands like `ivregress`, `ivprobit`, and `ivtobit` accept standard *varlist*s, so they can deduce the exogenous regressors in the model. Because `gmm` accepts arbitrary functions in the form of substitutable expressions, it has no way of discerning the exogenous variables of the model on its own.

Also notice that we specified the `onestep` option. The 2SLS estimator is a one-step GMM estimator that is based on a weight matrix that assumes the error terms are i.i.d. Unlike the previous example, here we had more instruments than parameters, so the minimized value of $Q(\beta)$ is nonzero. We discuss the weight matrix and its relationship to two-step estimation next.

◁

The weight matrix and two-step estimation

Recall our definition of the GMM estimator given in (2). The estimator, $\widehat{\boldsymbol{\beta}}$, depends on the choice of the weight matrix, $\mathbf{W}$. Under relatively mild assumptions, our estimator, $\widehat{\boldsymbol{\beta}}$, is consistent regardless of the choice of $\mathbf{W}$, so how are we to decide what $\mathbf{W}$ to use? The most common solution is to use the two-step estimator, which we now describe.

A key result in Hansen's (1982) seminal paper is that if we denote by $\mathbf{S}$ the covariance matrix of the moment conditions, then the optimal (in a way we make precise later) GMM estimator is the one that uses a weight matrix equal to the inverse of the moment covariance matrix. That is, if we let $\mathbf{S} = \mathrm{Cov}(\mathbf{z}u)$, then we want to use $\mathbf{W} = \mathbf{S}^{-1}$. But how do we obtain $\mathbf{S}$ in the first place?

If we assume that the errors are i.i.d., then

$$\mathrm{Cov}(\mathbf{z}u) = E(u^2\mathbf{z}\mathbf{z}') = \sigma^2 E(\mathbf{z}\mathbf{z}')$$

where σ^2 is the variance of u. Because σ^2 is a positive scalar, we can ignore it when solving (2). Thus we compute

$$\widehat{\mathbf{W}}_1 = \left(\frac{1}{N}\sum\nolimits_i \mathbf{z}_i\mathbf{z}_i'\right)^{-1} \tag{4}$$

which does not depend on any unknown model parameters. (Notice that $\widehat{\mathbf{W}}_1$ is the same weight matrix used in 2SLS.) Given $\widehat{\mathbf{W}}_1$, we can solve (2) to obtain an initial estimate, say, $\widehat{\beta}_1$.

Our estimate, $\widehat{\beta}_1$, is consistent, so by Slutsky's theorem, the sample residuals $\widehat{u}$ computed at this value of β will also be consistent. Using virtually the same arguments used to justify the Huber/Eicker/White heteroskedasticity-robust VCE, if we assume that the residuals are independent though not identically distributed, we can estimate $\mathbf{S}$ as

$$\widehat{\mathbf{S}} = \frac{1}{N}\sum_i \widehat{u}_i^2\mathbf{z}_i\mathbf{z}_i'$$

Then, in the second step, we re-solve (2), using $\widehat{\mathbf{W}}_2 = \widehat{\mathbf{S}}^{-1}$, yielding the two-step GMM estimate $\widehat{\beta}_2$. If the residuals exhibit clustering, you can specify `wmatrix(cluster` *varname*`)` so that `gmm` computes a weight matrix that does not assume the u_i's are independent within clusters identified by *varname*. You can specify `wmatrix(hac ...)` to obtain weight matrices that are suitable for when the u_i's exhibit autocorrelation as well as heteroskedasticity.

We could take the point estimates from the second round of estimation and use them to compute yet another weight matrix, $\widehat{\mathbf{W}}_3$, say, re-solve (2) yet again, and so on, stopping when the parameters or weight matrix do not change much from one iteration to the next. This procedure is known as the iterative GMM estimator and is obtained with the `igmm` option. Asymptotically, the two-step and iterative GMM estimators have the same distribution. However, Hall (2005, 90) suggests that the iterative estimator may have better finite-sample properties.

Instead of computing $\widehat{\mathbf{W}}_1$ as in (4), we could simply choose $\widehat{\mathbf{W}}_1 = \mathbf{I}$, the identity matrix. The initial estimate, $\widehat{\beta}_1$, would still be consistent. You can request this behavior by specifying the `winitial(identity)` option. However, if you specify all your moment equations of the form $E(\mathbf{z}u) = \mathbf{0}$, we recommend using the default `winitial(unadjusted)` instead; the rescaling of the moment conditions implied by using a homoskedastic initial weight matrix makes the numerical routines used to solve (2) more stable.

If you fit a model with more than one of the moment equations of the form $E\{h(\mathbf{z};\beta)\} = \mathbf{0}$, then you must use `winitial(identity)` or `winitial(unadjusted, independent)`. With moment equations of that form, you do not specify a list of instruments, and `gmm` cannot evaluate (4)—the matrix expression in parentheses would necessarily be singular, so it cannot be inverted.

▷ Example 3: Two-step linear GMM estimator

From the previous discussion and the comments in *Introduction*, we see that the linear 2SLS estimator is a one-step GMM estimator where we use the weight matrix defined in (4) that assumes the errors are i.i.d. If we use the 2SLS estimate of β to obtain the sample residuals, compute a new weight matrix based on those residuals, and then do a second step of GMM estimation, we obtain the linear two-step GMM estimator as implemented by `ivregress gmm`.

In example 3 of [R] **ivregress**, we fit the model of rental rates as discussed in example 2 above. We now allow the residuals to be heteroskedastic, though we will maintain our assumption that they are independent. We type

```
. gmm (rent - {xb:hsngval pcturban} - {b0}), inst(pcturban faminc reg2-reg4)
Step 1
Iteration 0:   GMM criterion Q(b) =   56115.03
Iteration 1:   GMM criterion Q(b) =  110.91583
Iteration 2:   GMM criterion Q(b) =  110.91583
Step 2
Iteration 0:   GMM criterion Q(b) =   .2406087
Iteration 1:   GMM criterion Q(b) =  .13672801
Iteration 2:   GMM criterion Q(b) =  .13672801
GMM estimation
Number of parameters =   3
Number of moments    =   6
Initial weight matrix: Unadjusted                 Number of obs   =       50
GMM weight matrix:     Robust
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
/xb_hsngval	.0014643	.0004473	3.27	0.001	.0005877	.002341
/xb_pcturban	.7615482	.2895105	2.63	0.009	.1941181	1.328978
/b0	112.1227	10.80234	10.38	0.000	90.95052	133.2949

```
Instruments for equation 1: pcturban faminc reg2 reg3 reg4 _cons
```

By default, `gmm` computes a heteroskedasticity-robust weight matrix before the second step of estimation, though we could have specified `wmatrix(robust)` if we wanted to be explicit. Because we did not specify the `vce()` option, `gmm` used a heteroskedasticity-robust one. Our results match those in example 3 of [R] **ivregress**. Moreover, the only difference between this example and the previous example of 2SLS is that here we did not use the `onestep` option.

◁

Obtaining standard errors

This section is a bit more theoretical and can be skipped on first reading. However, the information is sufficiently important that you should return to this section at some point.

So far in our discussion, we have focused on point estimation without much mention of how we obtain the standard errors of the estimates. We also mentioned that if we choose $\mathbf{W}$ to be the inverse of the covariance matrix of the moment conditions, then we obtain the "optimal" GMM estimator. We elaborate those points now.

Using mostly standard statistical arguments, we can show that for the GMM estimator defined in (2), the variance of $\widehat{\beta}$ is given by

$$\text{Var}(\widehat{\beta}) = \frac{1}{N}\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1}\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\mathbf{S}\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1} \tag{5}$$

where

$$\overline{\mathbf{G}}(\widehat{\beta}) = \frac{1}{N}\sum\nolimits_i \mathbf{z}_i \left.\frac{\partial u_i}{\partial \beta}\right|_{\beta=\widehat{\beta}} \qquad \text{or} \qquad \overline{\mathbf{G}}(\widehat{\beta}) = \frac{1}{N}\sum\nolimits_i \left.\frac{\partial \mathbf{h}_i}{\partial \beta}\right|_{\beta=\widehat{\beta}}$$

as the case may be and $\mathbf{S} = E(\mathbf{z}uu'\mathbf{z}')$.

Assuming the `vce(unadjusted)` option is not specified, `gmm` reports standard errors based on the robust variance matrix defined in (5). For the two-step estimator, $\mathbf{W}$ is the weight matrix requested using the `wmatrix()` option, and it is calculated based on the residuals obtained after the first estimation step. The second-step point estimates and residuals are obtained, and $\mathbf{S}$ is calculated based on the specification of the `vce()` option. For the iterated estimator, $\mathbf{W}$ is calculated based on the second-to-last round of estimation, while $\mathbf{S}$ is based on the residuals obtained after the last round of estimation. Computation of the covariance matrix for the one-step estimator is, perhaps surprisingly, more involved; we discuss the covariance matrix with the one-step estimator in the technical note at the end of this section.

If we choose the weight matrix to be the inverse of the covariance matrix of the moment conditions so that $\mathbf{W} = \mathbf{S}^{-1}$, then (5) simplifies substantially:

$$\text{Var}(\widehat{\beta}) = \frac{1}{N}\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1} \tag{6}$$

The GMM estimator constructed using this choice of weight matrix along with the covariance matrix in (6) is known as the "optimal" GMM estimator. One can show that if in fact $\mathbf{W} = \mathbf{S}^{-1}$, then the variance in (6) is smaller than the variance in (5) of any other GMM estimator based on the same moment conditions but with a different choice of weight matrix. Thus the optimal GMM estimator is also known as the efficient GMM estimator, because it has the smallest variance of any estimator based on the given moment conditions.

To obtain standard errors from `gmm` based on the optimal GMM estimator, you specify the `vce(unadjusted)` option. We call that VCE unadjusted because we do not recompute the residuals after estimation to obtain the matrix $\mathbf{S}$ required in (5) or allow for the fact that those residuals may not be i.i.d. Some statistical packages by default report standard errors based on (6) and offer standard errors based on (5) only as an option or not at all. While the optimal GMM estimator is theoretically appealing, Cameron and Trivedi (2005, 177) suggest that in finite samples it need not perform better than the GMM estimator that uses (5) to obtain standard errors.

❑ Technical note

Computing the covariance matrix of the parameters after using the one-step estimator is actually a bit more complex than after using the two-step or iterative estimators. We can illustrate most of the intricacies by using linear regression with moment conditions of the form $E\{\mathbf{x}(y - \mathbf{x}'\beta)\} = \mathbf{0}$.

If you specify `winitial(unadjusted)` and `vce(unadjusted)`, then the initial weight matrix will be computed as

$$\widehat{\mathbf{W}}_1 = \left(\frac{1}{N}\sum_i \mathbf{x}_i\mathbf{x}_i'\right)^{-1} \tag{7}$$

Moreover, for linear regression, we can show that

$$\overline{\mathbf{G}}(\widehat{\beta}) = \frac{1}{N}\sum_i \mathbf{x}_i\mathbf{x}_i'$$

so that (6) becomes

$$\begin{aligned}\mathrm{Var}(\widehat{\beta}) &= \frac{1}{N}\left\{\left(\frac{1}{N}\sum_i \mathbf{x}_i\mathbf{x}_i'\right)\left(\frac{1}{N}\sum_i \mathbf{x}_i\mathbf{x}_i'\right)^{-1}\left(\frac{1}{N}\sum_i \mathbf{x}_i\mathbf{x}_i'\right)\right\}^{-1}\\ &= \left(\sum_i \mathbf{x}_i\mathbf{x}_i'\right)^{-1}\\ &= (\mathbf{X}'\mathbf{X})^{-1}\end{aligned} \tag{8}$$

However, we know that the nonrobust covariance matrix for the OLS estimator is actually $\widehat{\sigma}^2(\mathbf{X}'\mathbf{X})^{-1}$. What is missing from (8) is the scalar $\widehat{\sigma}^2$, the estimated variance of the residuals. When you use the one-step estimator and specify `winitial(unadjusted)`, the weight matrix (7) does not include the $\widehat{\sigma}^2$ term because `gmm` does not have a consistent estimate of β from which it can then estimate σ^2. The point estimates are still correct, because multiplying the weight matrix by a scalar factor does not affect the solution to the minimization problem.

To circumvent this issue, if you specify `winitial(unadjusted)` and `vce(unadjusted)`, `gmm` uses the estimated $\widehat{\beta}$ (which is consistent) to obtain a new unadjusted weight matrix that does include the term $\widehat{\sigma}^2$ so that evaluating (6) will yield correct standard errors.

If you use the two-step or iterated GMM estimators, this extra effort is not needed to obtain standard errors because the first-step (and subsequent steps') estimate of β is consistent and can be used to estimate σ^2 or some other weight matrix based on the `wmatrix()` option. Straightforward algebra shows that this extra effort is also not needed if you request any type of adjusted (robust) covariance matrix with the one-step estimator.

A similar issue arises when you specify `winitial(identity)` and `vce(unadjusted)` with the one-step estimator. Again the solution is to compute an unadjusted weight matrix after obtaining $\widehat{\beta}$ so that (6) provides the correct standard errors.

We have illustrated the problem and solution using a single-equation linear model. However, the problem arises whenever you use the one-step estimator with an unadjusted VCE, regardless of the number of equations; and `gmm` handles all the details automatically. Computation of Hansen's J statistic presents an identical issue, and `gmm` takes care of that as well.

If you supply your own initial weight matrix by using `winitial(`*matname*`)`, then the standard errors (as well as the J statistic reported by `estat overid`) are based on that weight matrix. You should verify that the weight matrix you provide will yield appropriate statistics.

❑

Exponential (Poisson) regression models

Exponential regression models are frequently encountered in applied work. For example, they can be used as alternatives to linear regression models on log-transformed dependent variables, obviating the need for post-hoc transformations to obtain predicted values in the original metric of the dependent variable. When the dependent variable represents a discrete count variable, they are also known as Poisson regression models; see Cameron and Trivedi (1998).

For now, we consider models of the form

$$y = \exp(\mathbf{x}'\beta) + u \tag{9}$$

where u is a zero-mean additive error term so that $E(y) = \exp(\mathbf{x}'\beta)$. Because the error term is additive, if $\mathbf{x}$ represents strictly exogenous regressors, then we have the population moment condition

$$E[\mathbf{x}\{y - \exp(\mathbf{x}'\beta)\}] = \mathbf{0} \tag{10}$$

Moreover, because the number of parameters in the model is equal to the number of instruments, there is no point to using the two-step GMM estimator.

▷ Example 4: Exponential regression

Cameron and Trivedi (2010, 323) fit a model of the number of doctor visits based on whether the patient has private insurance, whether the patient has a chronic disease, gender, and income. Here we fit that model by using `gmm`. To allow for potential excess dispersion, we will obtain a robust VCE matrix, which is the default for `gmm` anyway. We type

```
. use http://www.stata-press.com/data/r12/docvisits
. gmm (docvis - exp({xb:private chronic female income}+{b0})),
> instruments(private chronic female income) onestep
Step 1
Iteration 0:   GMM criterion Q(b) =  16.853973
Iteration 1:   GMM criterion Q(b) =  2.2706472
Iteration 2:   GMM criterion Q(b) =  .19088097
Iteration 3:   GMM criterion Q(b) =  .00041101
Iteration 4:   GMM criterion Q(b) =  3.939e-09
Iteration 5:   GMM criterion Q(b) =  6.572e-19
GMM estimation
Number of parameters =   5
Number of moments    =   5
Initial weight matrix: Unadjusted                     Number of obs   =      4412
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]

```
Instruments for equation 1: private chronic female income _cons
```

Our point estimates agree with those reported by Cameron and Trivedi to at least six significant digits; the small discrepancies are attributable to different optimization techniques and convergence criteria being used by `gmm` and `poisson`. The standard errors differ by a factor of sqrt$(4412/4411)$ because `gmm` uses N in the denominator of the formula for the robust covariance matrix, while the robust covariance matrix estimator used by `poisson` uses $N - 1$.

◁

❑ Technical note

That the GMM and maximum likelihood estimators of the exponential regression model coincide is not a general property of these two classes of estimators. The maximum likelihood estimator solves the score equations

$$\frac{1}{N}\sum_{i=1}^{N}\frac{\partial \ln \ell_i}{\partial \beta} = \mathbf{0}$$

where l_i is the likelihood for the ith observation. These score equations can be viewed as the sample analogues of the population moment conditions

$$E\left\{\frac{\partial \ln \ell_i}{\partial \beta}\right\} = \mathbf{0}$$

establishing that maximum likelihood estimators represent a subset of the class of GMM estimators.

For the Poisson model,

$$\ln \ell_i = -\exp(\mathbf{x}_i'\beta) + y_i\mathbf{x}_i'\beta - \ln y_i!$$

so the score equations are

$$\frac{1}{N}\sum_{i=1}^{N}\mathbf{x}_i\{y_i - \exp(\mathbf{x}_i'\beta)\} = \mathbf{0}$$

which are just the sample moment conditions implied by (10) that we used in the previous example. That is why our results using `gmm` match Cameron and Trivedi's results using `poisson`.

On the other hand, an intuitive set of moment conditions to consider for GMM estimation of a probit model is

$$E[\mathbf{x}\{y - \Phi(\mathbf{x}'\beta)\}] = \mathbf{0}$$

where $\Phi()$ is the standard normal cumulative distribution function. Differentiating the likelihood function for the maximum likelihood probit estimator, we can show that the corresponding score equations are

$$\frac{1}{N}\sum_{i=1}^{N}\left[\mathbf{x}_i\left\{y_i\frac{\phi(\mathbf{x}_i'\beta)}{\Phi(\mathbf{x}_i'\beta)} - (1-y_i)\frac{\phi(\mathbf{x}_i'\beta)}{1-\Phi(\mathbf{x}_i'\beta)}\right\}\right] = \mathbf{0}$$

where $\phi()$ is the standard normal density function. These two moment conditions are not equivalent, so the maximum likelihood and GMM probit estimators are distinct.

❑

▷ Example 5: Comparison of GMM and maximum likelihood

Using the automobile dataset, here we fit a probit model of `foreign` on `gear_ratio`, `length`, and `headroom` using first the score equations and then the intuitive set of GMM equations. We type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. global xb "{b1}*gear_ratio + {b2}*length + {b3}*headroom + {b0}"
. global phi "normalden($xb)"
. global Phi "normal($xb)"
. gmm (foreign*$phi/$Phi - (1-foreign)*$phi/(1-$Phi)),
> instruments(gear_ratio length headroom) onestep
  (output omitted)
. estimates store ml
. gmm (foreign - $Phi), instruments(gear_ratio length headroom) onestep
  (output omitted)
. estimates store gmm
```

```
. estimates table ml gmm, b se
```

Variable	ml	gmm

b0		
_cons	-6.0222289	-5.8595615
	3.5594588	3.5188028

legend: b/se

The coefficients on `gear_ratio` and `length` are close for the two estimators. The GMM estimate of the coefficient on `headroom` is twice that of the maximum likelihood estimate, though the relatively large standard errors imply that this difference is not significant. You can verify that the coefficients in the column marked "`ml`" match those you would obtain using `probit`. We have not discussed the differences among standard errors based on the various GMM and maximum-likelihood covariance matrix estimators to avoid tedious algebra, though you can verify that the robust covariance matrix after one-step GMM estimation differs by only a finite-sample adjustment factor of $(N/N-1)$ from the robust covariance matrix reported by `probit`. Both the maximum likelihood and GMM probit estimators require the normality assumption, and the maximum likelihood estimator is efficient if that normality assumption is correct; therefore, in this particular example, there is no reason to prefer the GMM estimator.

◁

We can modify (10) easily to allow for endogenous regressors. Suppose that x_j is endogenous in the sense that $E(u|x_j) \neq 0$. Then (10) is no longer a valid moment condition. However, suppose we have some variables other than $\mathbf{x}$ such that $E(u|\mathbf{z}) = \mathbf{0}$. We can instead use the moment conditions

$$E(\mathbf{z}u) = E[\mathbf{z}\{y - \exp(\mathbf{x}'\beta)\}] = \mathbf{0} \tag{11}$$

As usual, if some elements of $\mathbf{x}$ are exogenous, then they should appear in $\mathbf{z}$ as well.

▷ Example 6: Exponential regression with endogenous regressors

Returning to the model discussed in example 4, here we treat `income` as endogenous; unobservable factors that determine a person's income may also affect the number of times a person visits a doctor. We use a person's age and race as instruments. These are valid instruments if we believe that age and race influence a person's income but do not have a direct impact on the number of doctor visits. (Whether this belief is justified is another matter; we test that belief in [R] **gmm postestimation**.) Because we have more instruments (seven) than parameters (five), we have an overidentified model. Therefore, the choice of weight matrix does matter. We will utilize the default two-step GMM estimator. In the first step, we will use a weight matrix that assumes the errors are i.i.d. In the second step, we will use a weight matrix that assumes heteroskedasticity. When you specify `twostep`, these are the defaults for the first- and second-step weight matrices, so we do not have to use the `winitial()` or `wmatrix()` options. We will again obtain a robust VCE, which is also the default. We type

```

Once we control for the endogeneity of income, we find that its coefficient has quadrupled in size. Additionally, access to private insurance has less of an impact on the number of doctor visits and gender has more of an impact.

◁

❑ Technical note

Although perhaps at first tempting, unlike the Poisson model, you cannot simply replace $\mathbf{x}$ in the moment conditions for the probit (or logit) model with a vector of instruments, $\mathbf{z}$, if you have endogenous regressors. See Wilde (2008).

❑

Mullahy (1997) considers a slightly more complicated version of the exponential regression model that incorporates nonadditive unobserved heterogeneity. His model can be written as

$$y_i = \exp(\mathbf{x}_i'\beta)\eta_i + \epsilon_i$$

where $\eta_i > 0$ is an unobserved heterogeneity term that may be correlated with $\mathbf{x}_i$. One result from his paper is that instead of using the additive moment condition (10), we can use the multiplicative moment condition

$$E\left\{\mathbf{z}\frac{y - \exp(\mathbf{x}'\beta)}{\exp(\mathbf{x}'\beta)}\right\} = E[\mathbf{z}\{y\exp(-\mathbf{x}'\beta) - 1\}] = \mathbf{0} \tag{12}$$

Windmeijer and Santos Silva (1997) discuss the use of additive versus multiplicative moment conditions with endogenous regressors and note that a set of instruments that satisfies the additive moment conditions will not also satisfy the multiplicative moment conditions. They remark that which to use is an empirical issue that can at least partially be settled by using the test of overidentifying restrictions that is implemented by `estat overid` after `gmm` to ascertain whether the instruments for a given model are valid. See [R] **gmm postestimation** for information on the test of overidentifying restrictions.

Specifying derivatives

By default, `gmm` calculates derivatives numerically, and the method used produces accurate results for the vast majority of applications. However, if you refit the same model repeatedly or else have the derivatives available, then `gmm` will run more quickly if you supply it with analytic derivatives.

When you use the interactive version of `gmm`, you specify derivatives using substitutable expressions in much the same way you specify the moment equations. There are three rules you must follow:

1. As with the substitutable expressions that define residual equations, you bind parameters of the model in braces: `{b0}`, `{param}`, etc.
2. You must specify a derivative for each parameter that appears in each moment equation. If a parameter does not appear in a moment equation, then you do not specify a derivative for that parameter in that moment equation.
3. If you declare a linear combination in an equation, then you specify a derivative with respect to that linear combination. `gmm` applies the chain rule to obtain the derivatives with respect to the individual parameters encompassed by that linear combination.

We illustrate with several examples.

▷ Example 7: Derivatives for a single-equation model

Consider a simple exponential regression model with one exogenous regressor and a constant term. We have

$$u = y - \exp(\beta_0 + \beta_1 x)$$

Now

$$\frac{\partial u}{\partial \beta_0} = -\exp(\beta_0 + \beta_1 x) \qquad \text{and} \qquad \frac{\partial u}{\partial \beta_1} = -x\exp(\beta_0 + \beta_1 x)$$

In Stata, we type

```
. gmm (docvis - exp({b0} + {b1}*income)), instruments(income)
> deriv(/b0 = -1*exp({b0} + {b1}*income))
> deriv(/b1 = -1*income*exp({b0}+{b1}*income)) onestep
Step 1
Iteration 0:   GMM criterion Q(b) =  9.1548611
Iteration 1:   GMM criterion Q(b) =  3.5146131
Iteration 2:   GMM criterion Q(b) =  .01344695
Iteration 3:   GMM criterion Q(b) =  3.690e-06
Iteration 4:   GMM criterion Q(b) =  4.606e-13
Iteration 5:   GMM criterion Q(b) =  1.502e-26
```

```
GMM estimation
Number of parameters =   2
Number of moments    =   2
Initial weight matrix: Unadjusted                     Number of obs   =      4412
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
/b0	1.204888	.0462355	26.06	0.000	1.114268	1.295507
/b1	.0046702	.0009715	4.81	0.000	.0027662	.0065743

```
Instruments for equation 1: income _cons
```

Notice how we specified the `derivative()` option for each parameter. We simply specified a slash, the name of the parameter, an equal sign, then a substitutable expression that represents the derivative. Because our model has only one residual equation, we do not need to specify equation numbers in the `derivative()` options.

◁

When you specify a linear combination of variables, your derivative should be with respect to the entire linear combination. For example, say we have the residual equation

$$u = y - \exp(\mathbf{x}'\beta + \beta_0)$$

for which we would type

```
. gmm (y - exp({xb: x1 x2 x3} + {b0}) ...
```

Then in addition to the derivative $\partial u/\partial\beta_0$, we are to compute and specify

$$\frac{\partial u}{\partial(\mathbf{x}'\beta)} = -\exp(\mathbf{x}'\beta + \beta_0)$$

Using the chain rule, $\partial u/\partial\beta_j = \partial u/\partial(\mathbf{x}'\beta) \times \partial(\mathbf{x}'\beta)/\partial\beta_j = -x_j\exp(\mathbf{x}'\beta + \beta_0)$. Stata does this last calculation automatically. It knows the variables in the linear combination, so all it needs is the derivative of the residual function with respect to the linear combination. This allows you to change the variables in your linear combination without having to change the derivatives.

▷ Example 8: Derivatives with a linear combination

We refit the model described in the example illustrating exponential regression with endogenous regressors, now providing analytic derivatives. We type

```
. gmm (docvis - exp({xb:private chronic female income}+{b0})),
> instruments(private chronic female age black hispanic)
> derivative(/xb = -1*exp({xb:} + {b0}))
> derivative(/b0 = -1*exp({xb:} + {b0}))
Step 1
Iteration 0:   GMM criterion Q(b) =  16.910173
Iteration 1:   GMM criterion Q(b) =  .82270871
Iteration 2:   GMM criterion Q(b) =  .21831995
Iteration 3:   GMM criterion Q(b) =  .12685934
Iteration 4:   GMM criterion Q(b) =  .12672369
Iteration 5:   GMM criterion Q(b) =  .12672365
Step 2
Iteration 0:   GMM criterion Q(b) =  .00234641
Iteration 1:   GMM criterion Q(b) =  .00215957
Iteration 2:   GMM criterion Q(b) =  .00215911
Iteration 3:   GMM criterion Q(b) =  .00215911
```

```
GMM estimation
Number of parameters =   5
Number of moments    =   7
Initial weight matrix: Unadjusted                 Number of obs   =      4412
GMM weight matrix:     Robust
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]

```
Instruments for equation 1: private chronic female age black hispanic _cons
```

In the first `derivative()` option, we specified the name of the linear combination, `xb`, instead of an individual parameter's name. We already declared the variables of our linear combination in the substitutable expression for the residual equation, so in our substitutable expressions for the derivatives, we can use the shorthand notation `{xb:}` to refer to it.

Our point estimates are identical to those we obtained earlier. The standard errors and confidence intervals differ by only trivial amounts.

◁

Exponential regression models with panel data

In addition to supporting cross-sectional and time-series data, `gmm` also works with panel-data models. Here we illustrate `gmm`'s panel-data capabilities by expanding our discussion of exponential regression models to allow for panel data. This also provides us the opportunity to demonstrate the moment-evaluator program version of `gmm`. Our discussion is based on Blundell, Griffith, and Windmeijer (2002). Also see Wooldridge (1999) for further discussion of nonlinear panel-data models.

First, we expand (9) for panel data. With individual heterogeneity term η_i, we have

$$E(y_{it}|\mathbf{x}_{it}, \eta_i) = \exp(\mathbf{x}_{it}'\beta + \eta_i) = \mu_{it}\nu_i$$

where $\mu_{it} = \exp(\mathbf{x}_{it}'\beta)$ and $\nu_i = \exp(\eta_i)$. Note that there is no constant term in this model because its effect cannot be disentangled from ν_i. With an additive idiosyncratic error term, we have the regression model

$$y_{it} = \mu_{it}\nu_i + \epsilon_{it}$$

We do not impose the assumption $E(\mathbf{x}_{it}\eta_i) = \mathbf{0}$, so η_i can be considered a fixed effect in the sense that it may be correlated with the regressors.

As discussed by Blundell, Griffith, and Windmeijer (2002), if $\mathbf{x}_{it}$ is strictly exogenous, meaning $E(\mathbf{x}_{it}\epsilon_{is}) = \mathbf{0}$ for all t and s, then we can estimate the parameters of the model by using the sample moment conditions

$$\sum_i \sum_t \mathbf{x}_{it}\left(y_{it} - \mu_{it}\frac{\overline{y}_i}{\overline{\mu}_i}\right) = \mathbf{0} \tag{13}$$

where $\overline{y}_i$ and $\overline{\mu}_i$ are the means of y_{it} and μ_{it} for panel i, respectively. Because $\overline{\mu}_i$ depends on the parameters of the model, it must be recomputed each time `gmm` needs to evaluate the residual equation. Therefore, we cannot use the substitutable expression version of `gmm`. Instead, we must use the moment-evaluator program version.

The moment-evaluator program version of gmm functions much like the function-evaluator program versions of nl and nlsur. The program you write is passed one or more variables to be filled in with the residuals evaluated at the parameter values specified in an option passed to your program. For the fixed-effects Poisson model with strictly exogenous regressors, our first crack at a function-evaluator program is

```
program gmm_poi
        version 12
        syntax varlist if, at(name)
        quietly {
                tempvar mu mubar ybar
                gen double `mu' = exp(x1*`at'[1,1] + x2*`at'[1,2]       ///
                                                   + x3*`at'[1,3]) `if'
                egen double `mubar' = mean(`mu') `if', by(id)
                egen double `ybar' = mean(y) `if', by(id)
                replace `varlist' = y - `mu'*`ybar'/`mubar' `if'
        }
end
```

You can save your program in an ado-file named *name*.ado, where *name* is the name you use for your program; here we would save the program in the ado-file gmm_poi.ado. Alternatively, if you are working from within a do-file, you can simply define the program before calling gmm. The syntax statement declares that we are expecting to receive a *varlist*, containing the names of variables whose values we are to replace with the values of the residual equations, and an if expression that will mark the estimation sample; because our model has one residual equation, *varlist* will consist of one variable. at() is a required option to our program, and it will contain the name of a matrix containing the parameter values at which we are to evaluate the residual equation. All moment-evaluator programs must accept the *varlist*, if condition, and at() option.

The first part of our program computes μ_{it}. In the model we will fit shortly, we have three regressors, named x1, x2, and x3. The `at' vector will have three elements, one for each of those variables. Notice that we included `if' at the end of each statement that affects variables to restrict the computations to the relevant estimation sample. The two egen statements compute $\overline{\mu}_i$ and $\overline{y}_i$; in the example dataset we will use shortly, the panel variable is named id, and for simplicity we hardcoded that variable into our program as well. Finally, we compute the residual equation, which is the portion of (13) bound in parentheses.

▷ Example 9: Panel poisson with strictly exogenous regressors

To fit our model, we type

```
. use http://www.stata-press.com/data/r12/poisson1
. gmm gmm_poi, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep
Step 1
Iteration 0:   GMM criterion Q(b) =   51.99142
Iteration 1:   GMM criterion Q(b) =  .04345191
Iteration 2:   GMM criterion Q(b) =  8.720e-06
Iteration 3:   GMM criterion Q(b) =  7.115e-13
Iteration 4:   GMM criterion Q(b) =  5.130e-27
```

```
GMM estimation
Number of parameters =   3
Number of moments    =   3
Initial weight matrix: Unadjusted                     Number of obs   =       409
                                      (Std. Err. adjusted for 45 clusters in id)
------------------------------------------------------------------------------
             |               Robust
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         /b1 |     1.94866   .1000265    19.48   0.000     1.752612    2.144709
         /b2 |    -2.966119  .0923592   -32.12   0.000    -3.14714    -2.785099
         /b3 |     1.008634  .1156561     8.72   0.000      .781952    1.235315
------------------------------------------------------------------------------
Instruments for equation 1: x1 x2 x3
```

All three of our regressors are strictly exogenous, so they can serve as their own regressors. There is no constant term in the model (it would be unidentified), so we exclude a constant term from our list of instruments. We have one residual equation as indicated by `nequations(1)`, and we have three parameters, named `b1`, `b2`, and `b3`. The order in which you declare parameters in the `parameters()` option determines the order in which they appear in the `'at'` vector in the moment-evaluator program. We specified `vce(cluster id)` to obtain standard errors that allow for correlation among observations within each panel.

◁

❑ Technical note

The program we just wrote is sufficient to fit the model to the `poisson1` dataset, but if we want to fit that model to other datasets, we would need to change the variable names and perhaps account for having a different number of parameters as well. With a bit more programming, advanced users can write a more general program to work with arbitrary datasets. Any options not understood by `gmm` are passed along to the moment-evaluator program, and we can take advantage of that feature to pass the name of the dependent variable, list of regressors, and panel identifier variable. A better version of `gmm_poi` would be

```
program gmm_poi2
        version 12
        syntax varlist if, at(name) myrhs(varlist)  ///
               mylhs(varlist) myidvar(varlist)
        quietly {
                tempvar mu mubar ybar
                gen double `mu' = 0 `if'
                local j = 1
                foreach var of varlist `myrhs' {
                        replace `mu' = `mu' + `var'*`at'[1,`j'] `if'
                        local j = `j' + 1
                }
                replace `mu' = exp(`mu')
                egen double `mubar' = mean(`mu') `if', by(`myidvar')
                egen double `ybar' = mean(`mylhs') `if', by(`myidvar')
                replace `varlist' = `mylhs' - `mu'*`ybar'/`mubar' `if'
        }
end
```

Our program now accepts three more options. Our call to gmm is

```
. gmm gmm_poi2, mylhs(y) myrhs(x1 x2 x3) myidvar(id) nequations(1)
> parameters(b1 b2 b3) instruments(x1 x2 x3, noconstant) vce(cluster id) onestep
```

With mylhs(), myrhs(), and myidvar(), we are now able to fit our model to any panel dataset we wish without having to modify the gmm_poi2 program. In the section *Details of moment-evaluator programs* below, we show how to incorporate weights and derivatives in moment-evaluator programs. ❑

When past values of the idiosyncratic error term affect the value of a regressor, we say that regressor is *predetermined*. When one or more regressors are predetermined, sample moment condition (10) is no longer valid. However, Chamberlain (1992) shows that a simple alternative is to consider moment conditions of the form

$$\sum_i \sum_{t=2}^{T} \mathbf{x}_{i,t-1} \left(y_{i,t-1} - \mu_{i,t-1} \frac{y_{it}}{\mu_{it}} \right) = \mathbf{0} \tag{14}$$

Also see Wooldridge (1997) and Windmeijer (2000) for other moment conditions that can be used with predetermined regressors.

▷ Example 10: Panel Poisson with predetermined regressors

Here we refit the previous model, treating all the regressors as predetermined and using the moment conditions in (14). Our moment-evaluator program is

```
program gmm_poipre
        version 12
        syntax varlist if, at(name) myrhs(varlist) mylhs(varlist)
        quietly {
                tempvar mu mubar ybar
                gen double `mu' = 0 `if'
                local j = 1
                foreach var of varlist `myrhs' {
                        replace `mu' = `mu' + `var'*`at'[1,`j'] `if'
                        local j = `j' + 1
                }
                replace `mu' = exp(`mu')
                replace `varlist' = L.`mylhs' - L.`mu'*`mylhs'/`mu' `if'
        }
end
```

As before, the first part of our program computes μ_{it}; the only difference is in how we compute the residual equation. We used lag-operator notation so that Stata properly handles gaps in our dataset. Equation (14) shows that we are to use the first lags of the regressors as instruments, so we type

```
. gmm gmm_poipre, mylhs(y) myrhs(x1 x2 x3) nequations(1) parameters(b1 b2 b3)
> instruments(L.(x1 x2 x3), noconstant) vce(cluster id) onestep
(obs = 364)

Step 1
Iteration 0:   GMM criterion Q(b) =  52.997808
Iteration 1:   GMM criterion Q(b) =  2.1678071
Iteration 2:   GMM criterion Q(b) =  .08716503
Iteration 3:   GMM criterion Q(b) =  .00007136
Iteration 4:   GMM criterion Q(b) =  4.699e-11
Iteration 5:   GMM criterion Q(b) =  1.932e-23

GMM estimation

Number of parameters =   3

```

Here, like earlier with strictly exogenous regressors, the number of instruments equals the number of parameters, so there is no gain to using the two-step or iterated estimators. However, if you do have more instruments than parameters, you will most likely want to use one of those other estimators instead.

◁

In the previous example, we used $\mathbf{x}_{i,t-1}$ as instruments. A more efficient GMM estimator would also use $\mathbf{x}_{i,t-2}, \mathbf{x}_{i,t-3}, \ldots, \mathbf{x}_{i,1}$ as instruments in period t as well. `gmm`'s `xtinstruments()` option allows you to specify instrument lists that grow as t increases. Later we discuss the `xtinstruments()` option in detail in the context of linear dynamic panel-data models.

When a regressor is contemporaneously correlated with the idiosyncratic error term, we say that regressor is endogenous. Windmeijer (2000) shows that here we can use the moment condition

$$\sum_i \sum_{t=3}^{T} \mathbf{x}_{i,t-2} \left(\frac{y_{it}}{\mu_{it}} - \frac{y_{i,t-1}}{\mu_{i,t-1}} \right)$$

Here we use the second lag of the endogenous regressor as an instrument. If a variable is strictly exogenous, it can of course serve as its own instrument.

▷ Example 11: Panel Poisson with endogenous regressors

Here we refit the model, treating `x3` as endogenous and `x1` and `x2` as strictly exogenous. Our moment-evaluator program is

```
program gmm_poiend
        version 12
        syntax varlist if, at(name) myrhs(varlist) mylhs(varlist)
        quietly {
                tempvar mu mubar ybar
                gen double `mu' = 0 `if'
                local j = 1
                foreach var of varlist `myrhs' {
                        replace `mu' = `mu' + `var'*`at'[1,`j'] `if'
                        local j = `j' + 1
                }
                replace `mu' = exp(`mu')
                replace `varlist' = `mylhs'/`mu' - L.`mylhs'/L.`mu' `if'
        }
end
```

Now we call gmm using x1, x2, and L2.x3 as instruments:

```
. use http://www.stata-press.com/data/r12/poisson2

As with the predetermined case previously, instead of using just $\mathbf{x}_{i,t-2}$ as an instrument, we could use all further lags of $\mathbf{x}_{it}$ as instruments as well.

◁

Rational-expectations models

Macroeconomic models typically assume that agents' expectations about the future are formed rationally. By rational expectations, we mean that agents use all information available when forming their forecasts, so the forecast error is uncorrelated with the information available when the forecast was made. Say that at time t, people make a forecast, $\widehat{y}_{t+1}$, of variable y in the next period. If Ω_t denotes all available information at time t, then rational expectations implies that $E\left\{(\widehat{y}_{t+1} - y_{t+1})|\Omega_t\right\} = 0$. If Ω_t denotes observable variables such as interest rates or prices, then this conditional expectation can serve as the basis of a moment condition for GMM estimation.

▷ Example 12: Fitting a Euler equation

In a well-known article, Hansen and Singleton (1982) consider a model of portfolio decision making and discuss parameter estimation using GMM. We will consider a simple example with one asset in which the agent can invest. A consumer wants to maximize the present value of his lifetime utility derived from consuming the good. On the one hand, the consumer is impatient, so he would rather consume today than wait until tomorrow. On the other hand, if he consumes less today, he can invest more of his money, earning more interest that he can then use to consume more of the good tomorrow. Thus there is a tradeoff between having his cake today or sacrificing a bit today to have more cake tomorrow.

If we assume a specific form for the agent's utility function, known as the constant relative-risk aversion utility function, we can show that the Euler equation is

$$E\left[\mathbf{z}_t\left\{1-\beta(1+r_{t+1})(c_{t+1}/c_t)^{-\gamma}\right\}\right]=\mathbf{0}$$

where β and γ are the parameters to estimate, r_t is the return to the financial asset, and c_t is consumption in period t. β measures the agent's discount factor. If β is near one, the agent is patient and is more willing to forgo consumption this period. If β is close to zero, the agent is less patient and prefers to consume more now. The parameter γ characterizes the agent's utility function. If γ equals one, the utility function is linear. As γ tends toward zero, the utility function tends toward $u=\log(c)$.

We have data on 3-month Treasury bills (r_t) and consumption expenditures (c_t). As instruments, we will use lagged rates of return and past growth rates of consumption. We will use the two-step estimator and a weight matrix that allows for heteroskedasticity and autocorrelation up to four lags with the Bartlett kernel. In Stata, we type

```
. use http://www.stata-press.com/data/r12/cr

```

The warning message at the top of the output appears because the forward operator in our substitutable expression says that residuals can be computed only for 239 observations; our dataset contains 240 observations. Our estimate of β is near one, in line with expectations and published results.

◁

System estimators

In many economic models, two or more variables are determined jointly through a system of simultaneous equations. Indeed, some of the earliest work in econometrics, including that of the Cowles Commission, was centered around estimation of the parameters of simultaneous equations. The 2SLS and IV estimators we have already discussed are used in some circumstances to estimate such parameters. Here we focus on the joint estimation of all the parameters of systems of equations, and we begin with the well-known three-stage least-squares (3SLS) estimator.

Recall that the 2SLS estimator is based on the moment conditions $E(\mathbf{z}u) = \mathbf{0}$. The 2SLS estimator can be used to estimate the parameters of one equation of a system of structural equations. Moreover, with the 2SLS estimator, we do not even need to specify the structural relationship among all the endogenous variables; we need to specify only the equation on which interest focuses and simply assume reduced-form relationships among the endogenous regressors of the equation of interest and the exogenous variables of the model. If we are willing to specify the complete system of structural equations, then assuming our model is correctly specified, by estimating all the equations jointly, we can obtain estimates that are more efficient than equation-by-equation 2SLS.

In [R] **reg3**, we fit a simple two-equation macroeconomic model:

$$\texttt{consump} = \beta_0 + \beta_1\texttt{wagepriv} + \beta_2\texttt{wagegovt} + \epsilon_1 \tag{15}$$

$$\texttt{wagepriv} = \beta_3 + \beta_4\texttt{consump} + \beta_5\texttt{govt} + \beta_6\texttt{capital1} + \epsilon_2 \tag{16}$$

where `consump` represents aggregate consumption; `wagepriv` and `wagegovt` are total wages paid by the private and government sectors, respectively; `govt` is government spending; and `capital1` is the previous period's capital stock. We are not willing to assume that ϵ_1 and ϵ_2 are independent, so we must treat both `consump` and `wagepriv` as endogenous. Suppose that a random shock makes ϵ_2 positive. Then by (16), `wagepriv` will be higher than it otherwise would. Moreover, ϵ_1 will either be higher or lower, depending on the correlation between it and ϵ_2. The shock to ϵ_2 has made both `wagepriv` and ϵ_1 move, implying that in (15) `wagepriv` is an endogenous regressor. A similar argument shows that `consump` is an endogenous regressor in the second equation. In our model, `wagegovt`, `govt`, and `capital1` are all exogenous variables.

Let $\mathbf{z}_1$ and $\mathbf{z}_2$ denote the instruments for the first and second equations, respectively; we will discuss what comprises them shortly. We have two sets of moment conditions:

$$E\left\{\begin{array}{c}\mathbf{z}_1(\texttt{consump} - \beta_0 - \beta_1\texttt{wagepriv} - \beta_2\texttt{wagegovt}) \\ \mathbf{z}_2(\texttt{wagepriv} - \beta_3 - \beta_4\texttt{consump} - \beta_5\texttt{govt} - \beta_6\texttt{capital1})\end{array}\right\} = \mathbf{0} \tag{17}$$

One of the defining characteristics of 3SLS is that the errors are homoskedastic conditional on the instrumental variables. Using this assumption, we have

$$E\left[\left\{\begin{array}{c}\mathbf{z}_1\epsilon_1 \\ \mathbf{z}_2\epsilon_2\end{array}\right\}\left\{\begin{array}{cc}\mathbf{z}_1'\epsilon_1 & \mathbf{z}_2'\epsilon_2\end{array}\right\}\right] = \left\{\begin{array}{cc}\sigma_{11}E(\mathbf{z}_1\mathbf{z}_1') & \sigma_{12}E(\mathbf{z}_1\mathbf{z}_2') \\ \sigma_{21}E(\mathbf{z}_2\mathbf{z}_1') & \sigma_{22}E(\mathbf{z}_2\mathbf{z}_2')\end{array}\right\} \tag{18}$$

where $\sigma_{ij} = \mathrm{cov}(\epsilon_i, \epsilon_j)$. Let $\mathbf{\Sigma}$ denote the 2×2 matrix with typical element σ_{ij}.

The second defining characteristic of the 3SLS estimator is that it uses all the exogenous variables as instruments for all equations; here $\mathbf{z}_1 = \mathbf{z}_2 = (\texttt{wagegovt}, \texttt{govt}, \texttt{capital1}, 1)$, where the 1 indicates a constant term. From our discussion on the weight matrix and two-step estimation, we want to use the sample analogue of the matrix inverse of the right-hand side of (18) as our weight matrix.

To implement the 3SLS estimator, we apparently need to know $\mathbf{\Sigma}$ or at least have a consistent estimator of it. The solution is to fit (15) and (16) by 2SLS, use the sample residuals $\widehat{\epsilon_1}$ and $\widehat{\epsilon_2}$ to estimate $\mathbf{\Sigma}$, then estimate the parameters of (17) via GMM by using the weight matrix just discussed.

▷ Example 13: 3SLS estimation

3SLS is easier to do using `gmm` than it sounds. The 3SLS estimator is a two-step GMM estimator. In the first step, we do the equivalent of 2SLS on each equation, and then we compute a weight matrix based on (18). Finally, we perform a second step of GMM with this weight matrix.

In Stata, we type

```
. use http://www.stata-press.com/data/r12/klein, clear

```

The `independent` suboption of the `winitial()` option tells `gmm` to assume that the residuals are independent across equations; this suboption sets $\sigma_{21} = \sigma_{12} = 0$ in (18). Assuming both homoskedasticity and cross-equation independence is equivalent to fitting the two equations of our model independently by 2SLS. The `wmatrix()` option controls how the weight matrix is computed based on the first-step parameter estimates before the second step of estimation; here we request a weight matrix that assumes conditional homoskedasticity but that does not impose the cross-equation independence like the initial weight matrix we used. In this example, we also illustrated how to

name equations and how equation names can be used in the `instruments()` option. Our results are identical to those in [R] **reg3**.

We could have specified our instruments with the syntax

```
instruments(wagegovt govt capital1)
```

because `gmm` uses the variables listed in the `instruments()` option for all equations unless you use the `equations()` suboption to restrict those variables to certain equations. However, we wanted to emphasize that the same instruments are being used for both equations; in a moment, we will discuss an estimator that does not use the same instruments in all equations.

◁

In the previous example, if we omit the `twostep` option, the resulting coefficients will be equivalent to equation-by-equation 2SLS, which Wooldridge (2010, 216) calls the "system 2SLS estimator". Eliminating the `twostep` option makes the `wmatrix()` option irrelevant, so that option can be eliminated as well.

So far, we have developed the traditional 3SLS estimator. Wooldridge (2010, chap. 8) discusses the "GMM 3SLS" estimator that extends the traditional 3SLS estimator by allowing for heteroskedasticity and different instruments for different equations.

Generalizing (18) to an arbitrary number of equations, we have

$$E\left(\mathbf{Z}'\epsilon\epsilon'\mathbf{Z}\right) = E\left(\mathbf{Z}'\mathbf{\Sigma}\mathbf{Z}\right) \tag{19}$$

where

$$\mathbf{Z} = \begin{bmatrix} \mathbf{z}_1 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{z}_2 & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{z}_m \end{bmatrix}$$

and $\mathbf{\Sigma}$ is now $m \times m$. Equation (19) is the multivariate analogue of a homoskedasticity assumption; for each equation, the error variance is constant for all observations, as is the covariance between any two equations' errors.

We can relax this homoskedasticity assumption by considering different weight matrices. For example, if we continue to assume that observations are independent but not necessarily identically distributed, then by specifying `wmatrix(robust)`, we would obtain a weight matrix that allows for heteroskedasticity:

$$\widehat{W} = \frac{1}{N}\sum_i \mathbf{Z}_i'\widehat{\epsilon}_i\widehat{\epsilon}_i'\mathbf{Z}_i$$

This is the weight matrix in Wooldridge's (2010, 218) Procedure 8.1, "GMM with Optimal Weighting Matrix". By default, `gmm` would report standard errors based on his covariance matrix (8.27); specifying `vce(unadjusted)` would provide the optimal GMM standard errors. If you have multiple observations for each individual or firm in your dataset, you could specify `wmatrix(cluster` *id*`)`, where *id* identifies individuals or firms. This would allow arbitrary within-individual correlation, though it does not account for an individual-specific fixed or random effect. In both cases, we would continue to use `winitial(unadjusted, independent)` so that the first-step estimates are the system 2SLS estimates.

Wooldridge (2010, sec. 9.6) discusses instances where it is necessary to use different instruments in different equations. The GMM 3SLS estimator with different instruments in different equations but with conditional homoskedasticity is what Hayashi (2000, 275) calls the "full-information instrumental

variables efficient" (FIVE) estimator. Implementing the FIVE estimator is easy with gmm. For example, say we have a two-equation system, where kids, age, income, and education are all valid instruments for the first equation; but education is not a valid instrument for the second equation. Then our syntax would take the form

```
gmm (<mexp_1>) (<mexp_2>), instruments(1:kids age income education)
     instruments(2:kids age income)
```

The following syntax is equivalent:

```
gmm (<mexp_1>) (<mexp_2>), instruments(kids age income)
     instruments(1:education)
```

Because we did not specify a list of equations in the second example's first instruments() option, those variables are used as instruments in both equations. You can use whichever syntax you prefer. The first requires a bit more typing but is arguably more transparent.

If all the regressors in the model are exogenous, then the traditional 3SLS estimator is the seemingly unrelated regression (SUR) estimator. Here you would specify all the regressors as instruments.

Dynamic panel-data models

Commands in Stata that work with panel data expect the data to be in the "long" format, meaning that each row of the dataset consists of one subobservation that is a member of a logical observation (represented by the panel identifier variable). See [D] **reshape** for a discussion of the long versus "wide" data forms. gmm is no exception in this respect when used with panel data. From a theoretical perspective, however, it is sometimes easier to view GMM estimators for panel data as system estimators in which we have N observations on a system of T equations, where N and T are the number of observations and panels, respectively, rather than a single-equation estimator with NT observations. Usually, each of the T equations will in fact be the same, though we will want to specify different instruments for each of these equations.

In a dynamic panel-data model, lagged values of the dependent variable are included as regressors. Here we consider a simple model with one lag of the dependent variable y as a regressor and a vector of strictly exogenous regressors, $\mathbf{x}_{it}$:

$$y_{it} = \rho y_{i,t-1} + \mathbf{x}_{it}'\beta + u_i + \epsilon_{it} \tag{20}$$

u_i can be either a fixed- or a random-effect term, in the sense that we do not require $\mathbf{x}_{it}$ to be independent of it. Even with the assumption that ϵ_{it} is i.i.d., the presence of both $y_{i,t-1}$ and u_i in (20) renders both the standard fixed- and random-effects estimators to be inconsistent because of the well-known Nickell (1981) bias. OLS regression of y_{it} on $y_{i,t-1}$ and $\mathbf{x}_{it}$ also produces inconsistent estimates, because $y_{i,t-1}$ will be correlated with the error term.

❑ Technical note

Stata has the xtabond, xtdpd, and xtdpdsys commands (see [XT] **xtabond**, [XT] **xtdpd**, and [XT] **xtdpdsys**) to fit equations like (20), and for everyday use those commands are preferred because they offer features such as Windmeijer (2005) bias-corrected standard errors to account for the bias of traditional two-step GMM standard errors seen in dynamic panel-data models and, being linear estimators, only require you to specify variable names instead of complete equations. However, using gmm has several pedagogical advantages, including the ability to tie those model-specific commands into a more general framework, a clear illustration of how certain types of instrument matrices for panel-data models are formed, and demonstrations of several advanced features of gmm.

❑

First-differencing (20) removes the panel-specific u_i term:

$$y_{it} - y_{i,t-1} = \rho(y_{i,t-1} - y_{i,t-2}) + (\mathbf{x}_{it} - \mathbf{x}_{i,t-1})'\beta + (\epsilon_{it} - \epsilon_{i,t-1}) \tag{21}$$

However, now $(y_{i,t-1} - y_{i,t-2})$ is correlated with $(\epsilon_{it} - \epsilon_{i,t-1})$. Thus we need an instrument that is correlated with the former but not the latter. The lagged variables in (21) mean that equation is not estimable for $t < 3$, so consider when $t = 3$. We have

$$y_{i3} - y_{i2} = \rho(y_{i2} - y_{i1}) + (\mathbf{x}_{i3} - \mathbf{x}_{i2})'\beta + (\epsilon_{i3} - \epsilon_{i2}) \tag{22}$$

In the Arellano–Bond (1991) estimator, lagged levels of the dependent variable are used as instruments. With our assumption that the ϵ_{it} are i.i.d., (20) intimates that y_{i1} can serve as an instrumental variable when we fit (22).

Next consider (21) when $t = 4$. We have

$$y_{i4} - y_{i3} = \rho(y_{i3} - y_{i2}) + (\mathbf{x}_{i4} - \mathbf{x}_{i3})'\beta + (\epsilon_{i4} - \epsilon_{i3})$$

Now (20) shows that both y_{i1} and y_{i2} are uncorrelated with the error term $(\epsilon_{i4} - \epsilon_{i3})$, so we have two instruments available. For $t = 5$, you can show that y_{i1}, y_{i2}, and y_{i3} can serve as instruments. As may now be apparent, one of the key features of these dynamic panel-data models is that the available instruments depend on the time period, t, as was the case for some of the panel Poisson models we considered earlier. Because the $\mathbf{x}_{it}$ are strictly exogenous by assumption, they can serve as their own instruments.

The initial weight matrix that is appropriate for the GMM dynamic panel-data estimator is slightly more involved than the unadjusted matrix we have used in most of our previous examples that assumes the errors are i.i.d. First, rewrite (21) for panel i as

$$\mathbf{y}_i - \mathbf{y}_i^L = \rho\,(\mathbf{y}_i^L - \mathbf{y}_i^{LL}) + (\mathbf{X}_i - \mathbf{X}_i^L)\beta + (\epsilon_i - \epsilon_i^L)$$

where $\mathbf{y}_i = (y_{i3}, \ldots, y_{iT})$ and $\mathbf{y}_i^L = (y_{i2}, \ldots, y_{i,T-1})$, $\mathbf{y}_i^{LL} = (y_{i1}, \ldots, y_{i,T-2})$, and $\mathbf{X}_i$, $\mathbf{X}_i^L$, ϵ_i, and ϵ_i^L are defined analogously. Let $\mathbf{Z}$ denote the full matrix of instruments for panel i, including the variables specified in both the `instruments()` and `xtinstruments()` options; the exact structure is detailed in *Methods and formulas*.

By assumption, ϵ_{it} is i.i.d., so the first-difference $(\epsilon_{it} - \epsilon_{i,t-1})$ is necessarily autocorrelated with correlation -0.5. Therefore, we should not use a weight matrix that assumes the errors are independent. For dynamic panel-data models, we can show that the appropriate initial weight matrix is

$$\widehat{\mathbf{W}} = \left(\frac{1}{N}\sum\nolimits_i \mathbf{Z}_i'\mathbf{H}_D\mathbf{Z}_i\right)^{-1}$$

where

$$\mathbf{H}_D = \begin{bmatrix} 1 & -0.5 & 0 & \ldots & 0 & 0 \\ -0.5 & 1 & -0.5 & \ldots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ldots & 1 & -0.5 \\ 0 & 0 & 0 & \ldots & -0.5 & 1 \end{bmatrix}$$

We can obtain this initial weight matrix by specifying `winitial(xt D)`. The letter `D` indicates that the equation we are estimating is specified in first-differences.

▷ Example 14: Arellano–Bond estimator

Say we want to fit the model

$$\mathtt{n}_{it} = \rho\,\mathtt{n}_{i,t-1} + \beta_1\mathtt{w}_{it} + \beta_2\mathtt{w}_{i,t-1} + \beta_3\mathtt{k}_{it} + \beta_4\mathtt{k}_{i,t-1} + u_i + \epsilon_{it} \tag{23}$$

where we assume that $\mathtt{w}_{it}$ and $\mathtt{k}_{it}$ are strictly exogenous. First-differencing, our residual equation is

$$\begin{aligned}\epsilon^*_{it} = (\epsilon_{it} - \epsilon_{i,t-1}) =& \mathtt{n}_{it} - \mathtt{n}_{i,t-1} - \rho\,(\mathtt{n}_{i,t-1} - \mathtt{n}_{i,t-2}) - \beta_1(\mathtt{w}_{it} - \mathtt{w}_{i,t-1}) \\ &- \beta_2(\mathtt{w}_{i,t-1} - \mathtt{w}_{i,t-2}) - \beta_3(\mathtt{k}_{it} - \mathtt{k}_{i,t-1}) - \beta_4(\mathtt{k}_{i,t-1} - \mathtt{k}_{i,t-2})\end{aligned} \tag{24}$$

In Stata, we type

        Standard: D.w LD.w D.k LD.k
```

Because `w` and `k` are strictly exogenous, we specified the variants of them that appear in (24) in the `instruments()` option; because there is no constant term in the model, we specified `noconstant` to omit the constant from the instrument list.

We specified `xtinstruments(n, lags(2/.))` to tell `gmm` what instruments to use for the lagged dependent variable included as a regressor in (23). Based on our previous discussion, lags two and higher of $\mathtt{n}_{it}$ can serve as instruments. The `lags(2/.)` suboption tells `gmm` that the first available instrument for $\mathtt{n}_{it}$ is the lag-two value $\mathtt{n}_{i,t-2}$. The "`.`" tells `gmm` to use all further lags of $\mathtt{n}_{it}$ as instruments as well. The instrument matrices in dynamic panel-data models can become large if the dataset has many time periods per panel. In those cases, you could specify, for example, `lags(2/4)` to use just lags two through four instead of using all available lags.

Our results are identical to those we would obtain using `xtabond` with the syntax

```
xtabond n L(0/1).w L(0/1).k, lags(1) noconstant vce(robust)
```

Had we left off the `vce(robust)` option in our call to `xtabond`, we would have had to specify `vce(unadjusted)` in our call to `gmm` to obtain the same standard errors.

◁

❑ Technical note

gmm automatically excludes observations for which there are no valid observations for the panel-style instruments. However, it keeps in the estimation sample those observations for which fewer than the maximum number of instruments you requested are available. For example, if you specify the lags(2/4) suboption, you have requested three instruments, but gmm will keep observations even if only one or two instruments are available.

❑

▷ Example 15: Two-step Arellano–Bond estimator

Here we refit the model in the previous example, using the two-step GMM estimator.

```
. gmm (D.n - {rho}*LD.n - {xb:D.w LD.w D.k LD.k}),
> xtinstruments(n, lags(2/.)) instruments(D.w LD.w D.k LD.k, noconstant)

```

Our results match those you would obtain with the command

```
xtabond n L(0/1).(w k), lags(1) noconstant twostep
```

◁

❑ Technical note

Had we specified vce(robust) in our call to gmm, we would have obtained the traditional sandwich-based robust covariance matrix, but our standard errors would not match those we would obtain by specifying vce(robust) with the xtabond command. The xtabond, xtdpd, and xtdpdsys commands implement a bias-corrected robust VCE for the two-step GMM dynamic panel-data estimator. Traditional VCEs computed after the two-step dynamic panel-data estimator have been shown to exhibit often-severe bias; see Windmeijer (2005).

❑

Neither of the two dynamic panel-data examples we have fit so far include a constant term. When a constant term is included, the dynamic panel-data estimator is in fact a two-equation system estimator. For notational simplicity, consider a simple model containing just a constant term and one lag of the dependent variable:

$$y_{it} = \alpha + \rho y_{i,t-1} + u_i + \epsilon_{it}$$

First-differencing to remove the u_i term, we have

$$y_{it} - y_{i,t-1} = \rho(y_{i,t-1} - y_{i,t-2}) + (\epsilon_{it} - \epsilon_{i,t-1}) \tag{25}$$

This has also eliminated the constant term. If we assume $E(u_i) = 0$, which is reasonable if a constant term is included in the model, then we can recover α by including the moment condition

$$y_{it} = \alpha + \rho y_{i,t-1} + \epsilon'_{it} \tag{26}$$

where $\epsilon'_{it} = u_i + \epsilon_{it}$. The parameter ρ continues to be identified by (25), so the only instrument we use with (26) is a constant term. As before, the error term $(\epsilon_{i,t} - \epsilon_{i,t-1})$ is necessarily autocorrelated with correlation coefficient -0.5, though the error term ϵ'_{it} is white noise. Therefore, our initial weight matrix should be

$$\widehat{\mathbf{W}} = \left(\frac{1}{N}\sum\nolimits_i \mathbf{Z}_i'\mathbf{H}\mathbf{Z}_i\right)^{-1}$$

where

$$\mathbf{H} = \begin{bmatrix} \mathbf{H}_D & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}$$

and $\mathbf{I}$ is a conformable identity matrix.

One complication arises concerning the relevant estimation sample. Looking at (25), we apparently lose the first two observations from each panel because of the presence of $y_{i,t-2}$, but in (26) we need only to sacrifice one observation, for $y_{i,t-1}$. For most multiple-equation models, we need to use the same estimation sample for all equations. However, in dynamic panel-data models, we can use more observations to fit the equation in level form [(26) here] than the equation in first-differences [equation (25)]. To request this behavior, we specify the `nocommonesample` option to `gmm`. That option tells `gmm` to use as many observations as possible for each equation, ignoring the loss of observations due to lagging or differencing.

▷ Example 16: Arellano–Bond estimator with constant term

Here we fit the model

$$\mathtt{n}_{it} = \alpha + \rho\,\mathtt{n}_{i,t-1} + u_i + \epsilon_{it}$$

Without specifying derivatives, our command would be

```
. gmm (D.n - {rho}*LD.n) (n - {alpha} - {rho}*L.n),
> xtinstruments(1: n, lags(2/.)) instruments(1:, noconstant) onestep
> winitial(xt DL) vce(unadj) nocommonesample
```

We would specify `winitial(xt DL)` to obtain the required initial weight matrix. The notation `DL` indicates that our first moment equation is in first-differences and the second moment equation is in levels (not first-differenced). We exclude a constant in the instrument list for the first equation, because first-differencing removed the constant term. Because we do not specify the `instruments()` option for the second moment equation, a constant is used by default.

This example also provides us the opportunity to illustrate how to specify derivatives for multiple-equation GMM models. Within the `derivative()` option, instead of specifying just the parameter name, now you must specify the equation name or number, a slash, and the parameter name to which the derivative applies. In Stata, we type

```
. gmm (D.n - {rho}*LD.n) (n - {alpha} - {rho}*L.n),
> xtinstruments(1: n, lags(2/.)) instruments(1:, noconstant)
> derivative(1/rho = -1*LD.n) derivative(2/alpha = -1)
> derivative(2/rho = -1*L.n) winitial(xt DL) vce(unadj) nocommonesample onestep
Step 1
Iteration 0:   GMM criterion Q(b) =  .09894466
Iteration 1:   GMM criterion Q(b) =  .00023508
Iteration 2:   GMM criterion Q(b) =  .00023508
GMM estimation

        XT-style: L(2/.).n
Instruments for equation 2:
        Standard: _cons
```

These results are identical to those we would obtain by typing

```
xtabond n, lags(1)
```

Because we specified `nocommonesample`, `gmm` did not report the number of observations used in the header of the output. In this dataset, there are in fact 1,031 observations on 140 panels. In the second equation, the presence of the lagged value of `n` reduces the sample size for that equation to $1031 - 140 = 891$. In the first equation, we lose the first two observations per panel due to lagging and differencing, leading to 751 usable observations. These tallies are listed after the coefficient table in the output.

◁

❑ Technical note

Specifying

```
xtinstruments(x1 x2 x3, lags(1/3))
```

differs from

```
instruments(L(1/3).(x1 x2 x3))
```

in how observations are excluded from the estimation sample. When you use the latter syntax, `gmm` must exclude the first three observations from each panel when computing the moment equation: you requested three lags of each regressor be used as instruments, so the first residual that could be interacted with those instruments is the one for $t = 4$. On the other hand, when you use `xtinstruments()`, you are telling `gmm` that you would like to use up to the first three lags of `x1`, `x2`, and `x3` as instruments

but that using just one lag is acceptable. Because most panel datasets have a relatively modest number of observations per panel, dynamic instrument lists are typically used so that the number of usable observations is maximized. Dynamic instrument lists also accommodate the fact that there are more valid instruments for later time periods than earlier time periods.

Specifying panel-style instruments using the `xtinstruments()` option also affects how the standard instruments specified in the `instruments()` option are treated. To illustrate, suppose we have a balanced panel dataset with $T = 5$ observations per panel and we specify

```
. gmm ..., xtinstruments(w, lags(1/2)) instruments(x)
```

We will lose the first observation because we need at least one lag of `w` to serve as an instrument. Our instrument matrix for panel i will therefore be

$$\mathbf{Z}_i = \begin{bmatrix} w_{i1} & 0 & 0 & 0 \\ 0 & w_{i1} & 0 & 0 \\ 0 & w_{i2} & 0 & 0 \\ 0 & 0 & w_{i2} & 0 \\ 0 & 0 & w_{i3} & 0 \\ 0 & 0 & 0 & w_{i3} \\ 0 & 0 & 0 & w_{i4} \\ x_{i2} & x_{i3} & x_{i4} & x_{i5} \\ 1 & 1 & 1 & 1 \end{bmatrix} \tag{27}$$

The vector of ones in the final row represents the constant term implied by the `instruments()` option. Because we lost the first observation, the residual vector $\mathbf{u}_i$ will be 4×1. Thus our moment conditions for the ith panel can be written in matrix notation as

$$E\{\mathbf{Z}_i \mathbf{u}_i(\beta)\} = E\left\{ \mathbf{Z}_i \begin{bmatrix} u_{i2}(\beta) \\ u_{i3}(\beta) \\ u_{i4}(\beta) \\ u_{i5}(\beta) \end{bmatrix} \right\} = \mathbf{0}$$

The moment conditions corresponding to the final two rows of (27) say that

$$E\left\{ \sum_{t=2}^{T=4} x_{it} u_{it}(\beta) \right\} = 0 \qquad \text{and} \qquad E\left\{ \sum_{t=2}^{T=4} u_{it}(\beta) \right\} = 0$$

Because we specified panel-style instruments with the `xtinstruments()` option, `gmm` no longer uses moment conditions for strictly exogenous variables of the form $E\{x_{it} u_{it}(\beta)\} = 0$ for each t. Instead, the moment conditions now stipulate that the average (over t) of $x_{it} u_{it}(\beta)$ has expectation zero. This corresponds to the approach proposed by Arellano and Bond (1991, 280) and others.

When you request panel-style instruments with the `xtinstruments()` option, the number of instruments in the $\mathbf{Z}_i$ matrix increases quadratically in the number of periods. The dynamic panel-data estimators we have discussed in this section are designed for datasets that contain a large number of panels and a modest number of time periods. When the number of time periods is large, estimators that use standard (non–panel-style) instruments are more appropriate.

❑

We have focused on the Arellano–Bond dynamic panel-data estimator because of its relative simplicity. gmm can additionally fit any models that can be formulated using the xtdpd and xtdpdsys commands; see [XT] **xtdpd** and [XT] **xtdpdsys**. The key is to determine the appropriate instruments to use for the level and difference equations. You may find it useful to fit a version of your model with those commands to determine what instruments and XT-style instruments to use. We conclude this section with an example using the Arellano–Bover/Blundell–Bond estimator.

▷ Example 17: Arellano–Bover/Blundell–Bond estimator

We fit a small model that includes one lag of the dependent variable n as a regressor as well as the contemporaneous and first lag of w, which we assume are strictly exogenous. We could fit our model using xtdpdsys using the syntax

```
xtdpdsys n L(0/1).w, lags(1) twostep
```

Applying virtually all the syntax issues we have discussed so far, the equivalent gmm command is

```
. gmm (n - {rho}*L.n - {w}*w - {lagw}*L.w - {c})
>     (D.n - {rho}*LD.n - {w}*D.w - {lagw}*LD.w),
>     xtinst(1: D.n, lags(1/1)) xtinst(2: n, lags(2/.))
>     inst(2: D.w LD.w, noconstant)
>     deriv(1/rho = -1*L.n)

Details of moment-evaluator programs

In examples 9, 10, and 11, we used moment-evaluator programs to evaluate moment conditions that could not be specified using the interactive version of `gmm`. In the technical note after example 9, we showed how to make our program accept optional arguments so that we could pass the name of our dependent and independent variables and panel identifier variable. Here we discuss how to make moment-evaluator programs accept weights and provide derivatives.

The complete specification for a moment-evaluator program's `syntax` statement is

```
syntax varlist if [weight], at(name) options [derivatives(varlist)]
```

The macro `'varlist'` contains the list of variables that we are to fill in with the values of our residual equations. The macro `'if'` represents an `if` condition that restricts the estimation sample. The macro `'at'` represents a vector containing the parameter values at which we are to evaluate our residual equations. `options` represent other options that you specify in your call to `gmm` and want to have passed to your moment-evaluator programs. In our previous examples, we included the `mylhs()`, `myrhs()`, and `myidvar()` options.

Two new elements of the `syntax` statement allow for weights and derivatives. `weight` specifies the types of weights your program allows. The interactive version of `gmm` allows for `fweight`s, `aweight`s, and `pweight`s. However, unless you explicitly allow your moment evaluator program to accept weights, you cannot specify weights in your call to `gmm` with the moment-evaluator program version.

The `derivatives()` option is used to pass to your program a set of variables that you are to fill in with the derivatives of your residual equations with respect to the parameters. Say you specify k parameters in the `nparameters()` or `parameters()` option and q equations in the `nequations()` or `equations()` option. Then `'derivatives'` will contain $k \times q$ variables. The first k variables are for the derivatives of the first residual equation with respect to the k parameters, the second k variables are for the derivatives of the second residual equation, and so on.

▷ Example 18: Panel Poisson with strictly exogenous regressors and derivatives

To focus on how to specify derivatives, we return to the simple moment-evaluator program we used in example 9, in which we had three regressors, and extend it to supply derivatives. The error equation corresponding to moment condition (13) is

$$u_{it}(\beta) = y_{it} - \mu_{it}\frac{\overline{y}_i}{\overline{\mu}_i}$$

where μ_{it}, $\overline{\mu}_i$, and $\overline{y}_i$ were defined previously. Now

$$\frac{\partial}{\partial \beta_j} u_{it}(\beta) = -\mu_{it}\frac{\overline{y}_i}{\overline{\mu}_i^2}\left(x_{it}^{(j)}\overline{\mu}_i - \frac{1}{T}\sum_{l=1}^{l=T} x_{il}^{(j)}\mu_{il}\right) \tag{28}$$

where $x_{it}^{(j)}$ represents the jth element of $\mathbf{x}_{it}$.

Our moment-evaluator program is

```
program gmm_poideriv
        version 12
        syntax varlist if, at(name) [derivatives(varlist)]
        quietly {
                // Calculate residuals as before
                tempvar mu mubar ybar
                gen double `mu' = exp(x1*`at'[1,1] + x2*`at'[1,2]       ///
                                                   + x3*`at'[1,3]) `if'
                egen double `mubar' = mean(`mu') `if', by(id)
                egen double `ybar' = mean(y) `if', by(id)
                replace `varlist' = y - `mu'*`ybar'/`mubar' `if'
                // Did -gmm- request derivatives?
                if "`derivatives'" == "" {
                        exit                    // no, so we are done
                }
                // Calculate derivatives
                // We need the panel means of x1*mu, x2*mu, and x3*mu
                tempvar work x1mubar x2mubar x3mubar
                generate double `work' = x1*`mu' `if'
                egen double `x1mubar' = mean(`work') `if', by(id)
                replace `work' = x2*`mu' `if'
                egen double `x2mubar' = mean(`work') `if', by(id)
                replace `work' = x3*`mu' `if'
                egen double `x3mubar' = mean(`work') `if', by(id)
                local d1: word 1 of `derivatives'
                local d2: word 2 of `derivatives'
                local d3: word 3 of `derivatives'
                replace `d1' = -1*`mu'*`ybar'/`mubar'^2*(x1*`mubar' - `x1mubar')
                replace `d2' = -1*`mu'*`ybar'/`mubar'^2*(x2*`mubar' - `x2mubar')
                replace `d3' = -1*`mu'*`ybar'/`mubar'^2*(x3*`mubar' - `x3mubar')
        }
end
```

The `derivatives()` option is made optional in the `syntax` statement by placing it in square brackets. If `gmm` needs to evaluate your moment equations but does not need derivatives at that time, then the `derivatives()` option will be empty. In our program, we check to see if that is the case, and, if so, `exit` without calculating derivatives. As is often the case with [R] **ml** as well, the portion of our program devoted to derivatives is longer than the code to compute the objective function.

The first part of our derivative code computes the term

$$\frac{1}{T}\sum_{l=1}^{l=T} x_{il}^{(j)}\mu_{il} \tag{29}$$

for $x_{it}^{(j)} =$ `x1`, `x2`, and, `x3`. The `` `derivatives' `` macro contains three variable names, corresponding to the three parameters of the `` `at' `` matrix. We extract those names into local macros `` `d1' ``, `` `d2' ``, and `` `d3' ``, and then fill in the variables those macros represent with the derivatives shown in (28).

With our program written, we fit our model by typing

```
. use http://www.stata-press.com/data/r12/poisson1

Instruments for equation 1: x1 x2 x3
```

Our results are identical to those in example 9. Another way to verify that our program calculates derivatives correctly would be to type

```
. gmm gmm_poideriv, nequations(1) parameters(b1 b2 b3)
>  instruments(x1 x2 x3, noconstant) vce(cluster id) onestep
```

Without the `hasderivatives` option, `gmm` will not request derivatives from your program, even if it contains code to compute them. If you have trouble obtaining convergence with the `hasderivatives` option but do not have trouble without that option, then you need to recheck your derivatives.

◁

In the technical note after example 9, we modified the `gmm_poi` program so that we could specify the name of our dependent variable and a list of regressors. Here is the analogous version that computes analytic derivatives:

```
program gmm_poideriv2
        version 12
        syntax varlist if, at(name) myrhs(varlist)                      ///
                           mylhs(varlist) myidvar(varlist)              ///
                           [ derivatives(varlist) ]
        quietly {
                tempvar mu mubar ybar
                gen double `mu' = 0 `if'
                local j = 1
                foreach var of varlist `myrhs' {
                        replace `mu' = `mu' + `var'*`at'[1,`j'] `if'
                        local j = `j' + 1
                }
                replace `mu' = exp(`mu')
                egen double `mubar' = mean(`mu') `if', by(`myidvar')
                egen double `ybar' = mean(`mylhs') `if', by(`myidvar')
                replace `varlist' = `mylhs' - `mu'*`ybar'/`mubar' `if'
                if "`derivatives'" == "" {
                        exit
                }
                tempvar work xmubar
                local j = 1
                foreach var of varlist `myrhs' {
                        generate double `work' = `var'*`mu' `if'
                        egen double `xmubar' = mean(`work') `if' `wt'`exp', ///
                                by(`myidvar')
                        local deriv : word `j' of `derivatives'
                        replace `deriv' = -1*`mu'*`ybar'/`mubar'^2*     ///
                                (`var'*`mubar' - `xmubar')
                        local `++j'
                        drop `work' `xmubar'
                }
        }
end
```

To use this program, we type

```
gmm gmm_poideriv2, mylhs(y) myrhs(x1 x2 x3)
        nequations(1) parameters(b1 b2 b3)
        instruments(x1 x2 x3, noconstant)
        vce(cluster id) myidvar(id) onestep
        hasderivatives
```

We obtain results identical to those shown in example 18.

Depending on your model, allowing your moment-evaluator program to accept weights may be as easy as modifying the `syntax` command to allow them, or it may require significantly more work. If your program uses only commands like `generate` and `replace`, then just modifying the `syntax` command is all you need to do; `gmm` takes care of applying the weights to the observation-level residuals when computing the sample moments, derivatives, and weight matrices. On the other hand, if your moment-evaluator program computes residuals using statistics that depend on multiple observations, then you must apply the weights passed to your program when computing those statistics.

In our examples of panel Poisson with strictly exogenous regressors, we used the statistics $\overline{\mu}_i$ and $\overline{y}_i$ when computing the residuals. If we are to allow weights with our moment-evaluator program, then we must incorporate those weights when computing $\overline{\mu}_i$ and $\overline{y}_i$. Moreover, looking at the derivative in (28), the term highlighted in (29) is in fact a sample mean, so we must incorporate weights when computing it.

▷ Example 19: Panel Poisson with derivatives and weights

Here we modify the program in example 18. to accept frequency weights. One complication immediately arises: we had been using `egen` to compute $\overline{\mu}_i$ and $\overline{y}_i$. `egen` does not accept weights, so we must compute $\overline{\mu}_i$ and $\overline{y}_i$ ourselves, incorporating any weights the user may specify. Our program is

```
program gmm_poiderivfw
        version 12
        syntax varlist if [fweight/], at(name) [derivatives(varlist)]
        quietly {
                if "`exp'" == "" {        // no weights
                        local exp 1       // weight each observation equally
                }
                // Calculate residuals as before
                tempvar mu mubar ybar sumwt
                gen double `mu' = exp(x1*`at'[1,1] + x2*`at'[1,2]      ///
                                                   + x3*`at'[1,3]) `if'
                bysort id: gen double `sumwt' = sum(`exp')
                by id: gen double `mubar' = sum(`mu'*`exp')
                by id: gen double `ybar' = sum(y*`exp')
                by id: replace `mubar' = `mubar'[_N] / `sumwt'[_N]
                by id: replace `ybar' = `ybar'[_N] / `sumwt'[_N]
                replace `varlist' = y - `mu'*`ybar'/`mubar' `if'
                // Did -gmm- request derivatives?
                if "`derivatives'" == "" {
                        exit        // no, so we are done
                }
                // Calculate derivatives
                // We need the panel means of x1*mu, x2*mu, and x3*mu
                tempvar work x1mubar x2mubar x3mubar
                generate double `work' = x1*`mu' `if'
                by id: generate double `x1mubar' = sum(`work'*`exp')
                by id: replace `x1mubar' = `x1mubar'[_N] / `sumwt'[_N]
                replace `work' = x2*`mu' `if'
                by id: generate double `x2mubar' = sum(`work'*`exp')
                by id: replace `x2mubar' = `x2mubar'[_N] / `sumwt'[_N]
                replace `work' = x3*`mu' `if'
                by id: generate double `x3mubar' = sum(`work'*`exp')
                by id: replace `x3mubar' = `x3mubar'[_N] / `sumwt'[_N]
                local d1: word 1 of `derivatives'
                local d2: word 2 of `derivatives'
                local d3: word 3 of `derivatives'
                replace `d1' = -1*`mu'*`ybar'/`mubar'^2*(x1*`mubar' - `x1mubar')
                replace `d2' = -1*`mu'*`ybar'/`mubar'^2*(x2*`mubar' - `x2mubar')
                replace `d3' = -1*`mu'*`ybar'/`mubar'^2*(x3*`mubar' - `x3mubar')
        }
end
```

Our `syntax` command now indicates that `fweights` are allowed. The first part of our code looks at the macro `` `exp' ``. If it is empty, then the user did not specify weights in their call to `gmm`; and we set the macro equal to 1, so that we weight each observation equally. After we compute μ_{it}, we calculate $\overline{\mu}_i$ and $\overline{y}_i$, taking into account weights. To compute frequency-weighted means for each panel, we just multiply each observation by its respective weight, sum over all observations in the panel, then divide by the sum of the weights for the panel. (See [U] **20.22 Weighted estimation** for information on how to handle `aweights` and `pweights`.) We use the same procedure to compute the frequency-weighted variant of expression (29) in the derivative calculations.

To use our program, we type

```

Testing whether our program works correctly with frequency weights is easy. A frequency-weighted dataset is just a compact form of a larger dataset in which identical observations are omitted and a frequency-weight variable is included to tell us how many times each observation in the smaller dataset appears in the larger dataset. Therefore, we can `expand` our smaller dataset by the frequency-weight variable and then refit our model without specifying frequency weights. If we obtain the same results, our program works correctly. When we type

```
. expand fw
(410 observations created)
. gmm gmm_poiderivfw, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep
```

we obtain the same results as before.

◁

Saved results

gmm saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_aux)	number of auxiliary parameters
e(n_moments)	number of moments
e(n_eq)	number of equations in moment-evaluator program
e(Q)	criterion function
e(J)	Hansen J χ^2 statistic
e(J_df)	J statistic degrees of freedom
e(k_*i*)	number of parameters in equation i
e(has_xtinst)	1 if panel-style instruments specified, 0 otherwise
e(N_clust)	number of clusters
e(type)	1 if interactive version, 2 if moment-evaluator program version
e(rank)	rank of e(V)
e(ic)	number of iterations used by iterative GMM estimator
e(converged)	1 if converged, 0 otherwise

e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

gmm is implemented as an ado-file.

Let q denote the number of moment equations. For observation i, $i = 1, \ldots, N$, write the jth moment equation as $\mathbf{z}_{ij}u_{ij}(\beta_j)$ for $j = 1, \ldots, q$. $\mathbf{z}_{ij}$ is a $1 \times m_j$ vector, where m_j is the number of instruments specified for equation j. Let $m = m_1 + \cdots + m_q$.

Our notation can incorporate moment conditions of the form $h_{ij}(\mathbf{w}_{ij}; \beta_j)$ with instruments $\mathbf{w}_{ij}$ by defining $\mathbf{z}_{ij} = 1$ and $u_{ij}(\beta_j) = h_{ij}(\mathbf{w}_{ij}; \beta_j)$, so except when necessary we do not distinguish between the two types of moment conditions. We could instead use notation so that all our moment conditions are of the form $h_{ij}(\mathbf{w}_{ij}; \beta_j)$, or we could adopt notation that explicitly combines both forms of moment equations. However, because moment conditions of the form $\mathbf{z}'_{ij}u_{ij}(\beta_j)$ are arguably more common, we use that notation.

Let β denote a $k \times 1$ vector of parameters, consisting of all the unique parameters of $\beta_1, \ldots, \beta_q$. Then we can stack the moment conditions and write them more compactly as $\mathbf{Z}'_i\mathbf{u}_i(\beta)$, where

$$\mathbf{Z}_i = \begin{bmatrix} \mathbf{z}_{i1} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{z}_{i2} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{z}_{iq} \end{bmatrix} \quad \text{and} \quad \mathbf{u}_i(\beta) = \begin{bmatrix} u_{i1}(\beta_1) \\ u_{i2}(\beta_2) \\ \vdots \\ u_{iq}(\beta_j) \end{bmatrix}$$

The GMM estimator $\widehat{\beta}$ is the value of β that minimizes

$$Q(\beta) = \left\{ N^{-1} \sum_{i=1}^{N} \mathbf{Z}'_i\mathbf{u}_i(\beta) \right\}' \mathbf{W} \left\{ N^{-1} \sum_{i=1}^{N} \mathbf{Z}'_i\mathbf{u}_i(\beta) \right\} \tag{A1}$$

for $q \times q$ weight matrix $\mathbf{W}$.

By default, gmm minimizes (A1) using the Gauss–Newton method. See Hayashi (2000, 498) for a derivation. This technique is typically faster than quasi-Newton methods and does not require second-order derivatives.

Methods and formulas are presented under the following headings:

Initial weight matrix
Weight matrix
Variance–covariance matrix
Hansen's J statistic
Panel-style instruments

Initial weight matrix

If you specify `winitial(identity)`, then we set $\mathbf{W} = \mathbf{I}_q$.

If you specify `winitial(unadjusted)`, then we create matrix $\mathbf{\Lambda}$ with typical submatrix

$$\mathbf{\Lambda}_{rs} = N^{-1} \sum_{i=1}^{N} \mathbf{z}'_{ir}\mathbf{z}_{is}$$

for $r = 1, \ldots, q$ and $s = 1, \ldots, q$. If you include the `independent` suboption, then we set $\mathbf{\Lambda}_{rs} = \mathbf{0}$ for $r \neq s$. The weight matrix $\mathbf{W}$ equals $\mathbf{\Lambda}^{-1}$.

If you specify `winitial(`*matname*`)`, then we set $\mathbf{W}$ equal to Stata matrix *matname*.

If you specify `winitial(xt` *xtspec*`)`, then you must specify one or two items in *xtspec*, one for each equation. `gmm` allows you to specify at most two moment equations when you specify `winitial(xt` *xtspec*`)`, one in first-differences and one in levels. We create the block-diagonal matrix $\mathbf{H}$ with typical block $\mathbf{H}_j$. If the jth element of *xtspec* is "L", then $\mathbf{H}_j$ is the identity matrix of suitable dimension. If the jth element of *xtspec* is "D", then

$$\mathbf{H}_j = \begin{bmatrix} 1 & -0.5 & 0 & \dots & 0 & 0 \\ -0.5 & 1 & -0.5 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -0.5 \\ 0 & 0 & 0 & \dots & -0.5 & 1 \end{bmatrix}$$

Then

$$\mathbf{\Lambda}_H = N_g^{-1} \sum_{g=1}^{g=N_G} \mathbf{Z}_g' \mathbf{H} \mathbf{Z}_g$$

where g indexes panels in the dataset, N_G is the number of panels, $\mathbf{Z}_g$ is the full instrument matrix for panel g, and $\mathbf{W} = \mathbf{\Lambda}_H^{-1}$. See *Panel-style instruments* below for a discussion of how $\mathbf{Z}_g$ is formed.

Weight matrix

Specification of the weight matrix applies only to the two-step and iterative estimators. When you use the `onestep` option, the `wmatrix()` option is ignored.

We first evaluate (A1) using the initial weight matrix described above and then compute $\mathbf{u}_i(\widehat{\beta})$. In all cases, $\mathbf{W} = \mathbf{\Lambda}^{-1}$. If you specify `wmatrix(unadjusted)`, then we create $\mathbf{\Lambda}$ to have typical submatrix

$$\mathbf{\Lambda}_{rs} = \sigma_{rs}\, N^{-1} \sum_{i=1}^{N} \mathbf{z}_{ir}' \mathbf{z}_{is}$$

where

$$\sigma_{rs} = N^{-1} \sum_{i=1}^{N} u_{ir}(\widehat{\beta}) u_{is}(\widehat{\beta})$$

and r and s index moment equations. For all types of weight matrices, if the `independent` suboption is specified, then $\mathbf{\Lambda}_{rs} = \mathbf{0}$ for $r \neq s$, where $\mathbf{\Lambda}_{rs}$ measures the covariance between moment conditions for equations r and s.

If you specify `wmatrix(robust)`, then

$$\mathbf{\Lambda} = N^{-1} \sum_{i=1}^{N} \mathbf{Z}_i \mathbf{u}_i(\widehat{\beta}) \mathbf{u}_i'(\widehat{\beta}) \mathbf{Z}_i'$$

If you specify `wmatrix(cluster` *clustvar*`)`, then

$$\mathbf{\Lambda} = N^{-1} \sum_{c=1}^{c=N_C} \mathbf{q}_c \mathbf{q}_c'$$

where c indexes clusters, N_C is the number of clusters, and

$$\mathbf{q}_c = \sum_{i \in c_j} \mathbf{Z}_i \mathbf{u}_i(\widehat{\beta})$$

If you specify `wmatrix(hac` *kernel* `[#])`, then

$$\begin{aligned}\mathbf{\Lambda} =& N^{-1} \sum_{i=1}^{N} \mathbf{Z}_i \mathbf{u}_i(\widehat{\beta}) \mathbf{u}_i(\widehat{\beta})' \mathbf{Z}_i' \quad + \\ & N^{-1} \sum_{l=1}^{l=n-1} \sum_{i=l+1}^{N} K(l,m) \left\{ \mathbf{Z}_i \mathbf{u}_i(\widehat{\beta}) \mathbf{u}_{i-l}'(\widehat{\beta}) \mathbf{Z}_{i-l}' + \mathbf{Z}_{i-l} \mathbf{u}_{i-l}(\widehat{\beta}) \mathbf{u}_i'(\widehat{\beta}) \mathbf{Z}_i' \right\}\end{aligned}$$

where $m = \#$ if # is specified and $m = N - 2$ otherwise. Define $z = l/(m+1)$. If *kernel* is `bartlett` or `nwest`, then

$$K(l,m) = \begin{cases} 1 - z & 0 \le z \le 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `parzen` or `gallant`, then

$$K(l,m) = \begin{cases} 1 - 6z^2 + 6z^3 & 0 \le z \le 0.5 \\ 2(1-z)^3 & 0.5 < z \le 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `quadraticspectral` or `andrews`, then

$$K(l,m) = \begin{cases} 1 & z = 0 \\ 3\{\sin(\theta)/\theta - \cos(\theta)\}/\theta^2 & \text{otherwise} \end{cases}$$

where $\theta = 6\pi z/5$.

If `wmatrix(hac` *kernel* `opt)` is specified, then `gmm` uses Newey and West's (1994) automatic lag-selection algorithm, which proceeds as follows. Define $\mathbf{h}$ to be an $m \times 1$ vector of ones. Note that this definition of $\mathbf{h}$ is slightly different than the one used by `ivregress`. There, the element of $\mathbf{h}$ corresponding to the constant term equals zero, effectively ignoring the effect of the constant in determining the optimal lag length. Here we include the effect of the constant term. Now define

$$\begin{aligned} f_i &= \{\mathbf{Z}_i' \mathbf{u}_i(\beta)\}' \mathbf{h} \\ \widehat{\sigma}_j &= N^{-1} \sum_{i=j+1}^{N} f_i f_{i-j} \qquad j = 0, \ldots, m^* \\ \widehat{s}^{(q)} &= 2 \sum_{j=1}^{j=m^*} \widehat{\sigma}_j j^q \\ \widehat{s}^{(0)} &= \widehat{\sigma}_0 + 2 \sum_{j=1}^{j=m^*} \widehat{\sigma}_j \\ \widehat{\gamma} &= c_\gamma \left\{ \left(\frac{\widehat{s}^{(q)}}{\widehat{s}^{(0)}} \right)^2 \right\}^{1/(2q+1)} \\ m &= \widehat{\gamma} N^{1/(2q+1)} \end{aligned}$$

where q, m^*, and c_γ depend on the kernel specified:

Kernel	q	m^*	c_γ
Bartlett/Newey–West	1	int $\{20(T/100)^{2/9}\}$	1.1447
Parzen/Gallant	2	int $\{20(T/100)^{4/25}\}$	2.6614
Quadratic spectral/Andres	2	int $\{20(T/100)^{2/25}\}$	1.3221

where int(x) denotes the integer obtained by truncating x toward zero. For the Bartlett and Parzen kernels, the optimal lag is min$\{$int$(m), m^*\}$. For the quadratic spectral kernel, the optimal lag is min$\{m, m^*\}$.

Variance–covariance matrix

If you specify `vce(unadjusted)`, then the VCE matrix is computed as

$$\text{Var}(\widehat{\beta}) = N^{-1}\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1} \tag{A2}$$

where

$$\overline{\mathbf{G}}(\widehat{\beta}) = N^{-1}\sum_{i=1}^{N}\mathbf{Z}_i'\left.\frac{\partial \mathbf{u}_i(\beta)}{\partial \beta'}\right|_{\beta=\widehat{\beta}}$$

For the two-step and iterated estimators, we use the weight matrix $\mathbf{W}$ that was used to compute the final-round estimate $\widehat{\beta}$.

For the one-step estimator, how the unadjusted VCE is computed depends on the type of initial weight matrix requested and the form of the moment equations. If you specify two or more moment equations of the form $h_{ij}(\mathbf{w}_{ij};\beta_j)$, then `gmm` issues a warning message and computes a heteroskedasticity-robust VCE because here the matrix $\mathbf{Z}'\mathbf{Z}$ is necessarily singular; moreover, here you must use the identity matrix as the initial weight matrix. Otherwise, if you specify `winitial(identity)` or `winitial(unadjusted)`, then `gmm` first computes an unadjusted weight matrix based on $\widehat{\beta}$ before evaluating (A2). If you specify `winitial(`*matname*`)`, then (A2) is evaluated based on *matname*; the user is responsible for verifying that the VCE and other statistics so produced are appropriate.

All types of robust VCEs computed by `gmm` take the form

$$\text{Var}(\widehat{\beta}) = N^{-1}\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1}\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\mathbf{S}\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\left\{\overline{\mathbf{G}}(\widehat{\beta})'\mathbf{W}\overline{\mathbf{G}}(\widehat{\beta})\right\}^{-1}$$

For the one-step estimator, $\mathbf{W}$ represents the initial weight matrix requested using the `winitial()` option, and $\mathbf{S}$ is computed based on the specification of the `vce()` option. The formulas for the $\mathbf{S}$ matrix are identical to the ones that define the $\mathbf{\Lambda}$ matrix in *Weight matrix* above, except that $\mathbf{S}$ is computed after the moment equations are reevaluated using the final estimate of $\widehat{\beta}$. For the two-step and iterated GMM estimators, computation of $\mathbf{W}$ is controlled by the `wmatrix()` option based on the penultimate estimate of $\widehat{\beta}$.

For details on computation of the VCE matrix with dynamic panel-data models, see *Panel-style instruments* below.

Hansen's J statistic

Hansen's (1982) J test of overidentifying restrictions is $J = N \times Q(\widehat{\beta})$. $J \sim \chi^2(m-k)$. If $m < k$, `gmm` issues an error message without estimating the parameters. If $m = k$, the model is just-identified and J is saved as missing ("."). For the two-step and iterated GMM estimators, the J statistic is based on the last-computed weight matrix as determined by the `wmatrix()` option. For the one-step estimator, `gmm` recomputes a weight matrix as described in the second paragraph of *Variance–covariance matrix* above. To obtain Hansen's J statistic, you use `estat overid`; see [R] **gmm postestimation**.

Panel-style instruments

Here we discuss several issues that arise only when you specify panel-style instruments by using the `xtinstruments()` option. When you specify the `xtinstruments()` option, we can no longer consider the instruments for one observation in isolation; instead, we must consider the instrument matrix for an entire panel at once. In the following discussion, we let T denote the number of time periods in a panel. To accommodate unbalanced datasets, conceptually we simply use zeros as instruments and residuals for time periods that are missing in a panel.

We consider the case where you specify both an equation in levels and an equation in differences, yielding two residual equations. Let $u^L_{pt}(\beta)$ denote the residual for the level equation for panel p in period t, and let $u^D_{pt}(\beta)$ denote the residual for the corresponding difference equation. Now define the $2T \times 1$ vector $\mathbf{u}_p(\beta)$ as

$$\mathbf{u}_p(\beta) = [u^L_{p1}(\beta), u^L_{p2}(\beta), \ldots, u^L_{pT}(\beta), u^D_{p2}(\beta), u^D_{p3}(\beta), \ldots, u^D_{pT}(\beta)]$$

The $T+1$ element of $\mathbf{u}_p$ is $u^D_{p2}(\beta)$ since we lose the first observation of the difference equation because of differencing.

We write the moment conditions for the pth panel as $\mathbf{Z}_p\mathbf{u}_p(\beta)$. To see how $\mathbf{Z}_p$ is defined, let $\mathbf{w}^L_{pt}$ and $\mathbf{w}^D_{pt}$ denote the vectors of panel-style instruments for the level and difference equations, respectively, and let time be denoted by t; we discuss their dimensions momentarily. Also let $\mathbf{x}^L_{pt}$ and $\mathbf{x}^D_{pt}$ denote the vectors of instruments specified in `instruments()` for the level and difference equations at time t. Without loss of generality, for our discussion we assume that you specify the level equation first. Then $\mathbf{Z}_p$ has the form

$$\mathbf{Z}_p = \begin{bmatrix}
\mathbf{w}^L_1 & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{0} & \mathbf{w}^L_2 & \cdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{w}^L_T & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{x}^L_1 & \mathbf{x}^L_2 & \cdots & \mathbf{x}^L_T & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{w}^D_1 & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} & \mathbf{w}^D_2 & \cdots & \mathbf{0} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{w}^D_T \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{x}^D_1 & \mathbf{x}^D_2 & \cdots & \mathbf{x}^D_T
\end{bmatrix} \tag{A3}$$

To see how the $\mathbf{w}$ vectors are formed, suppose you specify

```
xtinstruments(eq(1): d, lags(a/b))
```

Then $\mathbf{w}_t^L$ will be a $(b-a+1)\times 1$ vector consisting of $d_{t-a},\ldots,d_{t-b}$. If $(t-a)\leq 0$, then instead we set $\mathbf{w}_t^L=0$. If $(t-a)>0$ but $(t-b)\leq 0$, then we create $\mathbf{w}_t^L$ to consist of $d_{t-a},\ldots,d_1$. With this definition, $(b-a+1)$ defines the maximum number of lags of d used, but `gmm` will proceed with fewer lags if all $(b-a+1)$ lags are not available. If you specify two panel-style instruments, `d` and `e`, say, then $\mathbf{w}_t^L$ will consist of $d_{t-a},\ldots,d_{t-b},e_{t-a},\ldots,e_{t-b}$. $\mathbf{w}_t^D$ is handled analogously.

The $\mathbf{x}_t^L$ vectors are simply $j\times 1$ vectors, where j is the number of regular instruments specified with the `instruments()` option; these vectors include a "1" unless you specify the `noconstant` suboption.

Looking carefully at (A3), you will notice that for dynamic panel-data models, moment conditions corresponding to the instruments $\mathbf{x}_{pt}^L$ take the form

$$E\left[\sum_{t=1}^{t=T}\mathbf{x}_{pt}^L u_{pt}^L(\beta)\right]=\mathbf{0}$$

and likewise for $\mathbf{x}_{pt}^D$. Instead of having separate moment conditions for each time period, there is one moment condition equal to the average of individual periods' moments. See Arellano and Bond (1991, 280). To include separate moment conditions for each time period, instead of specifying, say,

```
instruments(1: x)
```

you could instead first generate a variable called `one` equal to unity for all observations and specify

```
xtinstruments(1: x one)
```

(Creating the variable `one` is necessary because a constant is not automatically included in variable lists specified in `xtinstruments()`.)

Unbalanced panels are essentially handled by including zeros rows and columns of $\mathbf{Z}_p$ and $\mathbf{u}_p(\beta)$ corresponding to missing time periods. However, the numbers of instruments and moment conditions reported by `gmm` do not reflect this trickery and instead reflect the numbers of instruments and moment conditions that are not manipulated in this way. Moreover, `gmm` includes code to work through these situations efficiently without actually having to fill in zeros.

When you specify `winitial(xt ...)`, the one-step unadjusted VCE is computed as

$$\mathrm{Var}(\widehat{\beta})=\widehat{\sigma}_1^2\mathbf{\Lambda}_H$$

where $\mathbf{\Lambda}_H$ was defined previously,

$$\widehat{\sigma}_1^2=(N-k)^{-1}\sum_{p=1}^{p=P}\mathbf{u}_p^D(\widehat{\beta})$$

and $\mathbf{u}_p^D(\widehat{\beta})=[u_{p2}^D(\widehat{\beta}),\ldots,u_{pT}^D(\widehat{\beta})]$. Here we use $(N-k)^{-1}$ instead of N^{-1} to match `xtdpd`.

Title

gmm postestimation — Postestimation tools for gmm

Description

The following postestimation command is of special interest after gmm:

Command	Description
estat overid	perform test of overidentifying restrictions

For information about this command, see below.

The following standard postestimation commands are also available:

Command	Description
estat	VCE
estimates	cataloging estimation results
lincom	point estimates, standard errors, testing, and inference for linear combinations of coefficients
nlcom	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
predict	residuals
predictnl	point estimates, standard errors, testing, and inference for generalized predictions
test	Wald tests of simple and composite linear hypotheses
testnl	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation command

`estat overid` reports Hansen's J statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. If the model is correctly specified in the sense that $E\{\mathbf{z}_i u_i(\boldsymbol{\beta})\} = \mathbf{0}$, then the sample analog to that condition should hold at the estimated value of $\boldsymbol{\beta}$. Hansen's J statistic is valid only if the weight matrix is optimal, meaning that it equals the inverse of the covariance matrix of the moment conditions. Therefore, `estat overid` only reports Hansen's J statistic after two-step or iterated estimation, or if you specified `winitial(`*matname*`)` when calling gmm. In the latter case, it is your responsibility to determine the validity of the J statistic.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`, equation(#`*eqno* | *eqname*`)`]

`predict` [*type*] { *stub*`*` | *newvar*$_1$ ... *newvar*$_q$ } [*if*] [*in*]

Residuals are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

You specify one new variable and (optionally) `equation()`, or you specify *stub*`*` or q new variables, where q is the number of moment equations.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Option for predict

Main

`equation(#`*eqno* | *eqname*`)` specifies the equation for which residuals are desired. Specifying `equation(#1)` indicates that the calculation is to be made for the first moment equation. Specifying `equation(demand)` would indicate that the calculation is to be made for the moment equation named `demand`, assuming there is an equation named `demand` in the model.

If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

For more information on using `predict` after multiple-equation estimation commands, see [R] **predict**.

Syntax for estat overid

```
estat overid
```

Statistics > Postestimation > Reports and statistics

Remarks

As we noted in *Introduction* of [R] **gmm**, underlying generalized method of moments (GMM) estimators is a set of l moment conditions, $E\{\mathbf{z}_i u_i(\beta)\} = \mathbf{0}$. When l is greater than the number of parameters, k, any size-k subset of the moment conditions would yield a consistent parameter estimate. We remarked that the parameter estimates we would obtain would in general depend on which k moment conditions we used. However, if all our moment conditions are indeed valid, then the parameter estimates should not differ too much regardless of which k moment conditions we used to estimate the parameters. The test of overidentifying restrictions is a model specification test based on this observation. The test of overidentifying restrictions requires that the number of moment conditions be greater than the number of parameters in the model.

Recall that the GMM criterion function is

$$Q = \left\{ \frac{1}{N} \sum_i \mathbf{z}_i u_i(\beta) \right\}' \mathbf{W} \left\{ \frac{1}{N} \sum_i \mathbf{z}_i u_i(\beta) \right\}$$

The test of overidentifying restrictions is remarkably simple. If $\mathbf{W}$ is an optimal weight matrix, under the null hypothesis $H_0\colon E\{\mathbf{z}_i u_i(\beta)\} = \mathbf{0}$, the test statistic $J = N \times Q \sim \chi^2(l-k)$. A large test statistic casts doubt on the null hypothesis.

For the test to be valid, $\mathbf{W}$ must be optimal, meaning that $\mathbf{W}$ must be the inverse of the covariance matrix of the moment conditions:

$$\mathbf{W}^{-1} = E\{\mathbf{z}_i u_i(\beta) u_i'(\beta) \mathbf{z}_i'\}$$

Therefore, `estat overid` works only after the two-step and iterated estimators, or if you supplied your own initial weight matrix by using the `winitial(`*matname*`)` option to `gmm` and used the one-step estimator.

Often the overidentifying restrictions test is interpreted as a test of the validity of the instruments **z**. However, other forms of model misspecification can sometimes lead to a significant test statistic. See Hall (2005, sec. 5.1) for a discussion of the overidentifying restrictions test and its behavior in correctly and misspecified models.

▷ Example 1

In example 6 of [R] **gmm**, we fit an exponential regression model of the number of doctor visits based on the person's gender, income, possession of private health insurance, and presence of a chronic disease. We argued that the variable `income` may be endogenous; we used the person's age and race as additional instrumental variables. Here we refit the model and test the specification of the model. We type

```
. use http://www.stata-press.com/data/r12/docvisits
. gmm (docvis - exp({xb:private chronic female income} + {b0})),
> instruments(private chronic female age black hispanic)
(output omitted)
. estat overid
  Test of overidentifying restriction:
  Hansen's J chi2(2) = 9.52598 (p = 0.0085)
```

The J statistic is significant even at the 1% significance level, so we conclude that our model is misspecified. One possibility is that age and race directly affect the number of doctor visits, so we are not justified in excluding them from the model.

A simple technique to explore whether any of the instruments is invalid is to examine the statistics

$$r_j = \mathbf{W}_{jj}^{1/2} \left\{ \frac{1}{N} \sum_{i=1}^{N} z_{ij} u_i(\widehat{\beta}) \right\}$$

for $j = 1, \ldots, k$, where $\mathbf{W}_{jj}$ denotes the jth diagonal element of $\mathbf{W}$, $u_i(\widehat{\beta})$ denotes the sample residuals, and k is the number of instruments. If all the instruments are valid, then the scaled sample moments should at least be on the same order of magnitude. If one (or more) instrument's r_j is large in absolute value relative to the others, then that could be an indication that instrument is not valid.

In Stata, we type

```
. predict double r if e(sample)   // obtain residual from the model
. matrix W = e(W)                 // retrieve weight matrix
. local i 1
. // loop over each instrument and compute r_j
. foreach var of varlist private chronic female age black hispanic {
  2.         generate double r`var' = r*`var'*sqrt(W[`i', `i'])
  3.         local `++i'
  4. }
```

```
. summarize r*
```

Variable	Obs	Mean	Std. Dev.	Min	Max
r	4412	.0344373	8.26176	-151.1847	113.059
rprivate	4412	.007988	3.824118	-72.66254	54.33852
rchronic	4412	.0026947	2.0707	-43.7311	32.703
rfemale	4412	.0028168	1.566397	-12.7388	24.43621
rage	4412	.0360978	4.752986	-89.74112	55.58143
rblack	4412	-.0379317	1.062027	-24.39747	27.34512
rhispanic	4412	-.017435	1.08567	-5.509386	31.53512

We notice that the r_j statistics for `age`, `black`, and `hispanic` are larger than those for the other instruments in our model, supporting our suspicion that age and race may have a direct impact on the number of doctor visits.

◁

Saved results

`estat overid` saves the following in `r()`:

Scalars

`r(J)`	Hansen's J statistic
`r(J_df)`	J statistic degrees of freedom
`r(J_p)`	J statistic p-value

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

grmeanby — Graph means and medians by categorical variables

Syntax

`grmeanby` *varlist* [*if*] [*in*] [*weight*] , `summarize(`*varname*`)` [*options*]

options	Description
Main	
* `summarize(`*varname*`)`	graph mean (or median) of *varname*
`median`	graph medians; default is to graph means
Plot	
cline_options	change the look of the lines
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

*`summarize(`*varname*`)` is required.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Graph means/medians by groups

Description

`grmeanby` graphs the (optionally weighted) means or medians of *varname* according to the values of the variables in *varlist*. The variables in *varlist* may be string or numeric and, if numeric, may be labeled.

Options

Main

`summarize(`*varname*`)` is required; it specifies the name of the variable whose mean or median is to be graphed.

`median` specifies that the graph is to be of medians, not means.

Plot

cline_options affect the rendition of the lines through the markers, including their color, pattern, and width; see [G-3] ***cline_options***.

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

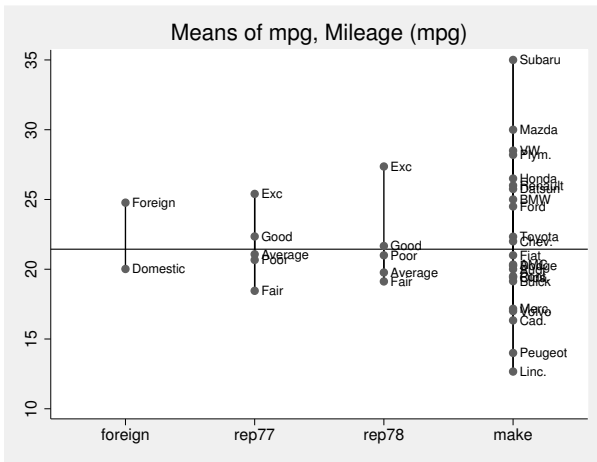
Remarks

The idea of graphing means of categorical variables was shown in Chambers and Hastie (1992, 3). Because this was shown in the context of an S function for making such graphs, it doubtless has roots going back further than that. `grmeanby` is, in any case, another implementation of what we will assume is their idea.

▷ Example 1

Using a variation of our auto dataset, we graph the mean of `mpg` by `foreign`, `rep77`, `rep78`, and `make`:

```
. use http://www.stata-press.com/data/r12/auto1
(Automobile Models)
. grmeanby foreign rep77 rep78 make, sum(mpg)
```



If we had wanted a graph of medians rather than means, we could have typed

```
. grmeanby foreign rep77 rep78 make, sum(mpg) median
```

◁

Methods and formulas

`grmeanby` is implemented as an ado-file.

Title

hausman — Hausman specification test

Syntax

`hausman` *name-consistent* [*name-efficient*] [, *options*]

options	Description
Main	
`constant`	include estimated intercepts in comparison; default is to exclude
`alleqs`	use all equations to perform test; default is first equation only
`skipeqs(`*eqlist*`)`	skip specified equations when performing test
`equations(`*matchlist*`)`	associate/compare the specified (by number) pairs of equations
`force`	force performance of test, even though assumptions are not met
`df(#)`	use # degrees of freedom
`sigmamore`	base both (co)variance matrices on disturbance variance estimate from efficient estimator
`sigmaless`	base both (co)variance matrices on disturbance variance estimate from consistent estimator
Advanced	
`tconsistent(`*string*`)`	consistent estimator column header
`tefficient(`*string*`)`	efficient estimator column header

where *name-consistent* and *name-efficient* are names under which estimation results were saved via `estimates store`; see [R] **estimates store**.

A period (`.`) may be used to refer to the last estimation results, even if these were not already stored.

Not specifying *name-efficient* is equivalent to specifying the last estimation results as ".".

Menu

Statistics > Postestimation > Tests > Hausman specification test

Description

`hausman` performs Hausman's (1978) specification test.

Options

Main

`constant` specifies that the estimated intercept(s) be included in the model comparison; by default, they are excluded. The default behavior is appropriate for models in which the constant does not have a common interpretation across the two models.

`alleqs` specifies that all the equations in the models be used to perform the Hausman test; by default, only the first equation is used.

`skipeqs(`*eqlist*`)` specifies in *eqlist* the names of equations to be excluded from the test. Equation numbers are not allowed in this context, because the equation names, along with the variable names, are used to identify common coefficients.

`equations(`*matchlist*`)` specifies, by number, the pairs of equations that are to be compared.

The *matchlist* in `equations()` should follow the syntax

$$\#_c{:}\#_e\ \left[,\#_c{:}\#_e\left[,\ldots\right]\right]$$

where $\#_c$ ($\#_e$) is an equation number of the always-consistent (efficient under H_0) estimator. For instance, `equations(1:1)`, `equations(1:1, 2:2)`, or `equations(1:2)`.

If `equations()` is not specified, then equations are matched on equation names.

`equations()` handles the situation in which one estimator uses equation names and the other does not. For instance, `equations(1:2)` means that equation 1 of the always-consistent estimator is to be tested against equation 2 of the efficient estimator. `equations(1:1, 2:2)` means that equation 1 is to be tested against equation 1 and that equation 2 is to be tested against equation 2. If `equations()` is specified, the `alleqs` and `skipeqs` options are ignored.

`force` specifies that the Hausman test be performed, even though the assumptions of the Hausman test seem not to be met, for example, because the estimators were `pweighted` or the data were clustered.

`df(#)` specifies the degrees of freedom for the Hausman test. The default is the matrix rank of the variance of the difference between the coefficients of the two estimators.

`sigmamore` and `sigmaless` specify that the two covariance matrices used in the test be based on a common estimate of disturbance variance (σ^2).

`sigmamore` specifies that the covariance matrices be based on the estimated disturbance variance from the efficient estimator. This option provides a proper estimate of the contrast variance for so-called tests of exogeneity and overidentification in instrumental-variables regression.

`sigmaless` specifies that the covariance matrices be based on the estimated disturbance variance from the consistent estimator.

These options can be specified only when both estimators save `e(sigma)` or `e(rmse)`, or with the `xtreg` command. `e(sigma_e)` is saved after the `xtreg` command with the option `fe` or `mle` option. `e(rmse)` is saved after the `xtreg` command with the `re` option.

`sigmamore` or `sigmaless` are recommended when comparing fixed-effects and random-effects linear regression because they are much less likely to produce a non–positive-definite-differenced covariance matrix (although the tests are asymptotically equivalent whether or not one of the options is specified).

Advanced

`tconsistent(`*string*`)` and `tefficient(`*string*`)` are formatting options. They allow you to specify the headers of the columns of coefficients that default to the names of the models. These options will be of interest primarily to programmers.

Remarks

`hausman` is a general implementation of Hausman's (1978) specification test, which compares an estimator $\widehat{\theta}_1$ that is known to be consistent with an estimator $\widehat{\theta}_2$ that is efficient under the assumption being tested. The null hypothesis is that the estimator $\widehat{\theta}_2$ is indeed an efficient (and consistent) estimator of the true parameters. If this is the case, there should be no systematic difference between the two estimators. If there exists a systematic difference in the estimates, you have reason to doubt the assumptions on which the efficient estimator is based.

The assumption of efficiency is violated if the estimator is `pweighted` or the data are clustered, so `hausman` cannot be used. The test can be forced by specifying the `force` option with `hausman`. For an alternative to using `hausman` in these cases, see [R] **suest**.

To use `hausman`, you

```
. (compute the always-consistent estimator)
. estimates store name-consistent
. (compute the estimator that is efficient under H_0)
. hausman name-consistent .
```

Alternatively, you can turn this around:

```
. (compute the estimator that is efficient under H_0)
. estimates store name-efficient
. (fit the less-efficient model)
. (compute the always-consistent estimator)
. hausman . name-efficient
```

You can, of course, also compute and store both the always-consistent and efficient-under-H_0 estimators and perform the Hausman test with

```
. hausman name-consistent name-efficient
```

▷ Example 1

We are studying the factors that affect the wages of young women in the United States between 1970 and 1988, and we have a panel-data sample of individual women over that time span.

We assume that this model is consistent for the true parameters and save the results by using `estimates store` under a name, `fixed`:

```
. estimates store fixed
```

Now we fit a random-effects model as a fully efficient specification of the individual effects under the assumption that they are random and follow a normal distribution. We then compare these estimates with the previously saved results by using the `hausman` command.

```

Under the current specification, our initial hypothesis that the individual-level effects are adequately modeled by a random-effects model is resoundingly rejected. This result is based on the rest of our model specification, and random effects might be appropriate for some alternate model of wages.

◁

Jerry Allen Hausman was born in West Virginia in 1946. He studied economics at Brown and Oxford, has been at MIT since 1972, and has made many outstanding contributions to econometrics and applied microeconometrics.

▷ Example 2

A stringent assumption of multinomial and conditional logit models is that outcome categories for the model have the property of independence of irrelevant alternatives (IIA). Stated simply, this assumption requires that the inclusion or exclusion of categories does not affect the relative risks associated with the regressors in the remaining categories.

One classic example of a situation in which this assumption would be violated involves the choice of transportation mode; see McFadden (1974). For simplicity, postulate a transportation model with the four possible outcomes: rides a train to work, takes a bus to work, drives the Ford to work, and drives the Chevrolet to work. Clearly, "drives the Ford" is a closer substitute to "drives the Chevrolet" than it is to "rides a train" (at least for most people). This means that excluding "drives the Ford" from the model could be expected to affect the relative risks of the remaining options and that the model would not obey the IIA assumption.

Using the data presented in [R] **mlogit**, we will use a simplified model to test for IIA. The choice of insurance type among indemnity, prepaid, and uninsured is modeled as a function of age and gender. The indemnity category is allowed to be the base category, and the model including all three outcomes is fit. The results are then stored under the name `allcats`.

Under the IIA assumption, we would expect no systematic change in the coefficients if we excluded one of the outcomes from the model. (For an extensive discussion, see Hausman and McFadden [1984].) We reestimate the parameters, excluding the uninsured outcome, and perform a Hausman test against the fully efficient full model.

              (V_b-V_B is not positive definite)
```

The syntax of the `if` condition on the `mlogit` command simply identified the `"Uninsured"` category with the `insure` value label; see [U] **12.6.3 Value labels**. On examining the output from `hausman`, we see that there is no evidence that the IIA assumption has been violated.

Because the Hausman test is a standardized comparison of model coefficients, using it with `mlogit` requires that the base outcome be the same in both competing models. In particular, if the most-frequent category (the default base outcome) is being removed to test for IIA, you must use the `baseoutcome()` option in `mlogit` to manually set the base outcome to something else. Or you can use the `equation()` option of the `hausman` command to align the equations of the two models.

Having the missing values for the square root of the diagonal of the covariance matrix of the differences is not comforting, but it is also not surprising. This covariance matrix is guaranteed to be positive definite only asymptotically (it is a consequence of the assumption that one of the estimators is efficient), and assurances are not made about the diagonal elements. Negative values along the diagonal are possible, and the fourth column of the table is provided mainly for descriptive use.

We can also perform the Hausman IIA test against the remaining alternative in the model:

```

Here the χ^2 statistic is actually negative. We might interpret this result as strong evidence that we cannot reject the null hypothesis. Such a result is not an unusual outcome for the Hausman test, particularly when the sample is relatively small—there are only 45 uninsured individuals in this dataset.

Are we surprised by the results of the Hausman test in this example? Not really. Judging from the z statistics on the original multinomial logit model, we were struggling to identify any structure in the data with the current specification. Even when we were willing to assume IIA and computed the efficient estimator under this assumption, few of the effects could be identified as statistically different from those on the base category. Trying to base a Hausman test on a contrast (difference) between two poor estimates is just asking too much of the existing data.

◁

In example 2, we encountered a case in which the Hausman was not well defined. Unfortunately, in our experience this happens fairly often. Stata provides an alternative to the Hausman test that overcomes this problem through an alternative estimator of the variance of the difference between the two estimators. This other estimator is guaranteed to be positive semidefinite. This alternative estimator also allows a widening of the scope of problems to which Hausman-type tests can be applied by relaxing the assumption that one of the estimators is efficient. For instance, you can perform Hausman-type tests to clustered observations and survey estimators. See [R] **suest** for details.

Saved results

`hausman` saves the following in `r()`:

Scalars

`r(chi2)`	χ^2
`r(df)`	degrees of freedom for the statistic
`r(p)`	p-value for the χ^2
`r(rank)`	rank of `(V_b-V_B)^(-1)`

Methods and formulas

`hausman` is implemented as an ado-file.

The Hausman statistic is distributed as χ^2 and is computed as

$$H = (\beta_c - \beta_e)'(V_c - V_e)^{-1}(\beta_c - \beta_e)$$

where

β_c	is the coefficient vector from the consistent estimator
β_e	is the coefficient vector from the efficient estimator
V_c	is the covariance matrix of the consistent estimator
V_e	is the covariance matrix of the efficient estimator

When the difference in the variance matrices is not positive definite, a Moore–Penrose generalized inverse is used. As noted in Gourieroux and Monfort (1995, 125–128), the choice of generalized inverse is not important asymptotically.

The number of degrees of freedom for the statistic is the rank of the difference in the variance matrices. When the difference is positive definite, this is the number of common coefficients in the models being compared.

Acknowledgment

Portions of `hausman` are based on an early implementation by Jeroen Weesie, Utrecht University, The Netherlands.

Title

heckman — Heckman selection model

Syntax

Basic syntax

```
heckman depvar [indepvars], select(varlist_s) [twostep]
```

or

```
heckman depvar [indepvars], select(depvar_s = varlist_s) [twostep]
```

Full syntax for maximum likelihood estimates only

```
heckman depvar [indepvars] [if] [in] [weight],
    select([depvar_s =] varlist_s [, offset(varname) noconstant])
    [heckman_ml_options]
```

Full syntax for Heckman's two-step consistent estimates only

```
heckman depvar [indepvars] [if] [in], twostep
    select([depvar_s =] varlist_s [, noconstant]) [heckman_ts_options]
```

heckman_ml_options	Description
Model	
* `select()`	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
`noconstant`	suppress constant term
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`first`	report first-step probit estimates
`noskip`	perform likelihood-ratio test
`nshazard(`*newvar*`)`	generate nonselection hazard variable
`mills(`*newvar*`)`	synonym for `nshazard()`
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells

Maximization

maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

*select() is required.
The full specification is select([*depvar*$_s$ =] *varlist*$_s$ [, offset(*varname*) noconstant]) .

heckman_ts_options	Description
Model	
*select()	specify selection equation: dependent and independent variables; whether to have constant term
*twostep	produce two-step consistent estimate
noconstant	suppress constant term
rhosigma	truncate ρ to $[-1, 1]$ with consistent σ
rhotrunc	truncate ρ to $[-1, 1]$
rholimited	truncate ρ in limited cases
rhoforce	do not truncate ρ
SE	
vce(*vcetype*)	*vcetype* may be conventional, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
first	report first-step probit estimates
nshazard(*newvar*)	generate nonselection hazard variable
mills(*newvar*)	synonym for nshazard()
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
coeflegend	display legend instead of statistics

*select() and twostep are required.
The full specification is select([*depvar*$_s$ =] *varlist*$_s$ [, noconstant])

indepvars and *varlist*$_s$ may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar, *indepvars*, *varlist*$_s$, and *depvar*$_s$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
aweights are not allowed with the jackknife prefix; see [R] **jackknife**.
twostep, vce(), first, noskip, and weights are not allowed with the svy prefix; see [SVY] **svy**.
pweights, aweights, fweights, and iweights are allowed with maximum likelihood estimation; see [U] **11.1.6 weight**. No weights are allowed if twostep is specified.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

heckman for maximum likelihood estimates

Statistics > Sample-selection models > Heckman selection model (ML)

heckman for two-step consistent estimates

Statistics > Sample-selection models > Heckman selection model (two-step)

Description

`heckman` fits regression models with selection by using either Heckman's two-step consistent estimator or full maximum likelihood.

Options for Heckman selection model (ML)

Model

`select(...)` specifies the variables and options for the selection equation. It is an integral part of specifying a Heckman model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If $depvar_s$ is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If $depvar_s$ is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

`noconstant`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`noskip` specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test that all the parameters in the regression equation are zero (except the constant). For many models, this option can substantially increase estimation time.

`nshazard(`*newvar*`)` and `mills(`*newvar*`)` are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills' ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

`nocnsreport`; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default *vcetype* to vce(opg).

The following option is available with heckman but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Options for Heckman selection model (two-step)

Model

select(...) specifies the variables and options for the selection equation. It is an integral part of specifying a Heckman model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If $depvar_s$ is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If $depvar_s$ is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

twostep specifies that Heckman's (1979) two-step efficient estimates of the parameters, standard errors, and covariance matrix be produced.

noconstant; see [R] **estimation options**.

rhosigma, rhotrunc, rholimited, and rhoforce are rarely used options to specify how the two-step estimator (option twostep) handles unusual cases in which the two-step estimate of ρ is outside the admissible range for a correlation, $[-1, 1]$. When $\text{abs}(\rho) > 1$, the two-step estimate of the coefficient variance–covariance matrix may not be positive definite and thus may be unusable for testing. The default is rhosigma.

rhosigma specifies that ρ be truncated, as with the rhotrunc option, and that the estimate of σ be made consistent with $\widehat{\rho}$, the truncated estimate of ρ. So, $\widehat{\sigma} = \boldsymbol{\beta}_m\widehat{\rho}$; see *Methods and formulas* for the definition of $\boldsymbol{\beta}_m$. Both the truncated ρ and the new estimate of $\widehat{\sigma}$ are used in all computations to estimate the two-step covariance matrix.

rhotrunc specifies that ρ be truncated to lie in the range $[-1, 1]$. If the two-step estimate is less than -1, ρ is set to -1; if the two-step estimate is greater than 1, ρ is set to 1. This truncated value of ρ is used in all computations to estimate the two-step covariance matrix.

rholimited specifies that ρ be truncated only in computing the diagonal matrix $\mathbf{D}$ as it enters $\mathbf{V}_{\text{twostep}}$ and $\mathbf{Q}$; see *Methods and formulas*. In all other computations, the untruncated estimate of ρ is used.

rhoforce specifies that the two-step estimate of ρ be retained, even if it is outside the admissible range for a correlation. This option may, in rare cases, lead to a non–positive-definite covariance matrix.

These options have no effect when estimation is by maximum likelihood, the default. They also have no effect when the two-step estimate of ρ is in the range $[-1, 1]$.

SE

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(conventional)`, the default, uses the two-step variance estimator derived by Heckman.

Reporting

`level(#)`; see [R] **estimation options**.

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`nshazard(`*newvar*`)` and `mills(`*newvar*`)` are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills' ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `heckman` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

The Heckman selection model (Gronau 1974; Lewis 1974; Heckman 1976) assumes that there exists an underlying regression relationship,

$$y_j = \mathbf{x}_j\boldsymbol{\beta} + u_{1j} \qquad \textit{regression equation}$$

The dependent variable, however, is not always observed. Rather, the dependent variable for observation j is observed if

$$\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0 \qquad \textit{selection equation}$$

where

$$u_1 \sim N(0, \sigma)$$
$$u_2 \sim N(0, 1)$$
$$\text{corr}(u_1, u_2) = \rho$$

When $\rho \neq 0$, standard regression techniques applied to the first equation yield biased results. `heckman` provides consistent, asymptotically efficient estimates for all the parameters in such models.

In one classic example, the first equation describes the wages of women. Women choose whether to work, and thus, from our point of view as researchers, whether we observe their wages in our data. If women made this decision randomly, we could ignore that not all wages are observed and use ordinary regression to fit a wage model. Such an assumption of random participation, however, is unlikely to be true; women who would have low wages may be unlikely to choose to work, and thus the sample of observed wages is biased upward. In the jargon of economics, women choose not to work when their personal reservation wage is greater than the wage offered by employers. Thus

women who choose not to work might have even higher offer wages than those who do work—they may have high offer wages, but they have even higher reservation wages. We could tell a story that competency is related to wages, but competency is rewarded more at home than in the labor force.

In any case, in this problem—which is the paradigm for most such problems—a solution can be found if there are some variables that strongly affect the chances for observation (the reservation wage) but not the outcome under study (the offer wage). Such a variable might be the number of children in the home. (Theoretically, we do not need such identifying variables, but without them, we depend on functional form to identify the model. It would be difficult for anyone to take such results seriously because the functional-form assumptions have no firm basis in theory.)

▷ Example 1

In the syntax for `heckman`, *depvar* and *indepvars* are the dependent variable and regressors for the underlying regression model to be fit ($\mathbf{y} = \mathbf{X}\beta$), and $varlist_s$ are the variables ($\mathbf{Z}$) thought to determine whether *depvar* is observed or unobserved (selected or not selected). In our female wage example, the number of children at home would be included in the second list. By default, `heckman` assumes that missing values (see [U] **12.2.1 Missing values**) of *depvar* imply that the dependent variable is unobserved (not selected). With some datasets, it is more convenient to specify a binary variable ($depvar_s$) that identifies the observations for which the dependent is observed/selected ($depvar_s \neq 0$) or not observed ($depvar_s = 0$); `heckman` will accommodate either type of data.

We have a (fictional) dataset on 2,000 women, 1,343 of whom work:

```
. use http://www.stata-press.com/data/r12/womenwk
. summarize age educ married children wage
```

Variable	Obs	Mean	Std. Dev.	Min	Max
age	2000	36.208	8.28656	20	59
education	2000	13.084	3.045912	10	20
married	2000	.6705	.4701492	0	1
children	2000	1.6445	1.398963	0	5
wage	1343	23.69217	6.305374	5.88497	45.80979

We will assume that the hourly wage is a function of education and age, whereas the likelihood of working (the likelihood of the wage being observed) is a function of marital status, the number of children at home, and (implicitly) the wage (via the inclusion of age and education, which we think determine the wage):

```
. heckman wage educ age, select(married children educ age)
Iteration 0:   log likelihood = -5178.7009
Iteration 1:   log likelihood = -5178.3049
Iteration 2:   log likelihood = -5178.3045

```

`heckman` assumes that `wage` is the dependent variable and that the first variable list (`educ` and `age`) are the determinants of `wage`. The variables specified in the `select()` option (`married`, `children`, `educ`, and `age`) are assumed to determine whether the dependent variable is observed (the selection equation). Thus we fit the model

$$\texttt{wage} = \beta_0 + \beta_1\texttt{educ} + \beta_2\texttt{age} + u_1$$

and we assumed that `wage` is observed if

$$\gamma_0 + \gamma_1\texttt{married} + \gamma_2\texttt{children} + \gamma_3\texttt{educ} + \gamma_4\texttt{age} + u_2 > 0$$

where u_1 and u_2 have correlation ρ.

The reported results for the wage equation are interpreted exactly as though we observed wage data for all women in the sample; the coefficients on age and education level represent the estimated marginal effects of the regressors in the underlying regression equation. The results for the two ancillary parameters require some explanation. `heckman` does not directly estimate ρ; to constrain ρ within its valid limits, and for numerical stability during optimization, it estimates the inverse hyperbolic tangent of ρ:

$$\operatorname{atanh}\rho = \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right)$$

This estimate is reported as /athrho. In the bottom panel of the output, heckman undoes this transformation for you: the estimated value of ρ is 0.7035061. The standard error for ρ is computed using the delta method, and its confidence intervals are the transformed intervals of /athrho.

Similarly, σ, the standard error of the residual in the wage equation, is not directly estimated; for numerical stability, heckman instead estimates $\ln\sigma$. The untransformed sigma is reported at the end of the output: 6.004797.

Finally, some researchers—especially economists—are used to the selectivity effect summarized not by ρ but by $\lambda = \rho\sigma$. heckman reports this, too, along with an estimate of the standard error and confidence interval.

◁

❑ Technical note

If each of the equations in the model had contained many regressors, the heckman command could have become long. An alternate way of specifying our wage model would be to use Stata's global macros. The following lines are an equivalent way of specifying our model:

```
. global wageeq "wage educ age"
. global seleq "married children educ age"
. heckman $wageeq, select($seleq)
```
(*output omitted*)

❑

❑ Technical note

The reported model χ^2 test is a Wald test that all coefficients in the regression model (except the constant) are 0. heckman is an estimation command, so you can use test, testnl, or lrtest to perform tests against whatever nested alternate model you choose; see [R] **test**, [R] **testnl**, and [R] **lrtest**.

The estimation of ρ and σ in the forms $\operatorname{atanh}\rho$ and $\ln\sigma$ extends the range of these parameters to infinity in both directions, thus avoiding boundary problems during the maximization. Tests of ρ must be made in the transformed units. However, because $\operatorname{atanh}(0) = 0$, the reported test for $\operatorname{atanh}\rho = 0$ is equivalent to the test for $\rho = 0$.

The likelihood-ratio test reported at the bottom of the output is an equivalent test for $\rho = 0$ and is computationally the comparison of the joint likelihood of an independent probit model for the selection equation and a regression model on the observed wage data against the Heckman model likelihood. Because $\chi^2 = 61.20$, this clearly justifies the Heckman selection equation with these data.

❑

▷ Example 2

heckman supports the Huber/White/sandwich estimator of variance under the vce(robust) and vce(cluster *clustvar*) options or when pweights are used for population-weighted data; see [U] **20.20 Obtaining robust variance estimates**. We can obtain robust standard errors for our wage model by specifying clustering on county of residence (the county variable).

```
. heckman wage educ age, select(married children educ age) vce(cluster county)
Iteration 0:   log pseudolikelihood = -5178.7009
Iteration 1:   log pseudolikelihood = -5178.3049
Iteration 2:   log pseudolikelihood = -5178.3045
Heckman selection model                         Number of obs      =      2000
(regression model with sample selection)        Censored obs       =       657
                                                Uncensored obs     =      1343
                                                Wald chi2(1)       =         .
Log pseudolikelihood = -5178.304                Prob > chi2        =         .
                                (Std. Err. adjusted for 10 clusters in county)

Wald test of indep. eqns. (rho = 0): chi2(1) =    38.81   Prob > chi2 = 0.0000
```

The robust standard errors tend to be a bit larger, but we notice no systematic differences. This finding is not surprising because the data were not constructed to have any county-specific correlations or any other characteristics that would deviate from the assumptions of the Heckman model.

◁

▷ Example 3

Stata also produces Heckman's (1979) two-step efficient estimator of the model with the `twostep` option. Maximum likelihood estimation of the parameters can be time consuming with large datasets, and the two-step estimates may provide a good alternative in such cases. Continuing with the women's wage model, we can obtain the two-step estimates with Heckman's consistent covariance estimates by typing

```
. heckman wage educ age, select(married children educ age) twostep
Heckman selection model -- two-step estimates   Number of obs      =      2000
(regression model with sample selection)        Censored obs       =       657
                                                Uncensored obs     =      1343
                                                Wald chi2(2)       =    442.54
                                                Prob > chi2        =    0.0000
```

❑ Technical note

The Heckman selection model depends strongly on the model being correct, much more so than ordinary regression. Running a separate probit or logit for sample inclusion followed by a regression, referred to in the literature as the two-part model (Manning, Duan, and Rogers 1987)—not to be confused with Heckman's two-step procedure—is an especially attractive alternative if the regression part of the model arose because of taking a logarithm of zero values. When the goal is to analyze an underlying regression model or to predict the value of the dependent variable that would be observed in the absence of selection, however, the Heckman model is more appropriate. When the goal is to predict an actual response, the two-part model is usually the better choice.

The Heckman selection model can be unstable when the model is not properly specified or if a specific dataset simply does not support the model's assumptions. For example, let's examine the solution to another simulated problem.

```

The model has converged to a value of ρ that is 1.0—within machine-rounding tolerances. Given the form of the likelihood for the Heckman selection model, this implies a division by zero, and it is surprising that the model solution turns out as well as it does. Reparameterizing ρ has allowed the estimation to converge, but we clearly have problems with the estimates. Moreover, if this had occurred in a large dataset, waiting for convergence might take considerable time.

This dataset was not intentionally developed to cause problems. It is actually generated by a "Heckman process" and when generated starting from different random values can be easily estimated. The luck of the draw here merely led to data that, despite the source, did not support the assumptions of the Heckman model.

The two-step model is generally more stable when the data are problematic. It even tolerates estimates of ρ less than -1 and greater than 1. For these reasons, the two-step model may be preferred when exploring a large dataset. Still, if the maximum likelihood estimates cannot converge, or converge to a value of ρ that is at the boundary of acceptable values, there is scant support for fitting a Heckman selection model on the data. Heckman (1979) discusses the implications of ρ being exactly 1 or 0, together with the implications of other possible covariance relationships among the model's determinants.

❑

James Joseph Heckman was born in Chicago in 1944 and studied mathematics at Colorado College and economics at Princeton. He has taught economics at Columbia and (since 1973) at the University of Chicago. He has worked on developing a scientific basis for economic policy evaluation, with emphasis on models of individuals or disaggregated groups and the problems and possibilities created by heterogeneity, diversity, and unobserved counterfactual states. In 2000, he shared the Nobel Prize in Economics with Daniel L. McFadden.

Saved results

`heckman` (maximum likelihood) saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(N_cens)`	number of censored observations
`e(k)`	number of parameters
`e(k_eq)`	number of equations in `e(b)`
`e(k_eq_model)`	number of equations in overall model test
`e(k_aux)`	number of auxiliary parameters
`e(k_dv)`	number of dependent variables
`e(df_m)`	model degrees of freedom
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(lambda)`	λ
`e(selambda)`	standard error of λ
`e(sigma)`	sigma
`e(chi2)`	χ^2
`e(chi2_c)`	χ^2 for comparison test
`e(p_c)`	p-value for comparison test
`e(p)`	significance of comparison test
`e(rho)`	ρ
`e(rank)`	rank of `e(V)`
`e(rank0)`	rank of `e(V)` for constant-only model
`e(ic)`	number of iterations
`e(rc)`	return code
`e(converged)`	`1` if converged, `0` otherwise

Macros

e(cmd)	heckman
e(cmdline)	command as typed
e(depvar)	names of dependent variables
e(wtype)	weight type
e(wexp)	weight expression

e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(rhometh)	rhosigma, rhotrunc, rholimited, or rhoforce
e(method)	twostep
e(properties)	b V
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

Methods and formulas

heckman is implemented as an ado-file. Cameron and Trivedi (2010, 556–562) and Greene (2012, 873–880) provide good introductions to the Heckman selection model. Adkins and Hill (2008, 395–400) describe the two-step estimator with an application using Stata. Jones (2007, 35–40) illustrates Heckman estimation with an application to health economics.

Regression estimates using the nonselection hazard (Heckman 1979) provide starting values for maximum likelihood estimation.

The regression equation is

$$y_j = \mathbf{x}_j\boldsymbol{\beta} + u_{1j}$$

The selection equation is

$$\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0$$

where

$$u_1 \sim N(0, \sigma)$$
$$u_2 \sim N(0, 1)$$
$$\text{corr}(u_1, u_2) = \rho$$

The log likelihood for observation j, $\ln L_j = l_j$, is

$$l_j = \begin{cases} w_j \ln\Phi\left\{\dfrac{\mathbf{z}_j\boldsymbol{\gamma} + (y_j - \mathbf{x}_j\boldsymbol{\beta})\rho/\sigma}{\sqrt{1-\rho^2}}\right\} - \dfrac{w_j}{2}\left(\dfrac{y_j - \mathbf{x}_j\boldsymbol{\beta}}{\sigma}\right)^2 - w_j \ln(\sqrt{2\pi}\sigma) & y_j \text{ observed} \\ w_j \ln \Phi(-\mathbf{z}_j\boldsymbol{\gamma}) & y_j \text{ not observed} \end{cases}$$

where $\Phi(\cdot)$ is the standard cumulative normal and w_j is an optional weight for observation j.

In the maximum likelihood estimation, σ and ρ are not directly estimated. Directly estimated are $\ln\sigma$ and atanh ρ:

$$\text{atanh}\,\rho = \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right)$$

The standard error of $\lambda = \rho\sigma$ is approximated through the propagation of error (delta) method; that is,

$$\text{Var}(\lambda) \approx \mathbf{D}\,\text{Var}\{(\text{atanh}\,\rho \;\; \ln\sigma)\}\,\mathbf{D}'$$

where $\mathbf{D}$ is the Jacobian of λ with respect to atanh ρ and $\ln\sigma$.

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of heckman also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

The two-step estimates are computed using Heckman's (1979) procedure.

Probit estimates of the selection equation

$$\Pr(y_j \text{ observed} \mid \mathbf{z}_j) = \Phi(\mathbf{z}_j\boldsymbol{\gamma})$$

are obtained. From these estimates, the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills' ratio, m_j—for each observation j is computed as

$$m_j = \frac{\phi(\mathbf{z}_j\widehat{\boldsymbol{\gamma}})}{\Phi(\mathbf{z}_j\widehat{\boldsymbol{\gamma}})}$$

where ϕ is the normal density. We also define

$$\delta_j = m_j(m_j + \widehat{\boldsymbol{\gamma}}\mathbf{z}_j)$$

Following Heckman, the two-step parameter estimates of $\boldsymbol{\beta}$ are obtained by augmenting the regression equation with the nonselection hazard $\mathbf{m}$. Thus the regressors become $[\,\mathbf{X}\;\mathbf{m}\,]$, and we obtain the additional parameter estimate $\boldsymbol{\beta}_m$ on the variable containing the nonselection hazard.

A consistent estimate of the regression disturbance variance is obtained using the residuals from the augmented regression and the parameter estimate on the nonselection hazard,

$$\widehat{\sigma}^2 = \frac{\mathbf{e}'\mathbf{e} + \boldsymbol{\beta}_m^2 \sum_{j=1}^{N} \delta_j}{N}$$

The two-step estimate of ρ is then

$$\widehat{\rho} = \frac{\boldsymbol{\beta}_m}{\widehat{\sigma}}$$

Heckman derived consistent estimates of the coefficient covariance matrix on the basis of the augmented regression.

Let $\mathbf{W} = [\,\mathbf{X}\ \mathbf{m}\,]$ and $\mathbf{R}$ be a square, diagonal matrix of dimension N, with $(1 - \widehat{\rho}^2\delta_j)$ as the diagonal elements. The conventional VCE is

$$\mathbf{V}_{\text{twostep}} = \widehat{\sigma}^2(\mathbf{W}'\mathbf{W})^{-1}(\mathbf{W}'\mathbf{R}\mathbf{W} + \mathbf{Q})(\mathbf{W}'\mathbf{W})^{-1}$$

where

$$\mathbf{Q} = \widehat{\rho}^2(\mathbf{W}'\mathbf{D}\mathbf{Z})\mathbf{V}_{\mathbf{p}}(\mathbf{Z}'\mathbf{D}\mathbf{W})$$

where $\mathbf{D}$ is the square, diagonal matrix of dimension N with δ_j as the diagonal elements; $\mathbf{Z}$ is the data matrix of selection equation covariates; and $\mathbf{V}_p$ is the variance–covariance estimate from the probit estimation of the selection equation.

Title

heckman postestimation — Postestimation tools for heckman

Description

The following postestimation commands are available after `heckman`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`[1]	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[2]	likelihood-ratio test; not available with two-step estimator
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`[1]	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `estat ic` and `suest` are not appropriate after `heckman, twostep`.

[2] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

After ML or twostep

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

After ML

```
predict [type] { stub* | newvar_reg newvar_sel newvar_athrho newvar_lnsigma }
    [if] [in], scores
```

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the prediction
`stdf`	standard error of the forecast
`xbsel`	linear prediction for selection equation
`stdpsel`	standard error of the linear prediction for selection equation
`pr(`a`,`b`)`	$\Pr(y_j \mid a < y_j < b)$
`e(`a`,`b`)`	$E(y_j \mid a < y_j < b)$
`ystar(`a`,`b`)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$
`ycond`	$E(y_j \mid y_j$ observed$)$
`yexpected`	$E(y_j^*)$, y_j taken to be 0 where unobserved
`nshazard` or `mills`	nonselection hazard (also called the inverse of Mills' ratio)
`psel`	$\Pr(y_j$ observed$)$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where a and b may be numbers or variables; a missing ($a \geq .$) means $-\infty$, and b missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction $\mathbf{x}_j\mathbf{b}$.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

`xbsel` calculates the linear prediction for the selection equation.

`stdpsel` calculates the standard error of the linear prediction for the selection equation.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_1 < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names; `pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b}+u_1 < 30)$; `pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b}+u_1 < ub)$; and `pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_1 < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$; `pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$ and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$; `pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$ and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_1 \mid a < \mathbf{x}_j\mathbf{b} + u_1 < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated.
a and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b}+u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`ycond` calculates the expected value of the dependent variable conditional on the dependent variable being observed, that is, selected; $E(y_j \mid y_j \text{ observed})$.

`yexpected` calculates the expected value of the dependent variable (y_j^*), where that value is taken to be 0 when it is expected to be unobserved; $y_j^* = \Pr(y_j \text{ observed})E(y_j \mid y_j \text{ observed})$.

The assumption of 0 is valid for many cases where nonselection implies nonparticipation (for example, unobserved wage levels, insurance claims from those who are uninsured) but may be inappropriate for some problems (for example, unobserved disease incidence).

`nshazard` and `mills` are synonyms; both calculate the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills' ratio—from the selection equation.

`psel` calculates the probability of selection (or being observed): $\Pr(y_j \text{ observed}) = \Pr(\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0)$.

`nooffset` is relevant when you specify `offset(`*varname*`)` for `heckman`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores`, not available with `twostep`, calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\mathbf{z}_j\boldsymbol{\gamma})$.

The third new variable will contain $\partial \ln L/\partial(\operatorname{atanh}\rho)$.

The fourth new variable will contain $\partial \ln L/\partial(\ln\sigma)$.

Remarks

▷ Example 1

The default statistic produced by `predict` after `heckman` is the expected value of the dependent variable from the underlying distribution of the regression model. In the wage model of [R] **heckman**, this is the expected wage rate among all women, regardless of whether they were observed to participate in the labor force:

```
. use http://www.stata-press.com/data/r12/womenwk
. heckman wage educ age, select(married children educ age) vce(cluster county)
  (output omitted)
. predict heckwage
(option xb assumed; fitted values)
```

It is instructive to compare these predicted wage values from the Heckman model with an ordinary regression model—a model without the selection adjustment:

```
. regress wage educ age
      Source |       SS       df       MS              Number of obs =    1343
-------------+------------------------------           F(  2,  1340) =  227.49
       Model |  13524.0337     2  6762.01687            Prob > F      =  0.0000
    Residual |  39830.8609  1340  29.7245231            R-squared     =  0.2535
-------------+------------------------------           Adj R-squared =  0.2524
       Total |  53354.8946  1342  39.7577456            Root MSE      =   5.452

------------------------------------------------------------------------------
        wage |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   education |   .8965829   .0498061    18.00   0.000     .7988765    .9942893
         age |   .1465739   .0187135     7.83   0.000      .109863    .1832848
       _cons |   6.084875   .8896182     6.84   0.000     4.339679    7.830071
------------------------------------------------------------------------------

. predict regwage
(option xb assumed; fitted values)
. summarize heckwage regwage
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
    heckwage |      2000    21.15532     3.83965    14.6479   32.85949
     regwage |      2000    23.12291    3.241911   17.98218   32.66439
```

Since this dataset was concocted, we know the true coefficients of the wage regression equation to be 1, 0.2, and 1, respectively. We can compute the true mean wage for our sample.

```
. generate truewage = 1 + .2*age + 1*educ
. summarize truewage
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
    truewage |      2000     21.3256    3.797904         15       32.8
```

Whereas the mean of the predictions from `heckman` is within 18 cents of the true mean wage, ordinary regression yields predictions that are on average about $1.80 per hour too high because of the selection effect. The regression predictions also show somewhat less variation than the true wages.

The coefficients from `heckman` are so close to the true values that they are not worth testing. Conversely, the regression equation is significantly off but seems to give the right sense. Would we be led far astray if we relied on the OLS coefficients? The effect of age is off by more than 5 cents per year of age, and the coefficient on education level is off by about 10%. We can test the OLS coefficient on education level against the true value by using `test`.

```
. test educ = 1
 ( 1)  education = 1
       F(  1,  1340) =    4.31
            Prob > F =    0.0380
```

Not only is the OLS coefficient on education substantially lower than the true parameter, but the difference from the true parameter is also statistically significant beyond the 5% level. We can perform a similar test for the OLS age coefficient:

```
. test age = .2
 ( 1)  age = .2
       F(  1,  1340) =    8.15
            Prob > F =    0.0044
```

We find even stronger evidence that the OLS regression results are biased away from the true parameters.

◁

▷ Example 2

Several other interesting aspects of the Heckman model can be explored with `predict`. Continuing with our wage model, we can obtain the expected wages for women conditional on participating in the labor force with the `ycond` option. Let's get these predictions and compare them with actual wages for women participating in the labor force.

```
. use http://www.stata-press.com/data/r12/womenwk, clear
. heckman wage educ age, select(married children educ age)
  (output omitted)
. predict hcndwage, ycond
. summarize wage hcndwage if wage != .
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
        wage |      1343    23.69217    6.305374    5.88497   45.80979
    hcndwage |      1343    23.68239    3.335087   16.18337    33.7567
```

We see that the average predictions from `heckman` are close to the observed levels but do not have the same mean. These conditional wage predictions are available for all observations in the dataset but can be directly compared only with observed wages, where individuals are participating in the labor force.

What if we were interested in making predictions about mean wages for all women? Here the expected wage is 0 for those who are not expected to participate in the labor force, with expected participation determined by the selection equation. These values can be obtained with the `yexpected` option of `predict`. For comparison, a variable can be generated where the wage is set to 0 for nonparticipants.

```
. predict hexpwage, yexpected
. generate wage0 = wage
(657 missing values generated)
. replace wage0 = 0 if wage == .
(657 real changes made)
```

```
. summarize hexpwage wage0
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
    hexpwage |       2000    15.92511    5.979336   2.492469   32.45858
       wage0 |       2000    15.90929    12.27081          0   45.80979
```

Again we note that the predictions from `heckman` are close to the observed mean hourly wage rate for all women. Why aren't the predictions using `ycond` and `yexpected` equal to their observed sample equivalents? For the Heckman model, unlike linear regression, the sample moments implied by the optimal solution to the model likelihood do not require that these predictions match observed data. Properly accounting for the additional variation from the selection equation requires that the model use more information than just the sample moments of the observed wages.

Title

heckprob — Probit model with sample selection

Syntax

```
heckprob depvar indepvars [if] [in] [weight],
    select([depvar_s =] varlist_s [, offset(varname) noconstant]) [options]
```

options	Description
Model	
* `select()`	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
`noconstant`	suppress constant term
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`first`	report first-step probit estimates
`noskip`	perform likelihood-ratio test
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

* `select()` is required.

The full specification is `select(`[*depvar*$_s$ `=`] *varlist*$_s$ [`, offset(`*varname*`) noconstant`]`)`.

indepvars and *varlist*$_s$ may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar, *indepvars*, *depvar*$_s$, and *varlist*$_s$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `first`, `noskip`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`pweights`, `fweights`, and `iweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Sample-selection models > Probit model with selection

Description

`heckprob` fits maximum-likelihood probit models with sample selection.

Options

Model

`select(...)` specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If $depvar_s$ is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If $depvar_s$ is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

`noconstant`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`noskip` specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test that all the parameters in the regression equation are zero (except the constant). For many models, this option can substantially increase estimation time.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with heckprob but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Remarks

The probit model with sample selection (Van de Ven and Van Pragg 1981) assumes that there exists an underlying relationship

$$y_j^* = \mathbf{x}_j\boldsymbol{\beta} + u_{1j} \qquad \textit{latent equation}$$

such that we observe only the binary outcome

$$y_j^{\text{probit}} = (y_j^* > 0) \qquad \textit{probit equation}$$

The dependent variable, however, is not always observed. Rather, the dependent variable for observation j is observed if

$$y_j^{\text{select}} = (\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0) \qquad \textit{selection equation}$$

where

$$u_1 \sim N(0,1)$$
$$u_2 \sim N(0,1)$$
$$\text{corr}(u_1, u_2) = \rho$$

When $\rho \neq 0$, standard probit techniques applied to the first equation yield biased results. heckprob provides consistent, asymptotically efficient estimates for all the parameters in such models.

For the model to be well identified, the selection equation should have at least one variable that is not in the probit equation. Otherwise, the model is identified only by functional form, and the coefficients have no structural interpretation.

▷ Example 1

We use the data from Pindyck and Rubinfeld (1998). In this dataset, the variables are whether children attend private school (private), number of years the family has been at the present residence (years), log of property tax (logptax), log of income (loginc), and whether one voted for an increase in property taxes (vote).

In this example, we alter the meaning of the data. Here we assume that we observe whether children attend private school only if the family votes for increasing the property taxes. This assumption is not true in the dataset, and we make it only to illustrate the use of this command.

We observe whether children attend private school only if the head of household voted for an increase in property taxes. We assume that the vote is affected by the number of years in residence, the current property taxes paid, and the household income. We wish to model whether children are sent to private school on the basis of the number of years spent in the current residence and the current property taxes paid.

```

------------------------------------------------------------------------------
LR test of indep. eqns. (rho = 0):   chi2(1) =     0.27   Prob > chi2 = 0.6020
```

The output shows several iteration logs. The first iteration log corresponds to running the probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe our outcome of interest. If $\rho = 0$, the sum of the log likelihoods from these two models will equal the log likelihood of the probit model with sample selection; this sum is printed in the iteration log as the comparison log likelihood. The third iteration log shows starting values for the iterations.

The final iteration log is for fitting the full probit model with sample selection. A likelihood-ratio test of the log likelihood for this model and the comparison log likelihood is presented at the end of the output. If we had specified the `vce(robust)` option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

◁

▷ Example 2

In example 1, we could have obtained robust standard errors by specifying the `vce(robust)` option. We do this here and also eliminate the iteration logs by using the `nolog` option:

```
. heckprob private years logptax, sel(vote=years loginc logptax) vce(robust) nolog
Probit model with sample selection              Number of obs      =        95
                                                Censored obs       =        36
                                                Uncensored obs     =        59
                                                Wald chi2(2)       =      2.55
Log pseudolikelihood = -74.24497                Prob > chi2        =    0.2798
```

	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
private						
years	-.1142597	.1113977	-1.03	0.305	-.3325951	.1040758
logptax	.3516098	.7358265	0.48	0.633	-1.090584	1.793803

logptax	-1.278783	.5095156	-2.51	0.012	-2.277415	-.2801508
_cons	-.545821	4.543892	-0.12	0.904	-9.451686	8.360044
/athrho	-.8663156	1.630643	-0.53	0.595	-4.062318	2.329687
rho	-.6994973	.8327753			-.9994079	.981233

```
Wald test of indep. eqns. (rho = 0): chi2(1) =     0.28   Prob > chi2 = 0.5952
```

Regardless of whether we specify the `vce(robust)` option, the outcome is not significantly different from the outcome obtained by fitting the probit and selection models separately. This result is not surprising because the selection mechanism estimated was invented for the example rather than borne from any economic theory.

◁

Saved results

heckprob saves the following in e():

Scalars

e(N)	number of observations
e(N_cens)	number of censored observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_aux)	number of auxiliary parameters
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(ll_c)	log likelihood, comparison model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(chi2_c)	χ^2 for comparison test
e(p_c)	p-value for comparison test
e(p)	significance of comparison test
e(rho)	ρ
e(rank)	rank of e(V)
e(rank0)	rank of e(V) for constant-only model
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	heckprob
e(cmdline)	command as typed
e(depvar)	names of dependent variables
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset1)	offset for regression equation
e(offset2)	offset for selection equation
e(chi2type)	Wald or LR; type of model χ^2 test
e(chi2_ct)	type of comparison χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

`heckprob` is implemented as an ado-file. Van de Ven and Van Pragg (1981) provide an introduction and an explanation of this model.

The probit equation is

$$y_j = (\mathbf{x}_j\boldsymbol{\beta} + u_{1j} > 0)$$

The selection equation is

$$\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0$$

where

$$u_1 \sim N(0,1)$$
$$u_2 \sim N(0,1)$$
$$\text{corr}(u_1, u_2) = \rho$$

The log likelihood is

$$\begin{aligned}\ln L = &\sum_{\substack{j\in S\\ y_j\neq 0}} w_j \ln\left\{\Phi_2\left(x_j\beta + \text{offset}_j^{\beta}, z_j\gamma + \text{offset}_j^{\gamma}, \rho\right)\right\}\\ &+ \sum_{\substack{j\in S\\ y_j=0}} w_j \ln\left\{\Phi_2\left(-x_j\beta + \text{offset}_j^{\beta}, z_j\gamma + \text{offset}_j^{\gamma}, -\rho\right)\right\}\\ &+ \sum_{j\notin S} w_j \ln\left\{1 - \Phi\left(z_j\gamma + \text{offset}_j^{\gamma}\right)\right\}\end{aligned}$$

where S is the set of observations for which y_j is observed, $\Phi_2(\cdot)$ is the cumulative bivariate normal distribution function (with mean $[\,0\ \ 0\,]'$), $\Phi(\cdot)$ is the standard cumulative normal, and w_j is an optional weight for observation j.

In the maximum likelihood estimation, ρ is not directly estimated. Directly estimated is atanh ρ:

$$\text{atanh}\,\rho = \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right)$$

From the form of the likelihood, it is clear that if $\rho = 0$, the log likelihood for the probit model with sample selection is equal to the sum of the probit model for the outcome y and the selection model. We can perform a likelihood-ratio test by comparing the likelihood of the full model with the sum of the log likelihoods for the probit and selection models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`heckprob` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

heckprob postestimation — Postestimation tools for heckprob

Description

The following postestimation commands are available after `heckprob`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]

predict [type] {stub* | newvar_reg newvar_sel newvar_athrho} [if] [in], scores
```

statistic	Description
Main	
pmargin	$\Phi(\mathbf{x}_j\mathbf{b})$, success probability; the default
p11	$\Phi_2(\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, \rho)$, predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$
p10	$\Phi_2(\mathbf{x}_j\mathbf{b}, -\mathbf{z}_j\mathbf{g}, -\rho)$, predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$
p01	$\Phi_2(-\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, -\rho)$, predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$
p00	$\Phi_2(-\mathbf{x}_j\mathbf{b}, -\mathbf{z}_j\mathbf{g}, \rho)$, predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$
psel	$\Phi(\mathbf{z}_j\mathbf{g})$, selection probability
pcond	$\Phi_2(\mathbf{x}_j\mathbf{b}, \mathbf{z}_j\mathbf{g}, \rho)/\Phi(\mathbf{z}_j\mathbf{g})$, probability of success conditional on selection
xb	linear prediction
stdp	standard error of the linear prediction
xbsel	linear prediction for selection equation
stdpsel	standard error of the linear prediction for selection equation

where $\Phi(\cdot)$ is the standard normal distribution function and $\Phi_2(\cdot)$ is the bivariate normal distribution function.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pmargin`, the default, calculates the univariate (marginal) predicted probability of success $\Pr(y_j^{\text{probit}} = 1)$.

`p11` calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$.

`p10` calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$.

`p01` calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$.

`p00` calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$.

`psel` calculates the univariate (marginal) predicted probability of selection $\Pr(y_j^{\text{select}} = 1)$.

`pcond` calculates the conditional (on selection) predicted probability of success $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)/\Pr(y_j^{\text{select}} = 1)$.

`xb` calculates the probit linear prediction $\mathbf{x}_j\mathbf{b}$.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbsel` calculates the linear prediction for the selection equation.

`stdpsel` calculates the standard error of the linear prediction for the selection equation.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `heckprob`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\mathbf{z}_j\boldsymbol{\gamma})$.

The third new variable will contain $\partial \ln L/\partial(\text{atanh}\,\rho)$.

Remarks

▷ Example 1

It is instructive to compare the marginal predicted probabilities with the predicted probabilities that we would obtain by ignoring the selection mechanism. To compare the two approaches, we will synthesize data so that we know the "true" predicted probabilities.

First, we need to generate correlated error terms, which we can do using a standard Cholesky decomposition approach. For our example, we will clear any data from memory and then generate errors that have a correlation of 0.5 by using the following commands. We set the seed so that interested readers can type in these same commands and obtain the same results.

```
. set seed 12309
. set obs 5000
obs was 0, now 5000
. gen c1 = rnormal()
. gen c2 = rnormal()
. matrix P = (1,.5\.5,1)
. matrix A = cholesky(P)
. local fac1 = A[2,1]
. local fac2 = A[2,2]
. gen u1 = c1
. gen u2 = `fac1'*c1 + `fac2'*c2
```

We can check that the errors have the correct correlation by using the `correlate` command. We will also normalize the errors so that they have a standard deviation of one, so we can generate a bivariate probit model with known coefficients. We do that with the following commands:

```
. correlate u1 u2
(obs=5000)
             |       u1       u2
-------------+------------------
          u1 |   1.0000
          u2 |   0.5020   1.0000

. summarize u1
  (output omitted)
. replace u1 = u1/r(sd)
(5000 real changes made)
. summarize u2
  (output omitted)
. replace u2 = u2/r(sd)
(5000 real changes made)
. drop c1 c2
. gen x1 = runiform()-.5
. gen x2 = runiform()+1/3
. gen y1s = 0.5 + 4*x1 + u1
. gen y2s = 3 - 3*x2 + .5*x1 + u2
. gen y1 = (y1s>0)
. gen y2 = (y2s>0)
```

We have now created two dependent variables, `y1` and `y2`, which are defined by our specified coefficients. We also included error terms for each equation, and the error terms are correlated. We run `heckprob` to verify that the data have been correctly generated according to the model

$$y_1 = .5 + 4x_1 + u_1$$
$$y_2 = 3 + .5x_1 - 3x_2 + u_2$$

where we assume that y_1 is observed only if $y_2 = 1$.

```
. heckprob y1 x1, sel(y2 = x1 x2) nolog
Probit model with sample selection              Number of obs      =      5000
                                                Censored obs       =      1762
                                                Uncensored obs     =      3238

                                                Wald chi2(1)       =    953.71
Log likelihood =   -3679.5                      Prob > chi2        =    0.0000

------------------------------------------------------------------------------
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
y1           |
          x1 |   3.784705   .1225532    30.88   0.000     3.544505    4.024905
       _cons |   .4630922   .0453952    10.20   0.000     .3741192    .5520653
-------------+----------------------------------------------------------------
y2           |
          x1 |   .3693052   .0721694     5.12   0.000     .2278558    .5107547
          x2 |  -3.05069    .0832424   -36.65   0.000    -3.213842   -2.887538
       _cons |   3.037696   .0777733    39.06   0.000     2.885263    3.190128
-------------+----------------------------------------------------------------
     /athrho |   .5186232    .083546     6.21   0.000      .354876    .6823705
-------------+----------------------------------------------------------------
         rho |   .4766367   .0645658                      .3406927    .5930583
------------------------------------------------------------------------------
LR test of indep. eqns. (rho = 0):   chi2(1) =    40.43   Prob > chi2 = 0.0000
```

Now that we have verified that we have generated data according to a known model, we can obtain and then compare predicted probabilities from the probit model with sample selection and a (usual) probit model.

```
. predict pmarg
(option pmargin assumed; Pr(y1=1))
. probit y1 x1 if y2==1
  (output omitted)
. predict phat
(option pr assumed; Pr(y1))
```

Using the (marginal) predicted probabilities from the probit model with sample selection (`pmarg`) and the predicted probabilities from the (usual) probit model (`phat`), we can also generate the "true" predicted probabilities from the synthesized `y1s` variable and then compare the predicted probabilities:

```
. gen ptrue = normal(y1s)
. summarize pmarg ptrue phat
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
       pmarg |       5000    .6071226    .3147861   .0766334   .9907113
       ptrue |       5000    .5974195     .348396   5.53e-06   .9999999
        phat |       5000    .6568175    .3025085   .1059824   .9954919
```

Here we see that ignoring the selection mechanism (comparing the `phat` variable with the true `ptrue` variable) results in predicted probabilities that are much higher than the true values. Looking at the marginal predicted probabilities from the model with sample selection, however, results in more accurate predictions.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

[R] **heckprob** — Probit model with sample selection

[U] **20 Estimation and postestimation commands**

Title

help — Display online help

Syntax

Display help information in Viewer

help [*command_or_topic_name*] [, nonew name(*viewername*) marker(*markername*)]

Display help information in Results window

chelp [*command_or_topic_name*]

Menu

Help > Stata Command...

Description

The help command displays help information about the specified command or topic.

Stata for Mac, Stata for Unix(GUI), and Stata for Windows:
help launches a new Viewer to display help for the specified command or topic. If help is not followed by a command or a topic name, Stata launches the Viewer and displays help contents, the table of contents for the online help.

Help may be accessed either by selecting **Help > Stata Command...** and filling in the desired command name or by typing help followed by a command or topic name.

chelp will display help in the Results window.

Stata for Unix(console):
Typing help followed by a command name or a topic name will display help on the console.

If help is not followed by a command or a topic name, a description of how to use the help system is displayed.

Stata for Unix(both GUI and console):
man is a synonym for chelp.

Options

nonew specifies that a new Viewer window not be opened for the help topic if a Viewer window is already open. The default is for a new Viewer window to be opened each time help is typed so that multiple help files may be viewed at once. nonew causes the help file to be displayed in the topmost open Viewer.

name(*viewername*) specifies that help be displayed in a Viewer window named *viewername*. If the named window already exists, its contents will be replaced. If the named window does not exist, it will be created.

`marker(`*markername*`)` specifies that the help file be opened to the position of *markername* within the help file.

Remarks

To obtain help for any Stata command, type `help` *command* or select **Help > Stata Command...** and fill in *command*.

`help` is best explained by examples.

To obtain help for . . .	type
`regress`	`help regress`
postestimation tools for `regress`	`help regress postestimation` or `help regress post`
graph option `xlabel()`	`help graph xlabel()`
Stata function `strpos()`	`help strpos()`
Mata function `optimize()`	`help mata optimize()`

Tips:

- `help` displays a subject table of contents for the online help.
- `help guide` displays a table of contents for basic Stata concepts.
- `help estimation commands` displays an alphabetical listing of all Stata estimation commands.
- `help functions` displays help on Stata functions by category.
- `help mata functions` displays a subject table of contents for Mata's functions.
- `help ts glossary` displays the glossary for the time-series manual, and similarly for the other Stata specialty manuals.

See [U] **4 Stata's help and search facilities** for a complete description of how to use `help`.

❑ Technical note

When you type `help` *topic*, Stata first looks along the adopath for *topic*`.sthlp`; see [U] **17.5 Where does Stata look for ado-files?**. ❑

Title

hetprob — Heteroskedastic probit model

Syntax

```
hetprob depvar [indepvars] [if] [in] [weight] ,
    het(varlist[ , offset(varname)]) [options]
```

options	Description
Model	
*`het(varlist[...])`	independent variables to model the variance and possible offset variable
`noconstant`	suppress constant term
`offset(varname)`	include *varname* in model with coefficient constrained to 1
`asis`	retain perfect predictor variables
`constraints(constraints)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(vcetype)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`noskip`	perform likelihood-ratio test
`nolrtest`	perform Wald test on variance
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

*`het()` is required. The full specification is `het(`*varlist*` [ , offset(`*varname*`) ])`.

indepvars and *varlist* may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar, *indepvars*, and *varlist* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `noskip`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Binary outcomes > Heteroskedastic probit regression

Description

`hetprob` fits a maximum-likelihood heteroskedastic probit model.

See [R] **logistic** for a list of related estimation commands.

Options

Model

`het(`*varlist* [`, offset(`*varname*`)`]`)` specifies the independent variables and the offset variable, if there is one, in the variance function. `het()` is required.

`noconstant`, `offset(`*varname*`)`; see [R] **estimation options**.

`asis` forces the retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`noskip` requests fitting of the constant-only model and calculation of the corresponding likelihood-ratio χ^2 statistic for testing significance of the full model. By default, a Wald χ^2 statistic is computed for testing the significance of the full model.

`nolrtest` specifies that a Wald test of whether `lnsigma2` $= 0$ be performed instead of the LR test.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, [`no`]`log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `hetprob` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Robust standard errors

Introduction

`hetprob` fits a maximum-likelihood heteroskedastic probit model, which is a generalization of the probit model. Let $y_j, j = 1, \ldots, N$, be a binary outcome variable taking on the value 0 (failure) or 1 (success). In the probit model, the probability that y_j takes on the value 1 is modeled as a nonlinear function of a linear combination of the k independent variables $\mathbf{x}_j = (x_{1j}, x_{2j}, \ldots, x_{kj})$,

$$\Pr(y_j = 1) = \Phi(\mathbf{x}_j\mathbf{b})$$

in which $\Phi()$ is the cumulative distribution function (CDF) of a standard normal random variable, that is, a normally distributed (Gaussian) random variable with mean 0 and variance 1. The linear combination of the independent variables, $\mathbf{x}_j\mathbf{b}$, is commonly called the *index function*, or *index*. Heteroskedastic probit generalizes the probit model by generalizing $\Phi()$ to a normal CDF with a variance that is no longer fixed at 1 but can vary as a function of the independent variables. `hetprob` models the variance as a multiplicative function of these m variables $\mathbf{z}_j = (z_{1j}, z_{2j}, \ldots, z_{mj})$, following Harvey (1976):

$$\sigma_j^2 = \{\exp(\mathbf{z}_j\boldsymbol{\gamma})\}^2$$

Thus the probability of success as a function of all the independent variables is

$$\Pr(y_j = 1) = \Phi\Big\{\mathbf{x}_j\mathbf{b}/\exp(\mathbf{z}_j\boldsymbol{\gamma})\Big\}$$

From this expression, it is clear that, unlike the index $\mathbf{x}_j\mathbf{b}$, no constant term can be present in $\mathbf{z}_j\boldsymbol{\gamma}$ if the model is to be identifiable.

Suppose that the binary outcomes y_j are generated by thresholding an unobserved random variable, w, which is normally distributed with mean $\mathbf{x}_j\mathbf{b}$ and variance 1 such that

$$y_j = \begin{cases} 1 & \text{if } w_j > 0 \\ 0 & \text{if } w_j \leq 0 \end{cases}$$

This process gives the probit model:

$$\Pr(y_j = 1) = \Pr(w_j > 0) = \Phi(\mathbf{x}_j\mathbf{b})$$

Now suppose that the unobserved w_j are heteroskedastic with variance

$$\sigma_j^2 = \{\exp(\mathbf{z}_j\boldsymbol{\gamma})\}^2$$

Relaxing the homoskedastic assumption of the probit model in this manner yields our multiplicative heteroskedastic probit model:

$$\Pr(y_j = 1) = \Phi\Big\{\mathbf{x}_j\mathbf{b}/\exp(\mathbf{z}_j\boldsymbol{\gamma})\Big\}$$

Example 1

For this example, we generate simulated data for a simple heteroskedastic probit model and then estimate the coefficients with `hetprob`:

```
. set obs 1000
obs was 0, now 1000
. set seed 1234567
. gen x = 1-2*runiform()
. gen xhet = runiform()
. gen sigma = exp(1.5*xhet)
. gen p = normal((0.3+2*x)/sigma)
. gen y = cond(runiform()<=p,1,0)
. hetprob y x, het(xhet)
Fitting probit model:
Iteration 0:   log likelihood = -688.53208
Iteration 1:   log likelihood = -591.59895
Iteration 2:   log likelihood = -591.50674
Iteration 3:   log likelihood = -591.50674
Fitting full model:
Iteration 0:   log likelihood = -591.50674
Iteration 1:   log likelihood = -572.12219
Iteration 2:   log likelihood =  -570.7742
Iteration 3:   log likelihood = -569.48921
Iteration 4:   log likelihood = -569.47828
Iteration 5:   log likelihood = -569.47827
Heteroskedastic probit model                    Number of obs     =       1000
                                                Zero outcomes     =        452
                                                Nonzero outcomes  =        548
                                                Wald chi2(1)      =      78.66
Log likelihood = -569.4783                      Prob > chi2       =     0.0000
```

y	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
y						
x	2.228031	.2512073	8.87	0.000	1.735673	2.720388
_cons	.2493822	.0862833	2.89	0.004	.08027	.4184943
lnsigma2						
xhet	1.602537	.2640131	6.07	0.000	1.085081	2.119993

```
Likelihood-ratio test of lnsigma2=0: chi2(1) =    44.06   Prob > chi2 = 0.0000
```

Above we created two variables, `x` and `xhet`, and then simulated the model

$$\Pr(\mathtt{y}=1) = F\left\{(\beta_0+\beta_1\mathtt{x})/\exp(\gamma_1\mathtt{xhet})\right\}$$

for $\beta_0 = 0.3$, $\beta_1 = 2$, and $\gamma_1 = 1.5$. According to `hetprob`'s output, all coefficients are significant, and, as we would expect, the Wald test of the full model versus the constant-only model—for example, the index consisting of $\beta_0+\beta_1\mathtt{x}$ versus that of just β_0—is significant with $\chi^2(1) = 79$. Likewise, the likelihood-ratio test of heteroskedasticity, which tests the full model with heteroskedasticity against the full model without, is significant with $\chi^2(1) = 44$. See [R] **maximize** for more explanation of the output. For this simple model, `hetprob` took five iterations to converge. As stated elsewhere (Greene 2012, 714), this is a difficult model to fit, and it is not uncommon for it to require many iterations or for the optimizer to print out warnings and informative messages during the optimization. Slow convergence is especially common for models in which one or more of the independent variables appear in both the index and variance functions. ◁

❑ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

❑

Robust standard errors

If you specify the `vce(robust)` option, `hetprob` reports robust standard errors as described in [U] **20.20 Obtaining robust variance estimates**. To illustrate the effect of this option, we will reestimate our coefficients by using the same model and data in our example, this time adding `vce(robust)` to our `hetprob` command.

▷ Example 2

```
. hetprob y x, het(xhet) vce(robust) nolog
Heteroskedastic probit model                      Number of obs     =       1000
                                                  Zero outcomes     =        452
                                                  Nonzero outcomes  =        548
                                                  Wald chi2(1)      =      65.23
Log pseudolikelihood = -569.4783                  Prob > chi2       =     0.0000
```

y	Coef.	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
y						
x	2.22803	.2758597	8.08	0.000	1.687355	2.768705
_cons	.2493821	.0843367	2.96	0.003	.0840853	.4146789
lnsigma2						
xhet	1.602537	.2671326	6.00	0.000	1.078967	2.126107

```
Wald test of lnsigma2=0:              chi2(1) =    35.99   Prob > chi2 = 0.0000
```

The `vce(robust)` standard errors for two of the three parameters are larger than the previously reported conventional standard errors. This is to be expected, even though (by construction) we have perfect model specification because this option trades off efficient estimation of the coefficient variance–covariance matrix for robustness against misspecification.

◁

Specifying the `vce(cluster` *clustvar*`)` option relaxes the usual assumption of independence between observations to the weaker assumption of independence just between clusters; that is, `hetprob, vce(cluster` *clustvar*`)` is robust with respect to within-cluster correlation. This option is less efficient than the `xtgee` population-averaged models because `hetprob` inefficiently sums within cluster for the standard-error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

Saved results

hetprob saves the following in e():

Scalars

e(N)	number of observations
e(N_f)	number of zero outcomes
e(N_s)	number of nonzero outcomes
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(ll_c)	log likelihood, comparison model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(chi2_c)	χ^2 for heteroskedasticity LR test
e(p_c)	p-value for heteroskedasticity LR test
e(df_m_c)	degrees of freedom for heteroskedasticity LR test
e(p)	significance
e(rank)	rank of e(V)
e(rank0)	rank of e(V) for constant-only model
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	hetprob
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset1)	offset for probit equation
e(offset2)	offset for variance equation
e(chi2type)	Wald or LR; type of model χ^2 test
e(chi2_ct)	Wald or LR; type of model χ^2 test corresponding to e(chi2_c)
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(method)	requested estimation method
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

`hetprob` is implemented as an ado-file.

The heteroskedastic probit model is a generalization of the probit model because it allows the scale of the inverse link function to vary from observation to observation as a function of the independent variables.

The log-likelihood function for the heteroskedastic probit model is

$$\ln L = \sum_{j \in S} w_j \ln \Phi\{\mathbf{x}_j\boldsymbol{\beta}/\exp(\mathbf{z}\boldsymbol{\gamma})\} + \sum_{j \notin S} w_j \ln\left[1 - \Phi\{\mathbf{x}_j\boldsymbol{\beta}/\exp(\mathbf{z}\boldsymbol{\gamma})\}\right]$$

where S is the set of all observations j such that $y_j \neq 0$ and w_j denotes the optional weights. $\ln L$ is maximized as described in [R] **maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`hetprob` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

hetprob postestimation — Postestimation tools for hetprob

Description

The following postestimation commands are available after `hetprob`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat (svy)`.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` *statistic* `nooffset`]

`predict` [*type*] { *stub*`*` | *newvar*$_{\text{reg}}$ *newvar*$_{\text{lnsigma2}}$ } [*if*] [*in*] `,` `scores`

statistic	Description
Main	
`pr`	probability of a positive outcome; the default
`xb`	linear prediction
`sigma`	standard deviation of the error term

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`sigma` calculates the standard deviation of the error term.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `hetprob`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\mathbf{z}_j\boldsymbol{\gamma})$.

Remarks

Once you have fit a model, you can use the `predict` command to obtain the predicted probabilities for both the estimation sample and other samples; see [U] **20 Estimation and postestimation commands** and [R] **predict**. `predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the index function combination, $\mathbf{x}_j\mathbf{b}$, where $\mathbf{x}_j$ are the independent variables in the jth observation and $\mathbf{b}$ is the estimated parameter vector. With the `sigma` option, `predict` calculates the predicted standard deviation, $\sigma_j = \exp(\mathbf{z}_j\boldsymbol{\gamma})$.

▷ Example 1

We use `predict` to compute the predicted probabilities and standard deviations based on the model in example 2 in [R] **hetprob** to compare these with the actual values:

```
. predict phat
(option pr assumed; Pr(y))
. gen diff_p = phat - p
. summarize diff_p
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
      diff_p |      1000   -.0107081    .0131869  -.0466331    .010482
. predict sigmahat, sigma
. gen diff_s = sigmahat - sigma
. summarize diff_s
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
      diff_s |      1000    .1558881    .1363698   .0000417   .4819107
```

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

histogram — Histograms for continuous and categorical variables

Syntax

`histogram` *varname* [*if*] [*in*] [*weight*] [, [*continuous_opts* | *discrete_opts*] *options*]

continuous_opts	Description
Main	
`bin(#)`	set number of bins to #
`width(#)`	set width of bins to #
`start(#)`	set lower limit of first bin to #

discrete_opts	Description
Main	
`discrete`	specify that data are discrete
`width(#)`	set width of bins to #
`start(#)`	set theoretical minimum value to #

options	Description
Main	
`density`	draw as density; the default
`fraction`	draw as fractions
`frequency`	draw as frequencies
`percent`	draw as percentages
bar_options	rendition of bars
`addlabels`	add height labels to bars
`addlabopts(`*marker_label_options*`)`	affect rendition of labels
Density plots	
`normal`	add a normal density to the graph
`normopts(`*line_options*`)`	affect rendition of normal density
`kdensity`	add a kernel density estimate to the graph
`kdenopts(`*kdensity_options*`)`	affect rendition of kernel density
Add plots	
`addplot(`*plot*`)`	add other plots to the histogram
Y axis, X axis, Titles, Legend, Overall, By	
twoway_options	any options documented in [G-3] ***twoway_options***

`fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Graphics > Histogram

Description

`histogram` draws histograms of *varname*, which is assumed to be the name of a continuous variable unless the `discrete` option is specified.

Options for use in the continuous case

Main

`bin(#)` and `width(#)` are alternatives. They specify how the data are to be aggregated into bins: `bin()` by specifying the number of bins (from which the width can be derived) and `width()` by specifying the bin width (from which the number of bins can be derived).

If neither option is specified, results are the same as if `bin(`*k*`)` had been specified, where

$$k = \min\left\{\text{sqrt}(N), 10\ln(N)/\ln(10)\right\}$$

and where N is the (weighted) number of observations.

`start(#)` specifies the theoretical minimum of *varname*. The default is `start(`*m*`)`, where *m* is the observed minimum value of *varname*.

Specify `start()` when you are concerned about sparse data, for instance, if you know that *varname* can have a value of 0, but you are concerned that 0 may not be observed.

`start(#)`, if specified, must be less than or equal to *m*, or else an error will be issued.

Options for use in the discrete case

Main

`discrete` specifies that *varname* is discrete and that you want each unique value of *varname* to have its own bin (bar of histogram).

`width(#)` is rarely specified in the discrete case; it specifies the width of the bins. The default is `width(`*d*`)`, where *d* is the observed minimum difference between the unique values of *varname*.

Specify `width()` if you are concerned that your data are sparse. For example, in theory *varname* could take on the values, say, 1, 2, 3, ..., 9, but because of the sparseness, perhaps only the values 2, 4, 7, and 8 are observed. Here the default width calculation would produce `width(2)`, and you would want to specify `width(1)`.

`start(#)` is also rarely specified in the discrete case; it specifies the theoretical minimum value of *varname*. The default is `start(`*m*`)`, where *m* is the observed minimum value.

As with `width()`, specify `start(#)` if you are concerned that your data are sparse. In the previous example, you might also want to specify `start(1)`. `start()` does nothing more than add white space to the left side of the graph.

The value of # in `start()` must be less than or equal to *m*, or an error will be issued.

Options for use in both the continuous and discrete cases

Main

`density`, `fraction`, `frequency`, and `percent` specify whether you want the histogram scaled to density units, fractional units, frequencies, or percentages. `density` is the default.

`density` scales the height of the bars so that the sum of their areas equals 1.

`fraction` scales the height of the bars so that the sum of their heights equals 1.

`frequency` scales the height of the bars so that each bar's height is equal to the number of observations in the category. Thus the sum of the heights is equal to the total number of observations.

`percent` scales the height of the bars so that the sum of their heights equals 100.

bar_options are any of the options allowed by `graph twoway bar`; see [G-2] **graph twoway bar**.

One of the most useful *bar_options* is `barwidth(#)`, which specifies the width of the bars in *varname* units. By default, `histogram` draws the bars so that adjacent bars just touch. If you want gaps between the bars, do not specify `histogram`'s `width()` option—which would change how the histogram is calculated—but specify the *bar_option* `barwidth()` or the `histogram` option `gap`, both of which affect only how the bar is rendered.

The *bar_option* `horizontal` cannot be used with the `addlabels` option.

`addlabels` specifies that the top of each bar be labeled with the density, fraction, or frequency, as determined by the `density`, `fraction`, and `frequency` options.

`addlabopts(`*marker_label_options*`)` specifies how to render the labels atop the bars. See [G-3] ***marker_label_options***. Do not specify the *marker_label_option* `mlabel(`*varname*`)`, which specifies the variable to be used; this is specified for you by `histogram`.

`addlabopts()` will accept more options than those documented in [G-3] ***marker_label_options***. All options allowed by `twoway scatter` are also allowed by `addlabopts()`; see [G-2] **graph twoway scatter**. One particularly useful option is `yvarformat()`; see [G-3] ***advanced_options***.

Density plots

`normal` specifies that the histogram be overlaid with an appropriately scaled normal density. The normal will have the same mean and standard deviation as the data.

`normopts(`*line_options*`)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-2] **graph twoway line**.

`kdensity` specifies that the histogram be overlaid with an appropriately scaled kernel density estimate of the density. By default, the estimate will be produced using the Epanechnikov kernel with an "optimal" half-width. This default corresponds to the default of `kdensity`; see [R] **kdensity**. How the estimate is produced can be controlled using the `kdenopts()` option described below.

`kdenopts(`*kdensity_options*`)` specifies details about how the kernel density estimate is to be produced along with details about the rendition of the resulting curve, such as the color and style of line used. The kernel density estimate is described in [G-2] **graph twoway kdensity**. As an example, if you wanted to produce kernel density estimates by using the Gaussian kernel with optimal half-width, you would specify `kdenopts(gauss)` and if you also wanted a half-width of 5, you would specify `kdenopts(gauss width(5))`.

Add plots

`addplot(`*plot*`)` allows adding more `graph twoway` plots to the graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall, By

twoway_options are any of the options documented in [G-3] ***twoway_options***. This includes, most importantly, options for titling the graph (see [G-3] ***title_options***), options for saving the graph to disk (see [G-3] ***saving_option***), and the `by()` option, which will allow you to simultaneously graph histograms for different subsets of the data (see [G-3] ***by_option***).

Remarks

Remarks are presented under the following headings:

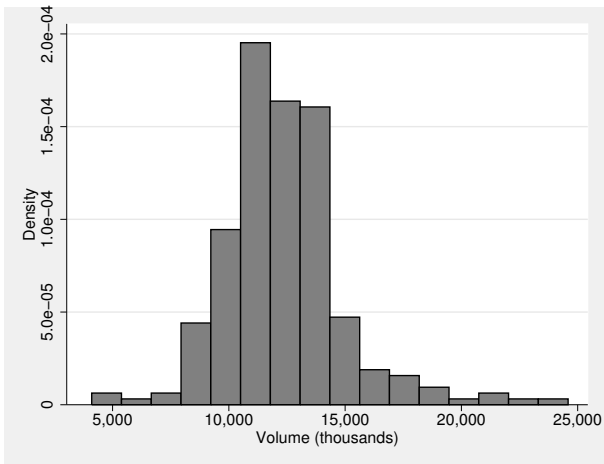
Histograms of continuous variables
Overlaying normal and kernel density estimates
Histograms of discrete variables
Use with by()

For an example of editing a histogram with the Graph Editor, see Pollock (2011, 29–31).

Histograms of continuous variables

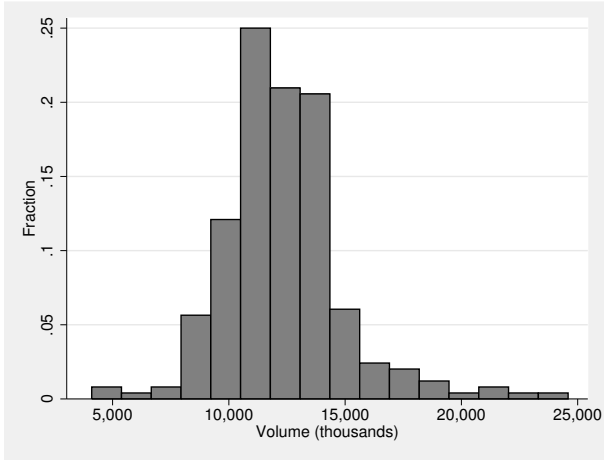
`histogram` assumes that the variable is continuous, so you need type only `histogram` followed by the variable name:

```
. use http://www.stata-press.com/data/r12/sp500
(S&P 500)
. histogram volume
(bin=15, start=4103, width=1280.3533)
```



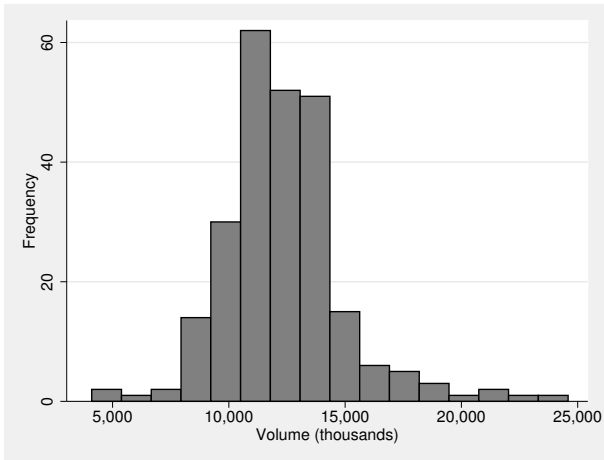
The small values reported for density on the y axis are correct; if you added up the area of the bars, you would get 1. Nevertheless, many people are used to seeing histograms scaled so that the bar heights sum to 1,

```
. histogram volume, fraction
(bin=15, start=4103, width=1280.3533)
```



and others are used to seeing histograms so that the bar height reflects the number of observations,

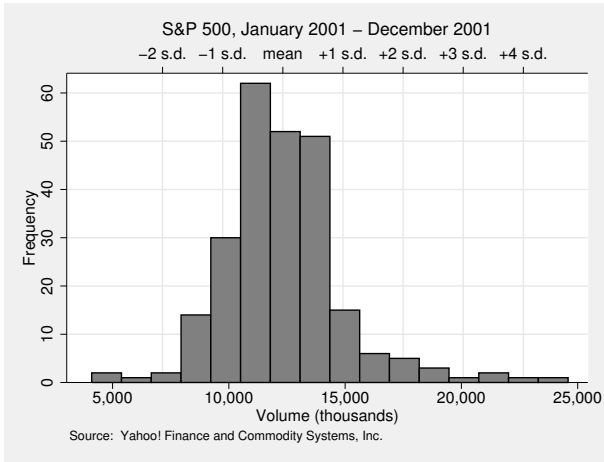
```
. histogram volume, frequency
(bin=15, start=4103, width=1280.3533)
```



Regardless of the scale you prefer, you can specify other options to make the graph look more impressive:

```
. summarize volume
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
      volume |        248    12320.68    2585.929      4103    23308.3

. histogram volume, freq
>         xaxis(1 2)
>         ylabel(0(10)60, grid)
>         xlabel(12321 "mean"
>                9735 "-1 s.d."
>               14907 "+1 s.d."
>                7149 "-2 s.d."
>               17493 "+2 s.d."
>               20078 "+3 s.d."
>               22664 "+4 s.d."
>                                , axis(2) grid gmax)
>         xtitle("", axis(2))
>         subtitle("S&P 500, January 2001 - December 2001")
>         note("Source:  Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)
```



For an explanation of the `xaxis()` option—it created the upper and lower x axis—see [G-3] ***axis_choice_options***. For an explanation of the `ylabel()` and `xlabel()` options, see [G-3] ***axis_label_options***. For an explanation of the `subtitle()` and `note()` options, see [G-3] ***title_options***.

Overlaying normal and kernel density estimates

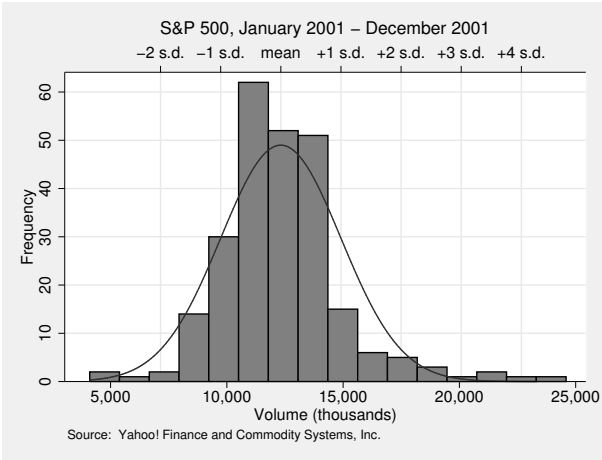
Specifying `normal` will overlay a normal density over the histogram. It would be enough to type

```
. histogram volume, normal
```

but we will add the option to our more impressive rendition:

```
. summarize volume
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
      volume |        248    12320.68    2585.929      4103    23308.3
```

```
. histogram volume, freq normal
>         xaxis(1 2)
>         ylabel(0(10)60, grid)
>         xlabel(12321 "mean"
>                9735 "-1 s.d."
>               14907 "+1 s.d."
>                7149 "-2 s.d."
>               17493 "+2 s.d."
>               20078 "+3 s.d."
>               22664 "+4 s.d."
>                                , axis(2) grid gmax)
>         xtitle("", axis(2))
>         subtitle("S&P 500, January 2001 - December 2001")
>         note("Source:  Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)
```



If we instead wanted to overlay a kernel density estimate, we could specify `kdensity` in place of `normal`.

Histograms of discrete variables

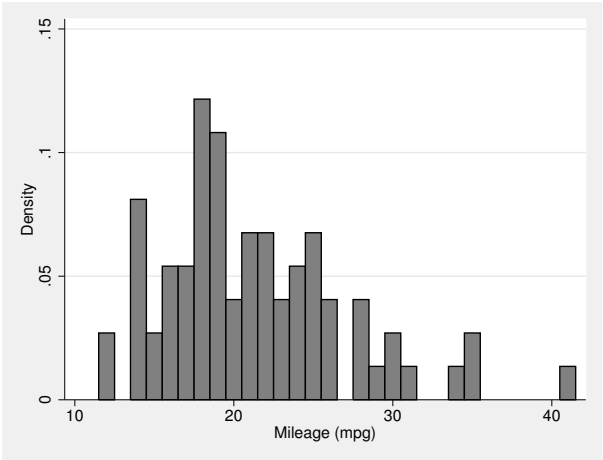
Specify `histogram`'s discrete option when you wish to treat the data as discrete—when you wish each unique value of the variable to be assigned its own bin. For instance, in the automobile data, `mpg` is a continuous variable, but the mileage ratings have been measured to integer precision. If we were to type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. histogram mpg
(bin=8, start=12, width=3.625)
```

`mpg` would be treated as continuous and categorized into eight bins by the default number-of-bins calculation, which is based on the number of observations, 74.

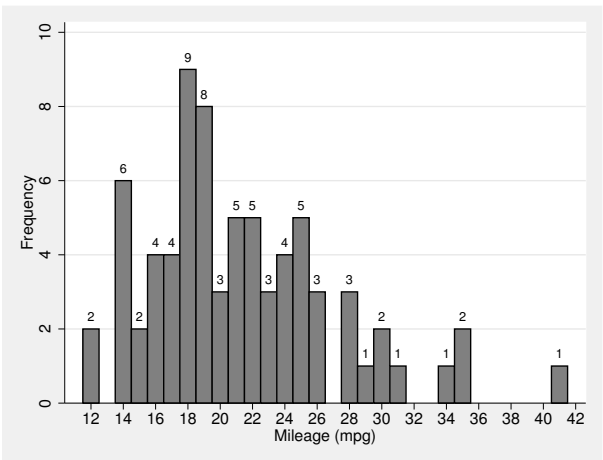
Adding the `discrete` option makes a histogram with a bin for each of the 21 unique values.

```
. histogram mpg, discrete
(start=12, width=1)
```



Just as in the continuous case, the y axis was reported in density, and we could specify the `fraction` or `frequency` options if we wanted it to be reported differently. Below we specify `frequency`, we specify `addlabels` to add a report of frequencies printed above the bars, we specify `ylabel(,grid)` to add horizontal grid lines, and we specify `xlabel(12(2)42)` to label the values 12, 14, ..., 42 on the x axis:

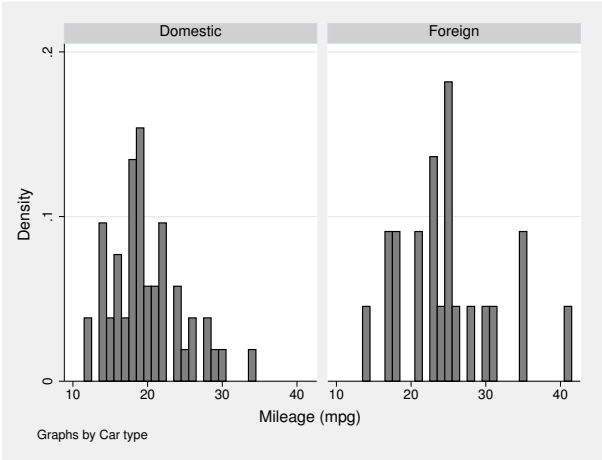
```
. histogram mpg, discrete freq addlabels ylabel(,grid) xlabel(12(2)42)
(start=12, width=1)
```



Use with by()

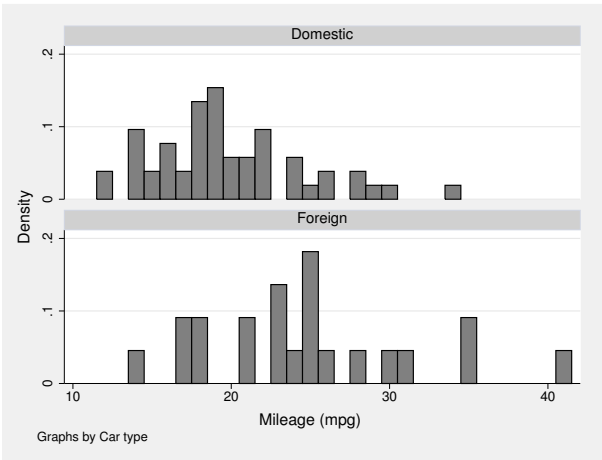
`histogram` may be used with `graph twoway`'s `by()`; for example,

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. histogram mpg, discrete by(foreign)
```



Here results would be easier to compare if the graphs were presented in one column:

```
. histogram mpg, discrete by(foreign, col(1))
```



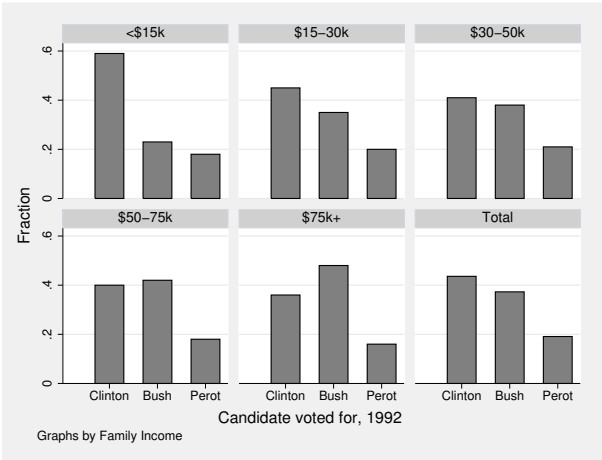
`col(1)` is a `by()` suboption—see [G-3] ***by_option***—and there are other useful suboptions, such as `total`, which will add an overall total histogram. `total` is a suboption of `by()`, not an option of `histogram`, so you would type

```
. histogram mpg, discrete by(foreign, total)
```

and not `histogram mpg, discrete by(foreign) total`.

As another example, Lipset (1993) reprinted data from the *New York Times* (November 5, 1992) collected by the Voter Research and Surveys based on questionnaires completed by 15,490 U.S. presidential voters from 300 polling places on election day in 1992.

```
. use http://www.stata-press.com/data/r12/voter
. histogram candi [freq=pop], discrete fraction by(inc, total)
> gap(40) xlabel(2 3 4, valuelabel)
```



We specified `gap(40)` to reduce the width of the bars by 40%. We also used `xlabel()`'s `valuelabel` suboption, which caused our bars to be labeled "Clinton", "Bush", and "Perot", rather than 2, 3, and 4; see [G-3] ***axis_label_options***.

Methods and formulas

`histogram` is implemented as an ado-file.

Title

hsearch — Search help files

Syntax

`hsearch` *word*(*s*)

`hsearch` *word*(*s*)`, build`

`hsearch, build`

Description

`hsearch` *word*(*s*) searches the help files for *word*(*s*) and presents a clickable list in the Viewer.

`hsearch` *word*(*s*)`, build` does the same thing but builds a new index first.

`hsearch, build` rebuilds the index but performs no search.

Option

`build` forces the index that `hsearch` uses to be built or rebuilt.

The index is automatically built the first time you use `hsearch`, and it is automatically rebuilt if you have recently installed an ado-file update by using `update`; see [R] **update**. Thus the `build` option is rarely specified.

You should specify `build` if you have recently installed user-written ado-files by using `net install` (see [R] **net**) or `ssc` (see [R] **ssc**), or if you have recently updated any of your own help files.

Remarks

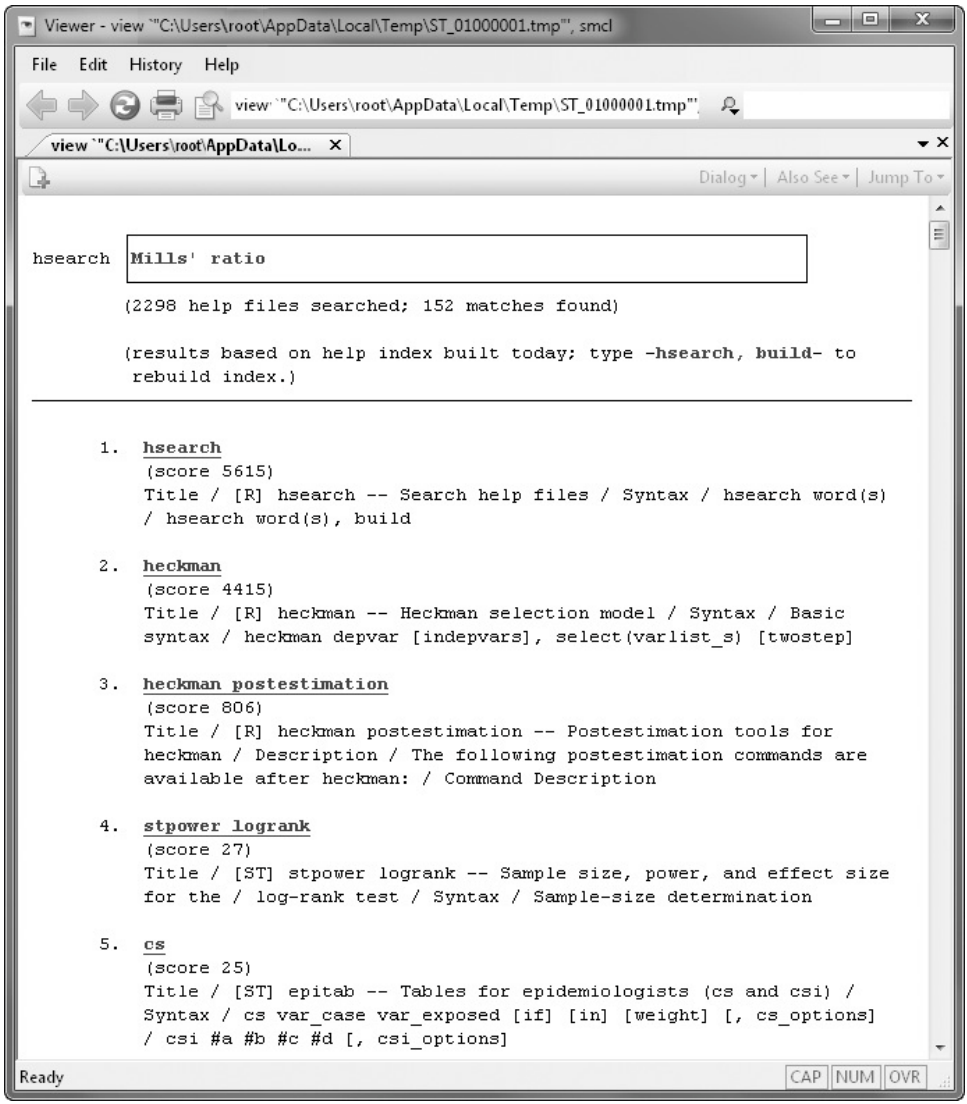
Remarks are presented under the following headings:

Using hsearch
Alternatives to hsearch
Recommendations
How hsearch works

Using hsearch

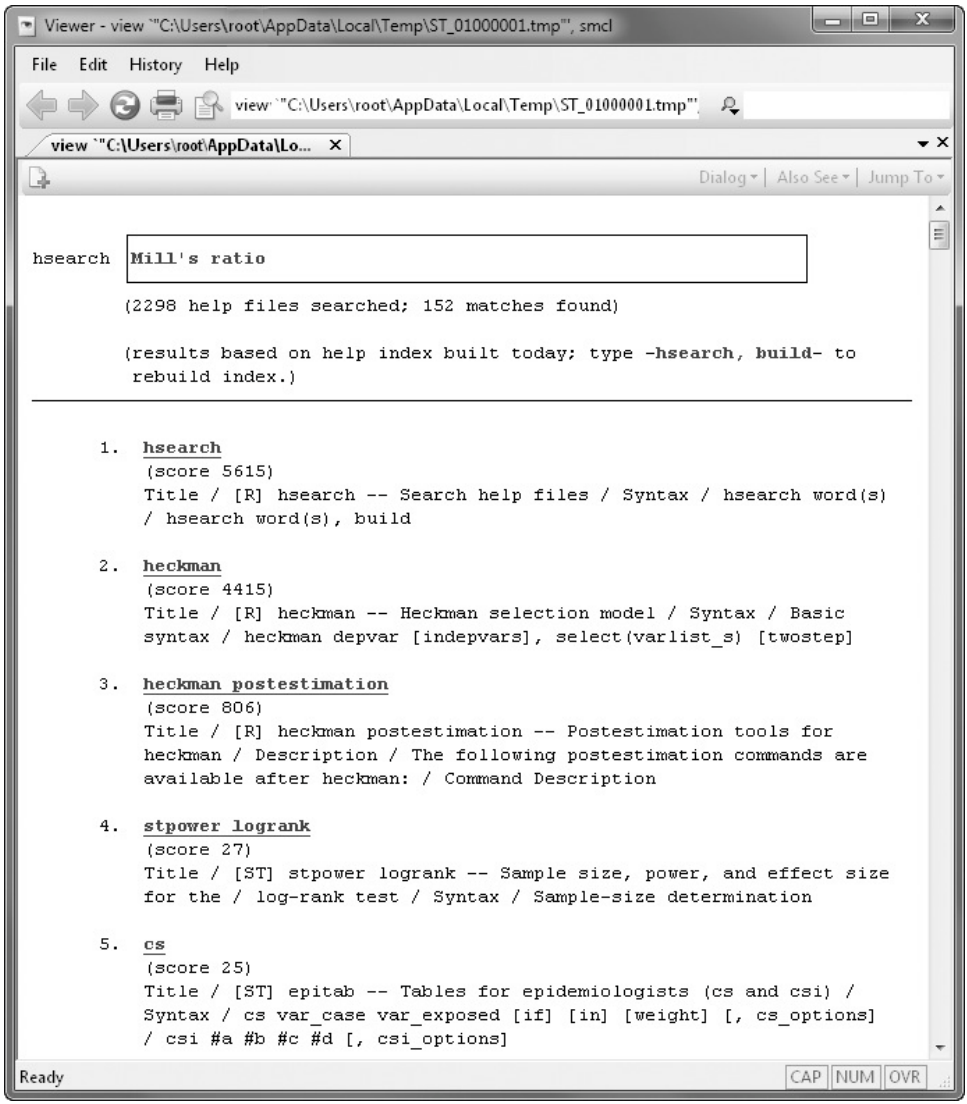
You use `hsearch` to find help for commands and features installed on your computer. If you wanted to find commands related to Mills' ratio, you would type

```
. hsearch Mills' ratio
```



You could just as well type

```
. hsearch Mill's ratio
```



or type any of

```
. hsearch Mills ratio
. hsearch mills ratio
```

or even

```
. hsearch ratio mills
```

because word order, capitalization, and punctuation do not matter.

Alternatives to hsearch

Alternatives to hsearch are search and findit:

```
. search mills ratio
. findit mills ratio
```

search, like hsearch, searches commands already installed on your computer. search searches the keywords; hsearch searches the help files themselves. Hence, hsearch usually finds everything that search finds and more. The fewer things that search finds should be more relevant.

findit searches keywords just as search does, but findit searches the web as well as your computer and so may find commands that you might wish to install.

Recommendations

- In general, hsearch is better than search. hsearch finds more and better organizes the list of what it finds.
- When you know that Stata can do what you are looking for but you cannot remember the command name or when you know that you installed a relevant user-written package, use hsearch.
- When you are unsure whether Stata can do a certain task, use hsearch first and then use findit.

How hsearch works

hsearch searches the .sthlp files.

Finding all those files and then looking through them would take a long time if hsearch did that every time you used it. Instead, hsearch builds an index of the .sthlp files and then searches that.

That file is called sthlpindex.idx and is stored in your PERSONAL directory.

Every so often, hsearch automatically rebuilds the index so that it accurately reflects what is installed on your computer. You can force hsearch to rebuild the index at any time by typing

```
. hsearch, build
```

Methods and formulas

hsearch is implemented as an ado-file.

Title

inequality — Inequality measures

Remarks

Stata does not have commands for inequality measures, except `roctab` has an option to report Gini and Pietra indices; see [R] **roctab**. Stata users, however, have developed an excellent suite of commands, many of which have been published in the *Stata Journal* (SJ) and in the *Stata Technical Bulletin* (STB).

Issue	Insert	Author(s)	Command	Description
STB-48	gr35	N. J. Cox	`psm`, `qsm`, `pdagum`, `qdagum`	Diagnostic plots for assessing Singh–Maddala and Dagum distributions fit by MLE
STB-23	sg31	R. Goldstein	`rspread`	Measures of diversity: Absolute and relative
STB-48	sg104	S. P. Jenkins	`sumdist`, `xfrac`, `ineqdeco`, `geivars`, `ineqfac`, `povdeco`	Analysis of income distributions
STB-48	sg106	S. P. Jenkins	`smfit`, `dagumfit`	Fitting Singh–Maddala and Dagum distributions by maximum likelihood
STB-48	sg107	S. P. Jenkins, P. Van Kerm	`glcurve`	Generalized Lorenz curves and related graphs
STB-49	sg107.1	S. P. Jenkins, P. Van Kerm	`glcurve`	update of sg107
SJ-1-1	gr0001	S. P. Jenkins, P. Van Kerm	`glcurve7`	update for Stata 7 of sg107.1
SJ-7-2	gr0001_3	S. P. Van Kerm, P. Jenkins	`glcurve`	update for Stata 8 of gr0001; *install this version*
STB-48	sg108	P. Van Kerm	`poverty`	Computing poverty indices
STB-51	sg115	D. Jolliffe, B. Krushelnytskyy	`ineqerr`	Bootstrap standard errors for indices of inequality
STB-51	sg117	D. Jolliffe, A. Semykina	`sepov`	Robust standard errors for the Foster–Greer–Thorbecke class of poverty indices
SJ-8-4	st0100_1	A. López-Feldman	`descogini`	Decomposing inequality and obtaining marginal effects
SJ-6-4	snp15_7	R. Newson	`somersd`	Gini coefficient is a special case of Somers' D
STB-23	sg30	E. Whitehouse	`lorenz`, `inequal`, `atkinson`, `relsgini`	Measures of inequality in Stata

More commands may be available; enter Stata and type `search inequality measure, all`.

Max Otto Lorenz (1876–1959) was born in Iowa and studied at the Universities of Iowa and Wisconsin. He proposed what is now known as the Lorenz curve in 1905. Lorenz worked for the Interstate Commerce Commission between 1911 and 1944, mainly with transportation data. His hobbies included calendar reform and Interlingua, a proposed international language.

To download and install the Jenkins and Van Kerm `glcurve` command from the Internet, for instance, you could

1. Select **Help > SJ and User-written Programs**.
2. Click on *Stata Journal*.
3. Click on *sj4-4*.
4. Click on *gr0001_1*.
5. Click on *click here to install*.

or you could instead do the following:

1. Navigate to the appropriate SJ issue:
   a. Type `net from http://www.stata-journal.com/software`
      Type `net cd sj4-4`
   or
   b. Type `net from http://www.stata-journal.com/software/sj4-4`
2. Type `net describe gr0001_1`
3. Type `net install gr0001_1`

To download and install the Jenkins `sumdist` command from the Internet, for instance, you could

1. Select **Help > SJ and User-written Programs**.
2. Click on *STB*.
3. Click on *stb48*.
4. Click on *sg104*.
5. Click on *click here to install*.

or you could instead do the following:

1. Navigate to the appropriate STB issue:
   a. Type `net from http://www.stata.com`
      Type `net cd stb`
      Type `net cd stb48`
   or
   b. Type `net from http://www.stata.com/stb/stb48`
2. Type `net describe sg104`
3. Type `net install sg104`

Title

intreg — Interval regression

Syntax

```
intreg depvar1 depvar2 [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
het(*varlist*[, noconstant])	independent variables to model the variance; use noconstant to suppress constant term
offset(*varname*)	include *varname* in model with coefficient constrained to 1
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, opg, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

indepvars and *varlist* may contain factor variables; see [U] **11.4.3 Factor variables**.

$depvar_1$, $depvar_2$, *indepvars*, and *varlist* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, fracpoly, jackknife, mfp, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

aweights are not allowed with the jackknife prefix; see [R] **jackknife**.

vce() and weights are not allowed with the svy prefix; see [SVY] **svy**.

aweights, fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

coeflegend does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Censored regression > Interval regression

Description

`intreg` fits a model of $y = [\, depvar_1,\ depvar_2 \,]$ on *indepvars*, where y for each observation is point data, interval data, left-censored data, or right-censored data.

$depvar_1$ and $depvar_2$ should have the following form:

Type of data		$depvar_1$	$depvar_2$
point data	$a = [\, a, a \,]$	a	a
interval data	$[\, a, b \,]$	a	b
left-censored data	$(-\infty, b \,]$	.	b
right-censored data	$[\, a, +\infty)$	a	.

Options

Model

`noconstant`; see [R] **estimation options**.

`het(`*varlist* [`, noconstant`]`)` specifies that *varlist* be included in the specification of the conditional variance. This *varlist* enters the variance specification collectively as multiplicative heteroskedasticity.

`offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, [`no`]`log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `intreg` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

`intreg` is a generalization of the models fit by `tobit`. Cameron and Trivedi (2010, 548–550) discuss the differences among censored, truncated, and interval data. If you know that the value for the jth individual is somewhere in the interval $[\,y_{1j},\ y_{2j}\,]$, then the likelihood contribution from this individual is simply $\Pr(y_{1j} \leq Y_j \leq y_{2j})$. For censored data, their likelihoods contain terms of the form $\Pr(Y_j \leq y_j)$ for left-censored data and $\Pr(Y_j \geq y_j)$ for right-censored data, where y_j is the observed censoring value and Y_j denotes the random variable representing the dependent variable in the model.

Hence, `intreg` can fit models for data where each observation represents interval data, left-censored data, right-censored data, or point data. Regardless of the type of observation, the data should be stored in the dataset as interval data; that is, two dependent variables, *depvar*$_1$ and *depvar*$_2$, are used to hold the endpoints of the interval. If the data are left-censored, the lower endpoint is $-\infty$ and is represented by a missing value, '`.`', or an extended missing value, '`.a`, `.b`, ..., `.z`', in *depvar*$_1$. If the data are right-censored, the upper endpoint is $+\infty$ and is represented by a missing value, '`.`' (or an extended missing value), in *depvar*$_2$. Point data are represented by the two endpoints being equal.

Type of data		*depvar*$_1$	*depvar*$_2$
point data	$a = [\,a, a\,]$	a	a
interval data	$[\,a, b\,]$	a	b
left-censored data	$(\,-\infty, b\,]$	.	b
right-censored data	$[\,a, +\infty\,)$	a	.

Truly missing values of the dependent variable must be represented by missing values in both *depvar*$_1$ and *depvar*$_2$.

Interval data arise naturally in many contexts, such as wage data. Often you know only that, for example, a person's salary is between $30,000 and $40,000. Below we give an example for wage data and show how to set up *depvar*$_1$ and *depvar*$_2$.

▷ Example 1

We have a dataset that contains the yearly wages of working women. Women were asked via a questionnaire to indicate a category for their yearly income from employment. The categories were less than 5,000, 5,001–10,000, ..., 25,001–30,000, 30,001–40,000, 40,001–50,000, and more than 50,000. The wage categories are stored in the `wagecat` variable.

```
. use http://www.stata-press.com/data/r12/womenwage
(Wages of women)
. tab wagecat
```

Wage category ($1000s)	Freq.	Percent	Cum.
5	14	2.87	2.87
10	83	17.01	19.88
15	158	32.38	52.25
20	107	21.93	74.18
25	57	11.68	85.86
30	30	6.15	92.01
40	19	3.89	95.90
50	14	2.87	98.77
51	6	1.23	100.00
Total	488	100.00	

A value of 5 for `wagecat` represents the category less than 5,000, a value of 10 represents 5,001 – 10,000, . . . , and a value of 51 represents greater than 50,000.

To use `intreg`, we must create two variables, `wage1` and `wage2`, containing the lower and upper endpoints of the wage categories. Here is one way to do it. We first create a dataset containing the nine wage categories, lag the wage categories into `wage1`, and match-merge this dataset with nine observations back into the main one.

```
. by wagecat: keep if _n==1
(479 observations deleted)
. generate wage1 = wagecat[_n-1]
(1 missing value generated)
. keep wagecat wage1
. save lagwage
file lagwage.dta saved
. use http://www.stata-press.com/data/r12/womenwage
(Wages of women)
. merge m:1 wagecat using lagwage
    Result                           # of obs.
    -----------------------------------------
    not matched                             0
    matched                               488  (_merge==3)
    -----------------------------------------
```

Now we create the upper endpoint and list the new variables:

```
. generate wage2 = wagecat
. replace wage2 = . if wagecat == 51
(6 real changes made, 6 to missing)
. sort age, stable
```

```
. list wage1 wage2 in 1/10
```

	wage1	wage2
1.	.	5
2.	5	10
3.	5	10
4.	10	15
5.	.	5
6.	.	5
7.	.	5
8.	5	10
9.	5	10
10.	5	10

We can now run `intreg`:

```
. intreg wage1 wage2 age c.age#c.age nev_mar rural school tenure
Fitting constant-only model:
Iteration 0:   log likelihood = -967.24956
Iteration 1:   log likelihood =  -967.1368
Iteration 2:   log likelihood =  -967.1368
Fitting full model:
Iteration 0:   log likelihood = -856.65324
Iteration 1:   log likelihood = -856.33294
Iteration 2:   log likelihood = -856.33293
Interval regression                               Number of obs   =        488
                                                  LR chi2(6)      =     221.61
Log likelihood = -856.33293                       Prob > chi2     =     0.0000
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.7914438	.4433604	1.79	0.074	-.0775265	1.660414

We can directly compare the log likelihoods for the `intreg` and `oprobit` models because both likelihoods are discrete. If we had point data in our `intreg` estimation, the likelihood would be a mixture of discrete and continuous terms, and we could not compare it directly with the `oprobit` likelihood.

Here the `oprobit` log likelihood is significantly larger (that is, less negative), so it fits better than the `intreg` model. The `intreg` model assumes normality, but the distribution of wages is skewed and definitely nonnormal. Normality is more closely approximated if we model the log of wages.

```
. generate logwage1 = log(wage1)
(14 missing values generated)
. generate logwage2 = log(wage2)
(6 missing values generated)
. intreg logwage1 logwage2 age c.age#c.age nev_mar rural school tenure
Fitting constant-only model:
Iteration 0:   log likelihood = -889.23647
Iteration 1:   log likelihood = -889.06346
Iteration 2:   log likelihood = -889.06346
Fitting full model:
Iteration 0:   log likelihood = -773.81968
Iteration 1:   log likelihood = -773.36566
Iteration 2:   log likelihood = -773.36563
Interval regression                             Number of obs   =        488
                                                LR chi2(6)      =     231.40
Log likelihood = -773.36563                     Prob > chi2     =     0.0000
```

```

The log likelihood of this `intreg` model is close to the `oprobit` log likelihood, and the z statistics for both models are similar. ◁

❑ Technical note

`intreg` has two parameterizations for the log-likelihood function: the transformed parameterization $(\beta/\sigma,\ 1/\sigma)$ and the untransformed parameterization $(\beta,\ \ln(\sigma))$. By default, the log likelihood for `intreg` is parameterized in the transformed parameter space. This parameterization tends to be more convergent, but it requires that any starting values and constraints have the same parameterization, and it prevents the estimation with multiplicative heteroskedasticity. Therefore, when the `het()` option is specified, `intreg` switches to the untransformed log likelihood for the fit of the conditional-variance model. Similarly, specifying `from()` or `constraints()` causes the optimization in the untransformed parameter space to allow constraints on (and starting values for) the coefficients on the covariates without reference to σ.

The estimation results are all saved in the $(\beta,\ \ln(\sigma))$ metric. ❑

Saved results

intreg saves the following in e():

Scalars

e(N)	number of observations
e(N_unc)	number of uncensored observations
e(N_lc)	number of left-censored observations
e(N_rc)	number of right-censored observations
e(N_int)	number of interval observations
e(k)	number of parameters
e(k_aux)	number of auxiliary parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(ll_c)	log likelihood, comparison model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	p-value for model χ^2 test
e(sigma)	sigma
e(se_sigma)	standard error of sigma
e(rank)	rank of e(V)
e(rank0)	rank of e(V) for constant-only model
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	intreg
e(cmdline)	command as typed
e(depvar)	names of dependent variables
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(het)	heteroskedasticity, if het() specified
e(ml_score)	program used to implement scores
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(footnote)	program and arguments to display footnote
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

`intreg` is implemented as an ado-file.

See Wooldridge (2009, sec. 17.4) or Davidson and MacKinnon (2004, sec. 11.6) for an introduction to censored and truncated regression models.

The likelihood for `intreg` subsumes that of the `tobit` models.

Let $\mathbf{y} = \mathbf{X}\boldsymbol{\beta}+\boldsymbol{\epsilon}$ be the model. $\mathbf{y}$ represents continuous outcomes—either observed or not observed. Our model assumes $\boldsymbol{\epsilon} \sim N(\mathbf{0}, \sigma^2\mathbf{I})$.

For observations $j \in \mathcal{C}$, we observe y_j, that is, point data. Observations $j \in \mathcal{L}$ are left-censored; we know only that the unobserved y_j is less than or equal to $y_{\mathcal{L}j}$, a censoring value that we do know. Similarly, observations $j \in \mathcal{R}$ are right-censored; we know only that the unobserved y_j is greater than or equal to $y_{\mathcal{R}j}$. Observations $j \in \mathcal{I}$ are intervals; we know only that the unobserved y_j is in the interval $[\, y_{1j},\, y_{2j} \,]$.

The log likelihood is

$$
\begin{aligned}
\ln L = &-\frac{1}{2}\sum_{j\in\mathcal{C}} w_j \left\{ \left(\frac{y_j - \mathbf{x}\boldsymbol{\beta}}{\sigma} \right)^2 + \log 2\pi\sigma^2 \right\} \\
&+ \sum_{j\in\mathcal{L}} w_j \log \Phi\left(\frac{y_{\mathcal{L}j} - \mathbf{x}\boldsymbol{\beta}}{\sigma} \right) \\
&+ \sum_{j\in\mathcal{R}} w_j \log \left\{ 1 - \Phi\left(\frac{y_{\mathcal{R}j} - \mathbf{x}\boldsymbol{\beta}}{\sigma} \right) \right\} \\
&+ \sum_{j\in\mathcal{I}} w_j \log \left\{ \Phi\left(\frac{y_{2j} - \mathbf{x}\boldsymbol{\beta}}{\sigma} \right) - \Phi\left(\frac{y_{1j} - \mathbf{x}\boldsymbol{\beta}}{\sigma} \right) \right\}
\end{aligned}
$$

where $\Phi()$ is the standard cumulative normal and w_j is the weight for the jth observation. If no weights are specified, $w_j = 1$. If `aweights` are specified, $w_j = 1$, and σ is replaced by $\sigma/\sqrt{a_j}$ in the above, where a_j are the `aweights` normalized to sum to N.

Maximization is as described in [R] **maximize**; the estimate reported as `_sigma` is $\widehat{\sigma}$.

See Amemiya (1973) for a generalization of the tobit model to variable, but known, cutoffs.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`intreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

intreg postestimation — Postestimation tools for intreg

Description

The following postestimation commands are available after `intreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]

predict [type] {stub* | newvar_reg newvar_lnsigma} [if] [in], scores
```

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the prediction
`stdf`	standard error of the forecast
`pr(`*a*`,`*b*`)`	$\Pr(a < y_j < b)$
`e(`*a*`,`*b*`)`	$E(y_j \mid a < y_j < b)$
`ystar(`*a*`,`*b*`)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` postestimation results.

where a and b may be numbers or variables; a missing ($a \geq .$) means $-\infty$, and b missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated.
a and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(`*varname*`)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial \ln\sigma$.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

ivprobit — Probit model with continuous endogenous regressors

Syntax

Maximum likelihood estimator

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight] [, mle_options]
```

Two-step estimator

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep
    [tse_options]
```

mle_options	Description
Model	
`mle`	use conditional maximum-likelihood estimator; the default
`asis`	retain perfect predictor variables
`constraints(`*constraints*`)`	apply specified linear constraints
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`first`	report first-stage regression
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process
`coeflegend`	display legend instead of statistics

tse_options	Description
Model	
* twostep	use Newey's two-step estimator; the default is mle
asis	retain perfect predictor variables
SE	
vce(*vcetype*)	*vcetype* may be twostep, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
first	report first-stage regression
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
coeflegend	display legend instead of statistics

*twostep is required.

varlist$_1$ and *varlist*$_{\text{iv}}$ may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar, *varlist*$_1$, *varlist*$_2$, and *varlist*$_{\text{iv}}$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
vce(), first, twostep, and weights are not allowed with the svy prefix; see [SVY] **svy**.
fweights, iweights, and pweights are allowed with the maximum likelihood estimator. fweights are allowed with Newey's two-step estimator. See [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Endogenous covariates > Probit model with endogenous covariates

Description

ivprobit fits probit models where one or more of the regressors are endogenously determined. By default, ivprobit uses maximum likelihood estimation. Alternatively, Newey's (1987) minimum chi-squared estimator can be invoked with the twostep option. Both estimators assume that the endogenous regressors are continuous and are not appropriate for use with discrete endogenous regressors. See [R] **ivtobit** for tobit estimation with endogenous regressors and [R] **probit** for probit estimation when the model contains no endogenous regressors.

Options for ML estimator

Model

mle requests that the conditional maximum-likelihood estimator be used. This is the default.

asis requests that all specified variables and observations be retained in the maximization process. This option is typically not used and may introduce numerical instability. Normally, ivprobit drops any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also dropped. For more information, see *Model identification* in [R] **probit**.

`constraints(`*constraints*`)`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. This model's likelihood function can be difficult to maximize, especially with multiple endogenous variables. The `difficult` and `technique(bfgs)` options may be helpful in achieving convergence.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `ivprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Options for two-step estimator

Model

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`asis` requests that all specified variables and observations be retained in the maximization process. This option is typically not used and may introduce numerical instability. Normally, `ivprobit` drops any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also dropped. For more information, see *Model identification* in [R] **probit**.

SE

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `ivprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Model setup
Model identification

Model setup

`ivprobit` fits models with dichotomous dependent variables and endogenous regressors. You can use it to fit a probit model when you suspect that one or more of the regressors are correlated with the error term. `ivprobit` is to probit modeling what `ivregress` is to linear regression analysis; see [R] **ivregress** for more information.

Formally, the model is

$$y_{1i}^* = \boldsymbol{y}_{2i}\boldsymbol{\beta} + \boldsymbol{x}_{1i}\boldsymbol{\gamma} + u_i$$
$$\boldsymbol{y}_{2i} = \boldsymbol{x}_{1i}\boldsymbol{\Pi}_1 + \boldsymbol{x}_{2i}\boldsymbol{\Pi}_2 + \boldsymbol{v}_i$$

where $i = 1, \ldots, N$, $\boldsymbol{y}_{2i}$ is a $1 \times p$ vector of endogenous variables, $\boldsymbol{x}_{1i}$ is a $1 \times k_1$ vector of exogenous variables, $\boldsymbol{x}_{2i}$ is a $1 \times k_2$ vector of additional instruments, and the equation for $\boldsymbol{y}_{2i}$ is written in reduced form. By assumption, $(u_i, \boldsymbol{v}_i) \sim \mathrm{N}(\mathbf{0}, \boldsymbol{\Sigma})$, where σ_{11} is normalized to one to identify the model. $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ are vectors of structural parameters, and $\boldsymbol{\Pi}_1$ and $\boldsymbol{\Pi}_2$ are matrices of reduced-form parameters. This is a recursive model: $\mathbf{y}_{2i}$ appears in the equation for y_{1i}^*, but y_{1i}^* does not appear in the equation for $\mathbf{y}_{2i}$. We do not observe y_{1i}^*; instead, we observe

$$y_{1i} = \begin{cases} 0 & y_{1i}^* < 0 \\ 1 & y_{1i}^* \geq 0 \end{cases}$$

The order condition for identification of the structural parameters requires that $k_2 \geq p$. Presumably, $\boldsymbol{\Sigma}$ is not block diagonal between u_i and $\boldsymbol{v}_i$; otherwise, $\boldsymbol{y}_{2i}$ would not be endogenous.

❑ Technical note

This model is derived under the assumption that $(u_i, \boldsymbol{v}_i)$ is independent and identically distributed multivariate normal for all i. The `vce(cluster` *clustvar*`)` option can be used to control for a lack of independence. As with most probit models, if u_i is heteroskedastic, point estimates will be inconsistent. ❑

Example 1

We have hypothetical data on 500 two-parent households, and we wish to model whether the woman is employed. We have a variable, `fem_work`, that is equal to one if she has a job and zero otherwise. Her decision to work is a function of the number of children at home (`kids`), number of years of schooling completed (`fem_educ`), and other household income measured in thousands of dollars (`other_inc`). We suspect that unobservable shocks affecting the woman's decision to hold a job also affect the household's other income. Therefore, we treat `other_inc` as endogenous. As an instrument, we use the number of years of schooling completed by the man (`male_educ`).

The syntax for specifying the exogenous, endogenous, and instrumental variables is identical to that used in `ivregress`; see [R] **ivregress** for details.

```

Because we did not specify `mle` or `twostep`, `ivprobit` used the maximum likelihood estimator by default. At the top of the output, we see the iteration log. `ivprobit` fits a probit model ignoring endogeneity to obtain starting values for the endogenous model. The header of the output contains the sample size as well as a Wald statistic and p-value for the test of the hypothesis that all the slope coefficients are jointly zero. Below the table of coefficients, Stata reminds us that the endogenous variable is `other_inc` and that `fem_educ`, `kids`, and `male_educ` were used as instruments.

At the bottom of the output is a Wald test of the exogeneity of the instrumented variables. If the test statistic is not significant, there is not sufficient information in the sample to reject the null that there is no endogeneity. Then a regular probit regression may be appropriate; the point estimates

from `ivprobit` are consistent, though those from `probit` (see [R] **probit**) are likely to have smaller standard errors.

◁

Various two-step estimators have also been proposed for the endogenous probit model, and Newey's (1987) minimum chi-squared estimator is available with the `twostep` option.

▷ Example 2

Refitting our labor-supply model with the two-step estimator yields

```
. ivprobit fem_work fem_educ kids (other_inc = male_educ), twostep
Checking reduced-form model...
Two-step probit with endogenous regressors        Number of obs   =        500
                                                  Wald chi2(3)    =      93.97
                                                  Prob > chi2     =     0.0000
------------------------------------------------------------------------------
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   other_inc |   -.058473   .0093364    -6.26   0.000    -.0767719    -.040174
    fem_educ |    .227437   .0281628     8.08   0.000     .1722389     .282635
        kids |  -.1961748   .0496323    -3.95   0.000    -.2934522   -.0988973
       _cons |   .3956061   .4982649     0.79   0.427    -.5809752    1.372187
------------------------------------------------------------------------------
Instrumented:  other_inc
Instruments:   fem_educ kids male_educ
------------------------------------------------------------------------------
Wald test of exogeneity:     chi2(1) =     6.50           Prob > chi2 = 0.0108
```

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity.

◁

❑ Technical note

In a standard probit model, the error term is assumed to have a variance of one. In the probit model with endogenous regressors, we assume that $(u_i, \boldsymbol{v}_i)$ is multivariate normal with covariance matrix

$$\mathrm{Var}(u_i, \boldsymbol{v}_i) = \boldsymbol{\Sigma} = \begin{bmatrix} 1 & \boldsymbol{\Sigma}_{21}' \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

With the properties of the multivariate normal distribution, $\mathrm{Var}(u_i|\boldsymbol{v}_i) = 1 - \boldsymbol{\Sigma}_{21}'\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$. As a result, Newey's estimator and other two-step probit estimators do not yield estimates of $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ but rather $\boldsymbol{\beta}/\sigma$ and $\boldsymbol{\gamma}/\sigma$, where σ is the square root of $\mathrm{Var}(u_i|\boldsymbol{v}_i)$. Hence, we cannot directly compare the estimates obtained from Newey's estimator with those obtained via maximum likelihood or with those obtained from `probit`. See Wooldridge (2010, 585–594) for a discussion of Rivers and Vuong's (1988) two-step estimator. The issues raised pertaining to the interpretation of the coefficients of that estimator are identical to those that arise with Newey's estimator. Wooldridge also discusses ways to obtain marginal effects from two-step estimators.

❑

Despite the coefficients not being directly comparable to their maximum likelihood counterparts, the two-step estimator is nevertheless useful. The maximum likelihood estimator may have difficulty

converging, especially with multiple endogenous variables. The two-step estimator, consisting of nothing more complicated than a probit regression, will almost certainly converge. Moreover, although the coefficients from the two models are not directly comparable, the two-step estimates can still be used to test for statistically significant relationships.

Model identification

As in the linear simultaneous-equation model, the order condition for identification requires that the number of excluded exogenous variables (that is, the additional instruments) be at least as great as the number of included endogenous variables. `ivprobit` checks this for you and issues an error message if the order condition is not met.

Like `probit`, `logit`, and `logistic`, `ivprobit` checks the exogenous and endogenous variables to see if any of them predict the outcome variable perfectly. It will then drop offending variables and observations and fit the model on the remaining data. Instruments that are perfect predictors do not affect estimation, so they are not checked. See *Model identification* in [R] **probit** for more information.

`ivprobit` will also occasionally display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

For an explanation of this message, see [R] **logit**.

Saved results

Methods and formulas

`ivprobit` is implemented as an ado-file.

Fitting limited-dependent variable models with endogenous regressors has received considerable attention in the econometrics literature. Building on the results of Amemiya (1978, 1979), Newey (1987) developed an efficient method of estimation that encompasses both Rivers and Vuong's (1988) simultaneous-equations probit model and Smith and Blundell's (1986) simultaneous-equations tobit model. With modern computers, maximum likelihood estimation is feasible as well. For compactness, we write the model as

$$y_{1i}^{*} = \boldsymbol{z}_i\boldsymbol{\delta} + u_i \tag{1a}$$

$$\boldsymbol{y}_{2i} = \boldsymbol{x}_i\boldsymbol{\Pi} + \boldsymbol{v}_i \tag{1b}$$

where $\boldsymbol{z}_i = (\boldsymbol{y}_{2i}, \boldsymbol{x}_{1i})$, $\boldsymbol{x}_i = (\boldsymbol{x}_{1i}, \boldsymbol{x}_{2i})$, $\boldsymbol{\delta} = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$, and $\boldsymbol{\Pi} = (\boldsymbol{\Pi}_1', \boldsymbol{\Pi}_2')'$.

Deriving the likelihood function is straightforward because we can write the joint density $f\left(y_{1i}, \boldsymbol{y}_{2i}|\boldsymbol{x}_i\right)$ as $f\left(y_{1i}|\boldsymbol{y}_{2i}, \boldsymbol{x}_i\right) f\left(\boldsymbol{y}_{2i}|\boldsymbol{x}_i\right)$. When there is an endogenous regressor, the log likelihood for observation i is

$$\ln L_i = w_i \left[y_{1i} \ln\Phi\left(m_i\right) + \left(1 - y_{1i}\right) \ln\left\{1 - \Phi\left(m_i\right)\right\} + \ln\phi\left(\frac{y_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi}}{\sigma}\right) - \ln\sigma \right]$$

where

$$m_i = \frac{\boldsymbol{z}_i\boldsymbol{\delta} + \rho\left(y_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi}\right)/\sigma}{\left(1 - \rho^2\right)^{\frac{1}{2}}}$$

$\Phi(\cdot)$ and $\phi(\cdot)$ are the standard normal distribution and density functions, respectively; σ is the standard deviation of v_i; ρ is the correlation coefficient between u_i and v_i; and w_i is the weight for observation i or one if no weights were specified. Instead of estimating σ and ρ, we estimate $\ln\sigma$ and $\operatorname{atanh}\rho$, where

$$\operatorname{atanh}\rho = \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right)$$

For multiple endogenous regressors, let

$$\operatorname{Var}(u_i, \boldsymbol{v}_i) = \boldsymbol{\Sigma} = \begin{bmatrix} 1 & \boldsymbol{\Sigma}_{21}' \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

As in any probit model, we have imposed the normalization $\operatorname{Var}(u_i) = 1$ to identify the model. The log likelihood for observation i is

$$\ln L_i = w_i \left[y_{1i} \ln\Phi\left(m_i\right) + \left(1 - y_{1i}\right) \ln\left\{1 - \Phi\left(m_i\right)\right\} + \ln f(\boldsymbol{y}_{2i}|\boldsymbol{x}_i) \right]$$

where

$$\ln f(\boldsymbol{y}_{2i}|\boldsymbol{x}_i) = -\frac{p}{2}\ln 2\pi - \frac{1}{2}\ln\left|\boldsymbol{\Sigma}_{22}\right| - \frac{1}{2}\left(\boldsymbol{y}_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi}\right)\boldsymbol{\Sigma}_{22}^{-1}\left(\boldsymbol{y}_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi}\right)'$$

and

$$m_i = \left(1 - \boldsymbol{\Sigma}_{21}'\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}\right)^{-\frac{1}{2}}\left\{\boldsymbol{z}_i\boldsymbol{\delta} + \left(\boldsymbol{y}_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi}\right)\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}\right\}$$

Instead of maximizing the log-likelihood function with respect to $\boldsymbol{\Sigma}$, we maximize with respect to the Cholesky decomposition $\boldsymbol{S}$ of $\boldsymbol{\Sigma}$; that is, there exists a lower triangular matrix, $\boldsymbol{S}$, such that $\boldsymbol{S}\boldsymbol{S}' = \boldsymbol{\Sigma}$. This maximization ensures that $\boldsymbol{\Sigma}$ is positive definite, as a covariance matrix must be. Let

$$\boldsymbol{S} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ s_{21} & s_{22} & 0 & \dots & 0 \\ s_{31} & s_{32} & s_{33} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ s_{p+1,1} & s_{p+1,2} & s_{p+1,3} & \dots & s_{p+1,p+1} \end{bmatrix}$$

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of `heckman` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

The two-step estimates are obtained using Newey's (1987) minimum chi-squared estimator. The reduced-form equation for y_{1i}^* is

$$\begin{aligned} y_{1i}^* &= (\boldsymbol{x}_i\boldsymbol{\Pi} + \boldsymbol{v}_i)\boldsymbol{\beta} + \boldsymbol{x}_{1i}\boldsymbol{\gamma} + u_i \\ &= \boldsymbol{x}_i\boldsymbol{\alpha} + \boldsymbol{v}_i\boldsymbol{\beta} + u_i \\ &= \boldsymbol{x}_i\boldsymbol{\alpha} + \nu_i \end{aligned}$$

where $\nu_i = \boldsymbol{v}_i\boldsymbol{\beta} + u_i$. Because u_i and $\boldsymbol{v}_i$ are jointly normal, ν_i is also normal. Note that

$$\boldsymbol{\alpha} = \begin{bmatrix} \boldsymbol{\Pi}_1 \\ \boldsymbol{\Pi}_2 \end{bmatrix} \boldsymbol{\beta} + \begin{bmatrix} \boldsymbol{I} \\ \boldsymbol{0} \end{bmatrix} \boldsymbol{\gamma} = D(\boldsymbol{\Pi})\boldsymbol{\delta}$$

where $D(\boldsymbol{\Pi}) = (\boldsymbol{\Pi}, \boldsymbol{I}_1)$ and $\boldsymbol{I}_1$ is defined such that $\boldsymbol{x}_i\boldsymbol{I}_1 = \boldsymbol{x}_{1i}$. Letting $\widehat{\boldsymbol{z}}_i = (\boldsymbol{x}_i\widehat{\boldsymbol{\Pi}}, \boldsymbol{x}_{1i})$, $\widehat{\boldsymbol{z}}_i\boldsymbol{\delta} = \boldsymbol{x}_i D(\widehat{\boldsymbol{\Pi}})\boldsymbol{\delta}$, where $D(\widehat{\boldsymbol{\Pi}}) = (\widehat{\boldsymbol{\Pi}}, \boldsymbol{I}_1)$. Thus one estimator of $\boldsymbol{\alpha}$ is $D(\widehat{\boldsymbol{\Pi}})\boldsymbol{\delta}$; denote this estimator by $\widehat{\boldsymbol{D}}\boldsymbol{\delta}$.

$\boldsymbol{\alpha}$ could also be estimated directly as the solution to

$$\max_{\boldsymbol{\alpha},\boldsymbol{\lambda}} \sum_{i=1}^{N} l(y_{1i}, \boldsymbol{x}_i\boldsymbol{\alpha} + \widehat{\boldsymbol{v}}_i\boldsymbol{\lambda}) \tag{2}$$

where $l(\cdot)$ is the log likelihood for probit. Denote this estimator by $\widetilde{\boldsymbol{\alpha}}$. The inclusion of the $\widehat{\boldsymbol{v}}_i\boldsymbol{\lambda}$ term follows because the multivariate normality of $(u_i, \boldsymbol{v}_i)$ implies that, conditional on $\boldsymbol{y}_{2i}$, the expected value of u_i is nonzero. Because $\boldsymbol{v}_i$ is unobservable, the least-squares residuals from fitting (1*b*) are used.

Amemiya (1978) shows that the estimator of $\boldsymbol{\delta}$ defined by

$$\max_{\boldsymbol{\delta}} \ (\widetilde{\boldsymbol{\alpha}} - \widehat{\boldsymbol{D}}\boldsymbol{\delta})' \widehat{\boldsymbol{\Omega}}^{-1} (\widetilde{\boldsymbol{\alpha}} - \widehat{\boldsymbol{D}}\boldsymbol{\delta})$$

where $\widehat{\boldsymbol{\Omega}}$ is a consistent estimator of the covariance of $\sqrt{N}(\widetilde{\boldsymbol{\alpha}} - \widehat{\boldsymbol{D}}\boldsymbol{\delta})$, is asymptotically efficient relative to all other estimators that minimize the distance between $\widetilde{\boldsymbol{\alpha}}$ and $D(\widehat{\boldsymbol{\Pi}})\boldsymbol{\delta}$. Thus an efficient estimator of $\boldsymbol{\delta}$ is

$$\widehat{\boldsymbol{\delta}} = (\widehat{\boldsymbol{D}}' \widehat{\boldsymbol{\Omega}}^{-1} \widehat{\boldsymbol{D}})^{-1} \widehat{\boldsymbol{D}}' \widehat{\boldsymbol{\Omega}}^{-1} \widetilde{\boldsymbol{\alpha}} \tag{3}$$

and

$$\mathrm{Var}(\widehat{\boldsymbol{\delta}}) = (\widehat{\boldsymbol{D}}' \widehat{\boldsymbol{\Omega}}^{-1} \widehat{\boldsymbol{D}})^{-1} \tag{4}$$

To implement this estimator, we need $\widehat{\boldsymbol{\Omega}}^{-1}$.

Consider the two-step maximum likelihood estimator that results from first fitting (1*b*) by OLS and computing the residuals $\widehat{\boldsymbol{v}}_i = \boldsymbol{y}_{2i} - \boldsymbol{x}_i\widehat{\boldsymbol{\Pi}}$. The estimator is then obtained by solving

$$\max_{\boldsymbol{\delta},\boldsymbol{\lambda}} \sum_{i=1}^{N} l(y_{1i}, \boldsymbol{z}_i\boldsymbol{\delta} + \widehat{\boldsymbol{v}}_i\boldsymbol{\lambda})$$

This is the two-step instrumental variables (2SIV) estimator proposed by Rivers and Vuong (1988), and its role will become apparent shortly.

From Proposition 5 of Newey (1987), $\sqrt{N}(\widetilde{\boldsymbol{\alpha}} - \widehat{\boldsymbol{D}}\boldsymbol{\delta}) \xrightarrow{d} \mathrm{N}(\mathbf{0}, \boldsymbol{\Omega})$, where

$$\boldsymbol{\Omega} = \boldsymbol{J}_{\alpha\alpha}^{-1} + (\boldsymbol{\lambda} - \boldsymbol{\beta})' \boldsymbol{\Sigma}_{22} (\boldsymbol{\lambda} - \boldsymbol{\beta}) \boldsymbol{Q}^{-1}$$

and $\boldsymbol{\Sigma}_{22} = E\{\boldsymbol{v}_i' \boldsymbol{v}_i\}$. $\boldsymbol{J}_{\alpha\alpha}^{-1}$ is simply the covariance matrix of $\widetilde{\boldsymbol{\alpha}}$, ignoring that $\widehat{\boldsymbol{\Pi}}$ is an estimated parameter matrix. Moreover, Newey shows that the covariance matrix from an OLS regression of $\boldsymbol{y}_{2i}(\widehat{\boldsymbol{\lambda}} - \widehat{\boldsymbol{\beta}})$ on $\boldsymbol{x}_i$ is a consistent estimator of the second term. $\widehat{\boldsymbol{\lambda}}$ can be obtained from solving (2), and the 2SIV estimator yields a consistent estimate, $\widehat{\boldsymbol{\beta}}$.

Mechanically, estimation proceeds in several steps.

1. Each of the endogenous right-hand-side variables is regressed on all the exogenous variables, and the fitted values and residuals are calculated. The matrix $\widehat{D} = D(\widehat{\boldsymbol{\Pi}})$ is assembled from the estimated coefficients.
2. `probit` is used to solve (2) and obtain $\widetilde{\boldsymbol{\alpha}}$ and $\widehat{\boldsymbol{\lambda}}$. The portion of the covariance matrix corresponding to $\boldsymbol{\alpha}$, $\boldsymbol{J}_{\alpha\alpha}^{-1}$, is also saved.
3. The 2SIV estimator is evaluated, and the parameters $\widehat{\boldsymbol{\beta}}$ corresponding to $\boldsymbol{y}_{2i}$ are collected.
4. $\boldsymbol{y}_{2i}(\widehat{\boldsymbol{\lambda}} - \widehat{\boldsymbol{\beta}})$ is regressed on $\boldsymbol{x}_i$. The covariance matrix of the parameters from this regression is added to $\boldsymbol{J}_{\alpha\alpha}^{-1}$, yielding $\widehat{\boldsymbol{\Omega}}$.
5. Evaluating (3) and (4) yields the estimates $\widehat{\boldsymbol{\delta}}$ and $\mathrm{Var}(\widehat{\boldsymbol{\delta}})$.
6. A Wald test of the null hypothesis $H_0 : \boldsymbol{\lambda} = \mathbf{0}$, using the 2SIV estimates, serves as our test of exogeneity.

The two-step estimates are not directly comparable to those obtained from the maximum likelihood estimator or from `probit`. The argument is the same for Newey's efficient estimator as for Rivers and Vuong's (1988) 2SIV estimator, so we consider the simpler 2SIV estimator. From the properties of the normal distribution,

$$E(u_i|\boldsymbol{v}_i) = \boldsymbol{v}_i \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21} \qquad \text{and} \qquad \mathrm{Var}(u_i|\boldsymbol{v}_i) = 1 - \boldsymbol{\Sigma}_{21}' \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$$

We write u_i as $u_i = \boldsymbol{v}_i \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21} + e_i = \boldsymbol{v}_i \boldsymbol{\lambda} + e_i$, where $e_i \sim \mathrm{N}(0, 1 - \rho^2)$, $\rho^2 = \boldsymbol{\Sigma}_{21}' \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$, and e_i is independent of $\boldsymbol{v}_i$. In the second stage of 2SIV, we use a probit regression to estimate the parameters of

$$y_{1i} = \boldsymbol{z}_i \boldsymbol{\delta} + \boldsymbol{v}_i \boldsymbol{\lambda} + e_i$$

Because $\boldsymbol{v}_i$ is unobservable, we use the sample residuals from the first-stage regressions.

$$\Pr(y_{1i} = 1|\boldsymbol{z}_i, \boldsymbol{v}_i) = \Pr(\boldsymbol{z}_i \boldsymbol{\delta} + \boldsymbol{v}_i \boldsymbol{\lambda} + e_i > 0|\boldsymbol{z}_i, \boldsymbol{v}_i) = \Phi\left\{(1 - \rho^2)^{-\frac{1}{2}} (\boldsymbol{z}_i \boldsymbol{\delta} + \boldsymbol{v}_i \boldsymbol{\lambda})\right\}$$

Hence, as mentioned previously, 2SIV and Newey's estimator do not estimate $\boldsymbol{\delta}$ and $\boldsymbol{\lambda}$ but rather

$$\boldsymbol{\delta}_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \boldsymbol{\delta} \qquad \text{and} \qquad \boldsymbol{\lambda}_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \boldsymbol{\lambda}$$

Acknowledgments

The two-step estimator is based on the `probitiv` command written by Jonah Gelbach, Department of Economics, Yale University, and the `ivprob` command written by Joe Harkness, Institute of Policy Studies, Johns Hopkins University.

Title

ivprobit postestimation — Postestimation tools for ivprobit

Description

The following postestimation commands are of special interest after `ivprobit`:

Command	Description
`estat classification`	report various summary statistics, including the classification table
`lroc`	compute area under ROC curve and graph the curve
`lsens`	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate after the two-step estimator or the `svy` prefix.

For information about these commands, see [R] **logistic postestimation**.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`[1]	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[2]	likelihood-ratio test; not available with two-step estimator
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`[1]	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `estat ic` and `suest` are not appropriate after `ivprobit, twostep`.

[2] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat (svy)`.

Syntax for predict

After ML or twostep

```
predict [type] newvar [if] [in] [, statistic rules asif]
```

After ML

```
predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
xb	linear prediction; the default
stdp	standard error of the linear prediction
pr	probability of a positive outcome; not available with two-step estimator

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`pr` calculates the probability of a positive outcome. `pr` is not available with the two-step estimator.

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. `rules` is not available with the two-step estimator.

`asif` requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible using the estimated parameters from the model. `asif` is not available with the two-step estimator.

`scores`, not available with `twostep`, calculates equation-level score variables.

For models with one endogenous regressor, four new variables are created.

The first new variable will contain $\partial \ln L/\partial(\boldsymbol{z}_i\boldsymbol{\delta})$.

The second new variable will contain $\partial \ln L/\partial(\boldsymbol{x}_i\boldsymbol{\Pi})$.

The third new variable will contain $\partial \ln L/\partial \operatorname{atanh} \rho$.

The fourth new variable will contain $\partial \ln L/\partial \ln\sigma$.

For models with p endogenous regressors, $p + \{(p+1)(p+2)\}/2$ new variables are created.

The first new variable will contain $\partial \ln L/\partial(\boldsymbol{z}_i\boldsymbol{\delta})$.

The second through $(p+1)$th new variables will contain $\partial \ln L/\partial(\boldsymbol{x}_i\boldsymbol{\Pi}_k)$, $k = 1, \ldots, p$, where $\boldsymbol{\Pi}_k$ is the kth column of $\boldsymbol{\Pi}$.

The remaining score variables will contain the partial derivatives of $\ln L$ with respect to s_{21}, s_{31}, ..., $s_{p+1,1}$, s_{22}, ..., $s_{p+1,2}$, ..., $s_{p+1,p+1}$, where $s_{m,n}$ denotes the (m,n) element of the Cholesky decomposition of the error covariance matrix.

Remarks

Remarks are presented under the following headings:

Marginal effects
Obtaining predicted values

Marginal effects

▷ Example 1

We can obtain marginal effects by using the `margins` command after `ivprobit`. We will calculate average marginal effects by using the labor-supply model of example 1 in [R] **ivprobit**.

```
. use http://www.stata-press.com/data/r12/laborsup
. ivprobit fem_work fem_educ kids (other_inc = male_educ)
  (output omitted)
. margins, dydx(*) predict(pr)
Average marginal effects                        Number of obs   =        500
Model VCE    : OIM
Expression   : Probability of positive outcome, predict(pr)
dy/dx w.r.t. : other_inc fem_educ kids male_educ
```

	dy/dx	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
other_inc	-.014015	.0009836	-14.25	0.000	-.0159428	-.0120872
fem_educ	.0545129	.0066007	8.26	0.000	.0415758	.06745
kids	-.0470199	.0123397	-3.81	0.000	-.0712052	-.0228346
male_educ	0	(omitted)				

Here we see that a \$1,000 increase in `other_inc` leads to an average decrease of 0.014 in the probability that the woman has a job. `male_edu` has no effect because it appears only as an instrument. ◁

Obtaining predicted values

After fitting your model with `ivprobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples by using the `predict` command; see [U] **20 Estimation and postestimation commands** and [R] **predict**. If you had used the maximum likelihood estimator, you could also obtain the probability of a positive outcome.

`predict`'s `pr` option calculates the probability of a positive outcome, remembering any rules used to identify the model, and calculates missing for excluded observations. `predict`'s `rules` option uses the rules in predicting probabilities, whereas `predict`'s `asif` option ignores both the rules and the exclusion criteria and calculates probabilities for all possible observations by using the estimated parameters from the model. See *Obtaining predicted values* in [R] **probit postestimation** for an example.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

The linear prediction is calculated as $\boldsymbol{z}_i\widehat{\boldsymbol{\delta}}$, where $\widehat{\boldsymbol{\delta}}$ is the estimated value of $\boldsymbol{\delta}$, and $\boldsymbol{z}_i$ and $\boldsymbol{\delta}$ are defined in (1*a*) of [R] **ivprobit**. The probability of a positive outcome is $\Phi(\boldsymbol{z}_i\widehat{\boldsymbol{\delta}})$, where $\Phi(\cdot)$ is the standard normal distribution function.

Title

ivregress — Single-equation instrumental-variables regression

Syntax

```
ivregress estimator depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight]
    [, options]
```

estimator	Description
`2sls`	two-stage least squares (2SLS)
`liml`	limited-information maximum likelihood (LIML)
`gmm`	generalized method of moments (GMM)

options	Description
Model	
`noconstant`	suppress constant term
`hascons`	has user-supplied constant
GMM[1]	
`wmatrix(`*wmtype*`)`	*wmtype* may be `robust`, `cluster` *clustvar*, `hac` *kernel*, or `unadjusted`
`center`	center moments in weight matrix computation
`igmm`	use iterative instead of two-step GMM estimator
`eps(#)`[2]	specify # for parameter convergence criterion; default is `eps(1e-6)`
`weps(#)`[2]	specify # for weight matrix convergence criterion; default is `weps(1e-6)`
optimization_options[2]	control the optimization process; seldom used
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `unadjusted`, `robust`, `cluster` *clustvar*, `bootstrap`, `jackknife`, or `hac` *kernel*
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`first`	report first-stage regression
`small`	make degrees-of-freedom adjustments and report small-sample statistics
`noheader`	display only the coefficient table
`depname(`*depname*`)`	substitute dependent variable name
`eform(`*string*`)`	report exponentiated coefficients and use *string* to label them
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
`perfect`	do not check for collinearity between endogenous regressors and excluded instruments
`coeflegend`	display legend instead of statistics

[1]These options may be specified only when gmm is specified.

[2]These options may be specified only when igmm is specified.

varlist$_1$ and *varlist*$_{\text{iv}}$ may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar, *varlist*$_1$, *varlist*$_2$, and *varlist*$_{\text{iv}}$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

aweights are not allowed with the jackknife prefix; see [R] **jackknife**.

hascons, vce(), noheader, depname(), and weights are not allowed with the svy prefix; see [SVY] **svy**.

aweights, fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

perfect and coeflegend do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Endogenous covariates > Single-equation instrumental-variables regression

Description

ivregress fits a linear regression of *depvar* on *varlist*$_1$ and *varlist*$_2$, using *varlist*$_{\text{iv}}$ (along with *varlist*$_1$) as instruments for *varlist*$_2$. ivregress supports estimation via two-stage least squares (2SLS), limited-information maximum likelihood (LIML), and generalized method of moments (GMM).

In the language of instrumental variables, *varlist*$_1$ and *varlist*$_{\text{iv}}$ are the exogenous variables, and *varlist*$_2$ are the endogenous variables.

Options

Model

noconstant; see [R] **estimation options**.

hascons indicates that a user-defined constant or its equivalent is specified among the independent variables.

GMM

wmatrix(*wmtype*) specifies the type of weighting matrix to be used in conjunction with the GMM estimator.

Specifying wmatrix(robust) requests a weighting matrix that is optimal when the error term is heteroskedastic. wmatrix(robust) is the default.

Specifying wmatrix(cluster *clustvar*) requests a weighting matrix that accounts for arbitrary correlation among observations within clusters identified by *clustvar*.

Specifying wmatrix(hac *kernel #*) requests a heteroskedasticity- and autocorrelation-consistent (HAC) weighting matrix using the specified kernel (see below) with # lags. The bandwidth of a kernel is equal to $\#+1$.

Specifying wmatrix(hac *kernel* opt) requests an HAC weighting matrix using the specified kernel, and the lag order is selected using Newey and West's (1994) optimal lag-selection algorithm.

Specifying wmatrix(hac *kernel*) requests an HAC weighting matrix using the specified kernel and $N-2$ lags, where N is the sample size.

There are three kernels available for HAC weighting matrices, and you may request each one by using the name used by statisticians or the name perhaps more familiar to economists:

bartlett or nwest requests the Bartlett (Newey–West) kernel;

parzen or gallant requests the Parzen (Gallant 1987) kernel; and

quadraticspectral or andrews requests the quadratic spectral (Andrews 1991) kernel.

Specifying wmatrix(unadjusted) requests a weighting matrix that is suitable when the errors are homoskedastic. The GMM estimator with this weighting matrix is equivalent to the 2SLS estimator.

center requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

igmm requests that the iterative GMM estimator be used instead of the default two-step GMM estimator. Convergence is declared when the relative change in the parameter vector from one iteration to the next is less than eps() or the relative change in the weight matrix is less than weps().

eps(#) specifies the convergence criterion for successive parameter estimates when the iterative GMM estimator is used. The default is eps(1e-6). Convergence is declared when the relative difference between successive parameter estimates is less than eps() and the relative difference between successive estimates of the weighting matrix is less than weps().

weps(#) specifies the convergence criterion for successive estimates of the weighting matrix when the iterative GMM estimator is used. The default is weps(1e-6). Convergence is declared when the relative difference between successive parameter estimates is less than eps() and the relative difference between successive estimates of the weighting matrix is less than weps().

optimization_options: iterate(#), [no]log. iterate() specifies the maximum number of iterations to perform in conjunction with the iterative GMM estimator. The default is 16,000 or the number set using set maxiter (see [R] **maximize**). log/nolog specifies whether to show the iteration log. These options are seldom used.

SE/Robust

vce(*vcetype*) specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

vce(unadjusted), the default for 2sls and liml, specifies that an unadjusted (nonrobust) VCE matrix be used. The default for gmm is based on the *wmtype* specified in the wmatrix() option; see wmatrix(*wmtype*) above. If wmatrix() is specified with gmm but vce() is not, then *vcetype* is set equal to *wmtype*. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify vce(unadjusted).

ivregress also allows the following:

vce(hac *kernel* [#|opt]) specifies that an HAC covariance matrix be used. The syntax used with vce(hac *kernel* ...) is identical to that used with wmatrix(hac *kernel* ...); see wmatrix(*wmtype*) above.

Reporting

level(#); see [R] **estimation options**.

first requests that the first-stage regression results be displayed.

`small` requests that the degrees-of-freedom adjustment $N/(N-k)$ be made to the variance–covariance matrix of parameters and that small-sample F and t statistics be reported, where N is the sample size and k is the number of parameters estimated. By default, no degrees-of-freedom adjustment is made, and Wald and z statistics are reported. Even with this option, no degrees-of-freedom adjustment is made to the weighting matrix when the GMM estimator is used.

`noheader` suppresses the display of the summary statistics at the top of the output, displaying only the coefficient table.

`depname(`*depname*`)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `depname()` may be specified only at estimation time. *depname* is recorded as the identity of the dependent variable, even though the estimates are calculated using *depvar*. This method affects the labeling of the output—not the results calculated—but could affect later calculations made by `predict`, where the residual would be calculated as deviations from *depname* rather than *depvar*. `depname()` is most typically used when *depvar* is a temporary variable (see [P] **macro**) used as a proxy for *depname*.

`eform(`*string*`)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `eform()` specifies that the coefficient table be displayed in "exponentiated form", as defined in [R] **maximize**, and that *string* be used to label the exponentiated coefficients in the table.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following options are available with `ivregress` but are not shown in the dialog box:

`perfect` requests that `ivregress` not check for collinearity between the endogenous regressors and excluded instruments, allowing one to specify "perfect" instruments. This option cannot be used with the LIML estimator. This option may be required when using `ivregress` to implement other estimators.

`coeflegend`; see [R] **estimation options**.

Remarks

`ivregress` performs instrumental-variables regression and weighted instrumental-variables regression. For a general discussion of instrumental variables, see Baum (2006), Cameron and Trivedi (2005; 2010, chap. 6) Davidson and MacKinnon (1993, 2004), Greene (2012, chap. 8), and Wooldridge (2009, 2010). See Hall (2005) for a lucid presentation of GMM estimation. Angrist and Pischke (2009, chap. 4) offer a casual yet thorough introduction to instrumental-variables estimators, including their use in estimating treatment effects. Some of the earliest work on simultaneous systems can be found in Cowles Commission monographs—Koopmans and Marschak (1950) and Koopmans and Hood (1953)—with the first developments of 2SLS appearing in Theil (1953) and Basmann (1957). However, Stock and Watson (2011, 422–424) present an example of the method of instrumental variables that was first published in 1928 by Philip Wright.

The syntax for `ivregress` assumes that you want to fit one equation from a system of equations or an equation for which you do not want to specify the functional form for the remaining equations of the system. To fit a full system of equations, using either 2SLS equation-by-equation or three-stage least squares, see [R] **reg3**. An advantage of `ivregress` is that you can fit one equation of a multiple-equation system without specifying the functional form of the remaining equations.

Formally, the model fit by `ivregress` is

$$y_i = \mathbf{y}_i\beta_1 + \mathbf{x}_{1i}\beta_2 + u_i \tag{1}$$

$$\mathbf{y}_i = \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i \tag{2}$$

Here y_i is the dependent variable for the ith observation, $\mathbf{y}_i$ represents the endogenous regressors (*varlist*$_2$ in the syntax diagram), $\mathbf{x}_{1i}$ represents the included exogenous regressors (*varlist*$_1$ in the syntax diagram), and $\mathbf{x}_{2i}$ represents the excluded exogenous regressors (*varlist*$_{\text{iv}}$ in the syntax diagram). $\mathbf{x}_{1i}$ and $\mathbf{x}_{2i}$ are collectively called the instruments. u_i and $\mathbf{v}_i$ are zero-mean error terms, and the correlations between u_i and the elements of $\mathbf{v}_i$ are presumably nonzero.

The rest of the discussion is presented under the following headings:

2SLS and LIML estimators
GMM estimator

2SLS and LIML estimators

The most common instrumental-variables estimator is 2SLS.

▷ Example 1: 2SLS estimator

We have state data from the 1980 census on the median dollar value of owner-occupied housing (`hsngval`) and the median monthly gross rent (`rent`). We want to model `rent` as a function of `hsngval` and the percentage of the population living in urban areas (`pcturban`):

$$\texttt{rent}_i = \beta_0 + \beta_1 \texttt{hsngval}_i + \beta_2 \texttt{pcturban}_i + u_i$$

where i indexes states and u_i is an error term.

Because random shocks that affect rental rates in a state probably also affect housing values, we treat `hsngval` as endogenous. We believe that the correlation between `hsngval` and u is not equal to zero. On the other hand, we have no reason to believe that the correlation between `pcturban` and u is nonzero, so we assume that `pcturban` is exogenous.

Because we are treating `hsngval` as an endogenous regressor, we must have one or more additional variables available that are correlated with `hsngval` but uncorrelated with u. Moreover, these excluded exogenous variables must not affect `rent` directly, because if they do then they should be included in the regression equation we specified above. In our dataset, we have a variable for family income (`faminc`) and for region of the country (`region`) that we believe are correlated with `hsngval` but not the error term. Together, `pcturban`, `faminc`, and factor variables `2.region`, `3.region`, and `4.region` constitute our set of instruments.

To fit the equation in Stata, we specify the dependent variable and the list of included exogenous variables. In parentheses, we specify the endogenous regressors, an equal sign, and the excluded exogenous variables. Only the additional exogenous variables must be specified to the right of the equal sign; the exogenous variables that appear in the regression equation are automatically included as instruments.

Here we fit our model with the 2SLS estimator:

```
. use http://www.stata-press.com/data/r12/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
Instrumental variables (2SLS) regression          Number of obs =      50
                                                  Wald chi2(2)  =   90.76
                                                  Prob > chi2   =  0.0000
                                                  R-squared     =  0.5989
                                                  Root MSE      =  22.166
------------------------------------------------------------------------------
        rent |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     hsngval |   .0022398   .0003284     6.82   0.000     .0015961    .0028836
    pcturban |    .081516   .2987652     0.27   0.785     -.504053     .667085
       _cons |   120.7065   15.22839     7.93   0.000     90.85942    150.5536
------------------------------------------------------------------------------
Instrumented:  hsngval
Instruments:   pcturban faminc 2.region 3.region 4.region
```

As we would expect, states with higher housing values have higher rental rates. The proportion of a state's population that is urban does not have a significant effect on rents.

◁

❑ Technical note

In a simultaneous-equations framework, we could write the model we just fit as

$$\texttt{hsngval}_i = \pi_0 + \pi_1\texttt{faminc}_i + \pi_2\texttt{2.region}_i + \pi_3\texttt{3.region}_i + \pi_4\texttt{4.region}_i + v_i$$
$$\texttt{rent}_i = \beta_0 + \beta_1\texttt{hsngval}_i + \beta_2\texttt{pcturban}_i + u_i$$

which here happens to be recursive (triangular), because `hsngval` appears in the equation for `rent` but `rent` does not appear in the equation for `hsngval`. In general, however, systems of simultaneous equations are not recursive. Because this system is recursive, we could fit the two equations individually via OLS if we were willing to assume that u and v were independent. For a more detailed discussion of triangular systems, see Kmenta (1997, 719–720).

Historically, instrumental-variables estimation and systems of simultaneous equations were taught concurrently, and older textbooks describe instrumental-variables estimation solely in the context of simultaneous equations. However, in recent decades, the treatment of endogeneity and instrumental-variables estimation has taken on a much broader scope, while interest in the specification of complete systems of simultaneous equations has waned. Most recent textbooks, such as Cameron and Trivedi (2005), Davidson and MacKinnon (1993, 2004), and Wooldridge (2009, 2010), treat instrumental-variables estimation as an integral part of the modern economists' toolkit and introduce it long before shorter discussions on simultaneous equations.

❑

In addition to the 2SLS member of the κ-class estimators, `ivregress` implements the LIML estimator. Both theoretical and Monte Carlo exercises indicate that the LIML estimator may yield less bias and confidence intervals with better coverage rates than the 2SLS estimator. See Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein) for Monte Carlo evidence.

▷ Example 2: LIML estimator

Here we refit our model with the LIML estimator:

```
. ivregress liml rent pcturban (hsngval = faminc i.region)
Instrumental variables (LIML) regression              Number of obs =      50
                                                      Wald chi2(2)  =   75.71
                                                      Prob > chi2   =  0.0000
                                                      R-squared     =  0.4901
                                                      Root MSE      =  24.992
------------------------------------------------------------------------------
        rent |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     hsngval |   .0026686   .0004173     6.39   0.000     .0018507    .0034865
    pcturban |  -.1827391   .3571132    -0.51   0.609    -.8826681    .5171899
       _cons |   117.6087   17.22625     6.83   0.000     83.84587    151.3715
------------------------------------------------------------------------------
Instrumented:  hsngval
Instruments:   pcturban faminc 2.region 3.region 4.region
```

These results are qualitatively similar to the 2SLS results, although the coefficient on **hsngval** is about 19% higher.

◁

GMM estimator

Since the celebrated paper of Hansen (1982), the GMM has been a popular method of estimation in economics and finance, and it lends itself well to instrumental-variables estimation. The basic principle is that we have some *moment* or *orthogonality* conditions of the form

$$E(\mathbf{z}_i u_i) = \mathbf{0} \tag{3}$$

From (1), we have $u_i = y_i - \mathbf{y}_i\boldsymbol{\beta}_1 - \mathbf{x}_{1i}\boldsymbol{\beta}_2$. What are the elements of the instrument vector $\mathbf{z}_i$? By assumption, $\mathbf{x}_{1i}$ is uncorrelated with u_i, as are the excluded exogenous variables $\mathbf{x}_{2i}$, and so we use $\mathbf{z}_i = [\mathbf{x}_{1i}\ \mathbf{x}_{2i}]$. The moment conditions are simply the mathematical representation of the assumption that the instruments are exogenous—that is, the instruments are orthogonal to (uncorrelated with) u_i.

If the number of elements in $\mathbf{z}_i$ is just equal to the number of unknown parameters, then we can apply the analogy principle to (3) and solve

$$\frac{1}{N}\sum_i \mathbf{z}_i u_i = \frac{1}{N}\sum_i \mathbf{z}_i\left(y_i - \mathbf{y}_i\boldsymbol{\beta}_1 - \mathbf{x}_{1i}\boldsymbol{\beta}_2\right) = \mathbf{0} \tag{4}$$

This equation is known as the method of moments estimator. Here where the number of instruments equals the number of parameters, the method of moments estimator coincides with the 2SLS estimator, which also coincides with what has historically been called the indirect least-squares estimator (Judge et al. 1985, 595).

The "generalized" in GMM addresses the case in which the number of instruments (columns of $\mathbf{z}_i$) exceeds the number of parameters to be estimated. Here there is no unique solution to the population moment conditions defined in (3), so we cannot use (4). Instead, we define the objective function

$$Q(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2) = \left(\frac{1}{N}\sum_i \mathbf{z}_i u_i\right)' \mathbf{W} \left(\frac{1}{N}\sum_i \mathbf{z}_i u_i\right) \tag{5}$$

where $\mathbf{W}$ is a positive-definite matrix with the same number of rows and columns as the number of columns of $\mathbf{z}_i$. $\mathbf{W}$ is known as the weighting matrix, and we specify its structure with the `wmatrix()` option. The GMM estimator of (β_1, β_2) minimizes $Q(\beta_1, \beta_2)$; that is, the GMM estimator chooses β_1 and β_2 to make the moment conditions as close to zero as possible for a given $\mathbf{W}$. For a more general GMM estimator, see [R] **gmm**. `gmm` does not restrict you to fitting a single linear equation, though the syntax is more complex.

A well-known result is that if we define the matrix $\mathbf{S}_0$ to be the covariance of $\mathbf{z}_i u_i$ and set $\mathbf{W} = \mathbf{S}_0^{-1}$, then we obtain the optimal two-step GMM estimator, where by optimal estimator we mean the one that results in the smallest variance given the moment conditions defined in (3).

Suppose that the errors u_i are heteroskedastic but independent among observations. Then

$$\mathbf{S}_0 = E(\mathbf{z}_i u_i u_i \mathbf{z}_i') = E(u_i^2 \mathbf{z}_i \mathbf{z}_i')$$

and the sample analogue is

$$\widehat{\mathbf{S}} = \frac{1}{N} \sum_i \widehat{u}_i^2 \mathbf{z}_i \mathbf{z}_i' \tag{6}$$

To implement this estimator, we need estimates of the sample residuals $\widehat{u}_i$. `ivregress gmm` obtains the residuals by estimating β_1 and β_2 by 2SLS and then evaluates (6) and sets $\mathbf{W} = \widehat{\mathbf{S}}^{-1}$. Equation (6) is the same as the center term of the "sandwich" robust covariance matrix available from most Stata estimation commands through the `vce(robust)` option.

▷ Example 3: GMM estimator

Here we refit our model of rents by using the GMM estimator, allowing for heteroskedasticity in u_i:

```
. ivregress gmm rent pcturban (hsngval = faminc i.region), wmatrix(robust)
Instrumental variables (GMM) regression               Number of obs =      50
                                                      Wald chi2(2)  =  112.09
                                                      Prob > chi2   =  0.0000
                                                      R-squared     =  0.6616
GMM weight matrix: Robust                             Root MSE      =  20.358

------------------------------------------------------------------------------
             |               Robust
        rent |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     hsngval |   .0014643   .0004473     3.27   0.001     .0005877    .002341
    pcturban |   .7615482   .2895105     2.63   0.009     .1941181    1.328978
       _cons |   112.1227   10.80234    10.38   0.000     90.95052    133.2949
------------------------------------------------------------------------------
Instrumented:  hsngval
Instruments:   pcturban faminc 2.region 3.region 4.region
```

Because we requested that a heteroskedasticity-consistent weighting matrix be used during estimation but did not specify the `vce()` option, `ivregress` reported standard errors that are robust to heteroskedasticity. Had we specified `vce(unadjusted)`, we would have obtained standard errors that would be correct only if the weighting matrix $\mathbf{W}$ does in fact converge to $\mathbf{S}_0^{-1}$.

◁

❑ Technical note

Many software packages that implement GMM estimation use the same heteroskedasticity-consistent weighting matrix we used in the previous example to obtain the optimal two-step estimates but do not use a heteroskedasticity-consistent VCE, even though they may label the standard errors as being "robust". To replicate results obtained from other packages, you may have to use the `vce(unadjusted)` option. See *Methods and formulas* below for a discussion of robust covariance matrix estimation in the GMM framework.

❑

By changing our definition of $\mathbf{S}_0$, we can obtain GMM estimators suitable for use with other types of data that violate the assumption that the errors are independent and identically distributed. For example, you may have a dataset that consists of multiple observations for each person in a sample. The observations that correspond to the same person are likely to be correlated, and the estimation technique should account for that lack of independence. Say that in your dataset, people are identified by the variable `personid` and you type

```
. ivregress gmm ..., wmatrix(cluster personid)
```

Here `ivregress` estimates $\mathbf{S}_0$ as

$$\widehat{\mathbf{S}} = \frac{1}{N}\sum_{c\in C}\mathbf{q}_c\mathbf{q}_c'$$

where C denotes the set of clusters and

$$\mathbf{q}_c = \sum_{i\in c_j}\widehat{u}_i\mathbf{z}_i$$

where c_j denotes the jth cluster. This weighting matrix accounts for the within-person correlation among observations, so the GMM estimator that uses this version of $\mathbf{S}_0$ will be more efficient than the estimator that ignores this correlation.

▷ Example 4: GMM estimator with clustering

We have data from the National Longitudinal Survey on young women's wages as reported in a series of interviews from 1968 through 1988, and we want to fit a model of wages as a function of each woman's age and age squared, job tenure, birth year, and level of education. We believe that random shocks that affect a woman's wage also affect her job tenure, so we treat tenure as endogenous. As additional instruments, we use her union status, number of weeks worked in the past year, and a dummy indicating whether she lives in a metropolitan area. Because we have several observations for each woman (corresponding to interviews done over several years), we want to control for clustering on each person.

```
. use http://www.stata-press.com/data/r12/nlswork
(National Longitudinal Survey.  Young Women 14-26 years of age in 1968)
. ivregress gmm ln_wage age c.age#c.age birth_yr grade
> (tenure = union wks_work msp), wmatrix(cluster idcode)
Instrumental variables (GMM) regression               Number of obs =   18625
                                                      Wald chi2(5)  = 1807.17
                                                      Prob > chi2   =  0.0000
                                                      R-squared     =       .
GMM weight matrix: Cluster (idcode)                   Root MSE      =  .46951
                             (Std. Err. adjusted for 4110 clusters in idcode)
------------------------------------------------------------------------------
             |               Robust

------------------------------------------------------------------------------
Instrumented:  tenure
Instruments:   age c.age#c.age birth_yr grade union wks_work msp
```

Both job tenure and years of schooling have significant positive effects on wages.

◁

Time-series data are often plagued by serial correlation. In these cases, we can construct a weighting matrix to account for the fact that the error in period t is probably correlated with the errors in periods $t-1$, $t-2$, etc. An HAC weighting matrix can be used to account for both serial correlation and potential heteroskedasticity.

To request an HAC weighting matrix, you specify the `wmatrix(hac` *kernel* $\left[\,\#\,|\,$`opt`$\,\right]$`)` option. *kernel* specifies which of three kernels to use: `bartlett`, `parzen`, or `quadraticspectral`. *kernel* determines the amount of weight given to lagged values when computing the HAC matrix, and # denotes the maximum number of lags to use. Many texts refer to the bandwidth of the kernel instead of the number of lags; the bandwidth is equal to the number of lags plus one. If neither `opt` nor # is specified, then $N-2$ lags are used, where N is the sample size.

If you specify `wmatrix(hac` *kernel* `opt)`, then `ivregress` uses Newey and West's (1994) algorithm for automatically selecting the number of lags to use. Although the authors' Monte Carlo simulations do show that the procedure may result in size distortions of hypothesis tests, the procedure is still useful when little other information is available to help choose the number of lags.

For more on GMM estimation, see Baum (2006); Baum, Schaffer, and Stillman (2003, 2007); Cameron and Trivedi (2005); Davidson and MacKinnon (1993, 2004); Hayashi (2000); or Wooldridge (2010). See Newey and West (1987) for an introduction to HAC covariance matrix estimation.

Saved results

ivregress saves the following in e():

Scalars

e(N)	number of observations
e(mss)	model sum of squares
e(df_m)	model degrees of freedom
e(rss)	residual sum of squares
e(df_r)	residual degrees of freedom
e(r2)	R^2
e(r2_a)	adjusted R^2
e(F)	F statistic
e(rmse)	root mean squared error
e(N_clust)	number of clusters
e(chi2)	χ^2
e(kappa)	κ used in LIML estimator
e(J)	value of GMM objective function
e(wlagopt)	lags used in HAC weight matrix (if Newey–West algorithm used)
e(vcelagopt)	lags used in HAC VCE matrix (if Newey–West algorithm used)
e(rank)	rank of e(V)
e(iterations)	number of GMM iterations (0 if not applicable)

Macros

Methods and formulas

ivregress is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Notation
2SLS and LIML estimators
GMM estimator

Notation

Items printed in lowercase and italicized (for example, x) are scalars. Items printed in lowercase and boldfaced (for example, $\mathbf{x}$) are vectors. Items printed in uppercase and boldfaced (for example, $\mathbf{X}$) are matrices.

The model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\Pi}_1 + \mathbf{X}_2\boldsymbol{\Pi}_2 + \mathbf{v} = \mathbf{Z}\boldsymbol{\Pi} + \mathbf{V}$$

where $\mathbf{y}$ is an $N \times 1$ vector of the left-hand-side variable; N is the sample size; $\mathbf{Y}$ is an $N \times p$ matrix of p endogenous regressors; $\mathbf{X}_1$ is an $N \times k_1$ matrix of k_1 included exogenous regressors; $\mathbf{X}_2$ is an $N \times k_2$ matrix of k_2 excluded exogenous variables, $\mathbf{X} = [\mathbf{Y}\ \mathbf{X}_1]$, $\mathbf{Z} = [\mathbf{X}_1\ \mathbf{X}_2]$; $\mathbf{u}$ is an $N \times 1$ vector of errors; $\mathbf{V}$ is an $N \times p$ matrix of errors; $\boldsymbol{\beta} = [\boldsymbol{\beta}_1\ \boldsymbol{\beta}_2]$ is a $k = (p + k_1) \times 1$ vector of parameters; and $\boldsymbol{\Pi}$ is a $(k_1 + k_2) \times p$ vector of parameters. If a constant term is included in the model, then one column of $\mathbf{X}_1$ contains all ones.

Let $\mathbf{v}$ be a column vector of weights specified by the user. If no weights are specified, $\mathbf{v} = \mathbf{1}$. Let $\mathbf{w}$ be a column vector of normalized weights. If no weights are specified or if the user specified fweights or iweights, $\mathbf{w} = \mathbf{v}$; otherwise, $\mathbf{w} = \{\mathbf{v}/(\mathbf{1}'\mathbf{v})\}(\mathbf{1}'\mathbf{1})$. Let $\mathbf{D}$ denote the $N \times N$ matrix with $\mathbf{w}$ on the main diagonal and zeros elsewhere. If no weights are specified, $\mathbf{D}$ is the identity matrix.

The weighted number of observations n is defined as $\mathbf{1}'\mathbf{w}$. For iweights, this is truncated to an integer. The *sum of the weights* is $\mathbf{1}'\mathbf{v}$. Define $c = 1$ if there is a constant in the regression and zero otherwise.

The order condition for identification requires that $k_2 \geq p$: the number of excluded exogenous variables must be at least as great as the number of endogenous regressors.

In the following formulas, if weights are specified, $\mathbf{X}_1'\mathbf{X}_1$, $\mathbf{X}'\mathbf{X}$, $\mathbf{X}'\mathbf{y}$, $\mathbf{y}'\mathbf{y}$, $\mathbf{Z}'\mathbf{Z}$, $\mathbf{Z}'\mathbf{X}$, and $\mathbf{Z}'\mathbf{y}$ are replaced with $\mathbf{X}_1'\mathbf{D}\mathbf{X}_1$, $\mathbf{X}'\mathbf{D}\mathbf{X}$, $\mathbf{X}'\mathbf{D}\mathbf{y}$, $\mathbf{y}'\mathbf{D}\mathbf{y}$, $\mathbf{Z}'\mathbf{D}\mathbf{Z}$, $\mathbf{Z}'\mathbf{D}\mathbf{X}$, and $\mathbf{Z}'\mathbf{D}\mathbf{y}$, respectively. We suppress the $\mathbf{D}$ below to simplify the notation.

2SLS and LIML estimators

Define the κ-class estimator of β as

$$\mathbf{b} = \left\{\mathbf{X}'(\mathbf{I}-\kappa\mathbf{M}_\mathbf{Z})^{-1}\mathbf{X}\right\}^{-1}\mathbf{X}'(\mathbf{I}-\kappa\mathbf{M}_\mathbf{Z})^{-1}\mathbf{y}$$

where $\mathbf{M}_\mathbf{Z} = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$. The 2SLS estimator results from setting $\kappa = 1$. The LIML estimator results from selecting κ to be the minimum eigenvalue of $(\mathbf{Y}'\mathbf{M}_\mathbf{Z}\mathbf{Y})^{-1/2}\mathbf{Y}'\mathbf{M}_{\mathbf{X}_1}\mathbf{Y}(\mathbf{Y}'\mathbf{M}_\mathbf{Z}\mathbf{Y})^{-1/2}$, where $\mathbf{M}_{\mathbf{X}_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'$.

The total sum of squares (TSS) equals $\mathbf{y}'\mathbf{y}$ if there is no intercept and $\mathbf{y}'\mathbf{y} - \left\{(\mathbf{1}'\mathbf{y})^2/n\right\}$ otherwise. The degrees of freedom are $n-c$. The error sum of squares (ESS) is defined as $\mathbf{y}'\mathbf{y} - 2\mathbf{b}\mathbf{X}'\mathbf{y} + \mathbf{b}'\mathbf{X}'\mathbf{X}\mathbf{b}$. The model sum of squares (MSS) equals TSS − ESS. The degrees of freedom are $k-c$.

The mean squared error, s^2, is defined as ESS$/(n-k)$ if `small` is specified and ESS$/n$ otherwise. The root mean squared error is s, its square root.

If $c = 1$ and `small` is not specified, a Wald statistic, W, of the joint significance of the $k-1$ parameters of β except the constant term is calculated; $W \sim \chi^2(k-1)$. If $c = 1$ and `small` is specified, then an F statistic is calculated as $F = W/(k-1)$; $F \sim F(k-1, n-k)$.

The R-squared is defined as $R^2 = 1 - \text{ESS}/\text{TSS}$.

The adjusted R-squared is $R^2_\text{a} = 1 - (1-R^2)(n-c)/(n-k)$.

If `robust` is not specified, then $\text{Var}(\mathbf{b}) = s^2\left\{\mathbf{X}'(\mathbf{I}-\kappa\mathbf{M}_\mathbf{Z})^{-1}\mathbf{X}\right\}^{-1}$. For a discussion of robust variance estimates in regression and regression with instrumental variables, see *Methods and formulas* in [R] **regress**. If `small` is not specified, then $k = 0$ in the formulas given there.

This command also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

GMM estimator

We obtain an initial consistent estimate of β by using the 2SLS estimator; see above. Using this estimate of β, we compute the weighting matrix $\mathbf{W}$ and calculate the GMM estimator

$$\mathbf{b}_\text{GMM} = \left\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\right\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{y}$$

The variance of $\mathbf{b}_\text{GMM}$ is

$$\text{Var}(\mathbf{b}_\text{GMM}) = n\left\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\right\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\widehat{\mathbf{S}}\mathbf{W}\mathbf{Z}'\mathbf{X}\left\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\right\}^{-1}$$

$\text{Var}(\mathbf{b}_\text{GMM})$ is of the sandwich form $\mathbf{DMD}$; see [P] **_robust**. If the user specifies the `small` option, `ivregress` implements a small-sample adjustment by multiplying the VCE by $N/(N-k)$.

If `vce(unadjusted)` is specified, then we set $\widehat{\mathbf{S}} = \mathbf{W}^{-1}$ and the VCE reduces to the "optimal" GMM variance estimator

$$\text{Var}(\beta_\text{GMM}) = n\left\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\right\}^{-1}$$

However, if $\mathbf{W}^{-1}$ is not a good estimator of $E(\mathbf{z}_i u_i u_i \mathbf{z}_i')$, then the optimal GMM estimator is inefficient, and inference based on the optimal variance estimator could be misleading.

$\mathbf{W}$ is calculated using the residuals from the initial 2SLS estimates, whereas $\mathbf{S}$ is estimated using the residuals based on $\mathbf{b}_{\mathrm{GMM}}$. The `wmatrix()` option affects the form of $\mathbf{W}$, whereas the `vce()` option affects the form of $\mathbf{S}$. Except for different residuals being used, the formulas for $\mathbf{W}^{-1}$ and $\mathbf{S}$ are identical, so we focus on estimating $\mathbf{W}^{-1}$.

If `wmatrix(unadjusted)` is specified, then

$$\mathbf{W}^{-1} = \frac{s^2}{n}\sum_i \mathbf{z}_i\mathbf{z}_i'$$

where $s^2 = \sum_i u_i^2/n$. This weight matrix is appropriate if the errors are homoskedastic.

If `wmatrix(robust)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n}\sum_i u_i^2\mathbf{z}_i\mathbf{z}_i'$$

which is appropriate if the errors are heteroskedastic.

If `wmatrix(cluster` *clustvar*`)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n}\sum_c \mathbf{q}_c\mathbf{q}_c'$$

where c indexes clusters,

$$\mathbf{q}_c = \sum_{i\in c_j} u_i\mathbf{z}_i$$

and c_j denotes the jth cluster.

If `wmatrix(hac` *kernel* `[#])` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n}\sum_i u_i^2\mathbf{z}_i\mathbf{z}_i' + \frac{1}{n}\sum_{l=1}^{l=n-1}\sum_{i=l+1}^{i=n} K(l,m)u_iu_{i-l}\left(\mathbf{z}_i\mathbf{z}_{i-l}' + \mathbf{z}_{i-l}\mathbf{z}_i'\right)$$

where $m = \#$ if # is specified and $m = n-2$ otherwise. Define $z = l/(m+1)$. If *kernel* is `nwest`, then

$$K(l,m) = \begin{cases} 1-z & 0 \le z \le 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `gallant`, then

$$K(l,m) = \begin{cases} 1-6z^2+6z^3 & 0 \le z \le 0.5 \\ 2(1-z)^3 & 0.5 < z \le 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `quadraticspectral`, then

$$K(l,m) = \begin{cases} 1 & z = 0 \\ 3\left\{\sin(\theta)/\theta - \cos(\theta)\right\}/\theta^2 & \text{otherwise} \end{cases}$$

where $\theta = 6\pi z/5$.

If `wmatrix(hac` *kernel* `opt)` is specified, then `ivregress` uses Newey and West's (1994) automatic lag-selection algorithm, which proceeds as follows. Define $\mathbf{h}$ to be a $(k_1+k_2)\times 1$ vector containing ones in all rows except for the row corresponding to the constant term (if present); that row contains a zero. Define

$$f_i = (u_i \mathbf{z}_i)\mathbf{h}$$

$$\widehat{\sigma}_j = \frac{1}{n}\sum_{i=j+1}^{n} f_i f_{i-j} \qquad j = 0, \ldots, m^*$$

$$\widehat{s}^{(q)} = 2\sum_{j=1}^{m^*} \widehat{\sigma}_j j^q$$

$$\widehat{s}^{(0)} = \widehat{\sigma}_0 + 2\sum_{j=1}^{m^*} \widehat{\sigma}_j$$

$$\widehat{\gamma} = c_\gamma \left\{ \left(\frac{\widehat{s}^{(q)}}{\widehat{s}^{(0)}} \right)^2 \right\}^{1/2q+1}$$

$$m = \widehat{\gamma} n^{1/(2q+1)}$$

where q, m^*, and c_γ depend on the kernel specified:

Kernel	q	m^*	c_γ
Bartlett	1	int $\{20(T/100)^{2/9}\}$	1.1447
Parzen	2	int $\{20(T/100)^{4/25}\}$	2.6614
Quadratic spectral	2	int $\{20(T/100)^{2/25}\}$	1.3221

where int(x) denotes the integer obtained by truncating x toward zero. For the Bartlett and Parzen kernels, the optimal lag is min$\{$int$(m), m^*\}$. For the quadratic spectral, the optimal lag is min$\{m, m^*\}$.

If `center` is specified, when computing weighting matrices `ivregress` replaces the term $u_i z_i$ in the formulas above with $u_i \mathbf{z}_i - \overline{u\mathbf{z}}$, where $\overline{u\mathbf{z}} = \sum_i u_i \mathbf{z}_i / N$.

Title

ivregress postestimation — Postestimation tools for ivregress

Description

The following postestimation commands are of special interest after `ivregress`:

Command	Description
`estat endogenous`	perform tests of endogeneity
`estat firststage`	report "first-stage" regression statistics
`estat overid`	perform tests of overidentifying restrictions

These commands are not appropriate after the `svy` prefix.

For information about these commands, see below.

The following postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	VCE and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Special-interest postestimation commands

`estat endogenous` performs tests to determine whether endogenous regressors in the model are in fact exogenous. After GMM estimation, the C (difference-in-Sargan) statistic is reported. After 2SLS estimation with an unadjusted VCE, the Durbin (1954) and Wu–Hausman (Wu 1974; Hausman 1978) statistics are reported. After 2SLS estimation with a robust VCE, Wooldridge's (1995) robust score test and a robust regression-based test are reported. In all cases, if the test statistic is significant, then the variables being tested must be treated as endogenous. `estat endogenous` is not available after LIML estimation.

`estat firststage` reports various statistics that measure the relevance of the excluded exogenous variables. By default, whether the equation has one or more than one endogenous regressor determines what statistics are reported.

`estat overid` performs tests of overidentifying restrictions. If the 2SLS estimator was used, Sargan's (1958) and Basmann's (1960) χ^2 tests are reported, as is Wooldridge's (1995) robust score test; if the LIML estimator was used, Anderson and Rubin's (1950) χ^2 test and Basmann's F test are reported; and if the GMM estimator was used, Hansen's (1982) J statistic χ^2 test is reported. A statistically significant test statistic always indicates that the instruments may not be valid.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]

predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
`xb`	linear prediction; the default
`residuals`	residuals
`stdp`	standard error of the prediction
`stdf`	standard error of the forecast
`pr(a,b)`	$\Pr(a < y_j < b)$
`e(a,b)`	$E(y_j \mid a < y_j < b)$
`ystar(a,b)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where a and b may be numbers or variables; a missing ($a \geq .$) means $-\infty$, and b missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, that is, $y_j - \mathbf{x}_j\mathbf{b}$. These are based on the estimated equation when the observed values of the endogenous variables are used—not the projections of the instruments onto the endogenous variables.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. This is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated.
a and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`scores` calculates the scores for the model. A new score variable is created for each endogenous regressor, as well as an equation-level score that applies to all exogenous variables and constant term (if present).

Syntax for estat endogenous

```
estat endogenous [ varlist ] [ , lags(#) forceweights forcenonrobust ]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat endogenous

`lags(#)` specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of endogeneity. Specifying `lags(0)` requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is `lags(1)`.

`forceweights` requests that the tests of endogeneity be computed even though `aweights`, `pweights`, or `iweights` were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

forcenonrobust requests that the Durbin and Wu–Hausman tests be performed after 2SLS estimation even though a robust VCE was used at estimation time. This option is available only if the model was fit by 2SLS.

Syntax for estat firststage

```
estat firststage [, all forcenonrobust]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat firststage

all requests that all first-stage goodness-of-fit statistics be reported regardless of whether the model contains one or more endogenous regressors. By default, if the model contains one endogenous regressor, then the first-stage R^2, adjusted R^2, partial R^2, and F statistics are reported, whereas if the model contains multiple endogenous regressors, then Shea's partial R^2 and adjusted partial R^2 are reported instead.

forcenonrobust requests that the minimum eigenvalue statistic and its critical values be reported even though a robust VCE was used at estimation time. The reported critical values assume that the errors are independent and identically distributed (i.i.d.) normal, so the user must determine whether the critical values are appropriate for a given application.

Syntax for estat overid

```
estat overid [, lags(#) forceweights forcenonrobust]
```

Menu

Statistics > Postestimation > Reports and statistics

Options for estat overid

lags(#) specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of overidentifying restrictions. Specifying lags(0) requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is lags(1).

forceweights requests that the tests of overidentifying restrictions be computed even though aweights, pweights, or iweights were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

`forcenonrobust` requests that the Sargan and Basmann tests of overidentifying restrictions be performed after 2SLS or LIML estimation even though a robust VCE was used at estimation time. These tests assume that the errors are i.i.d. normal, so the user must determine whether the critical values are appropriate for a given application.

Remarks

Remarks are presented under the following headings:

estat endogenous
estat firststage
estat overid

estat endogenous

A natural question to ask is whether a variable presumed to be endogenous in the previously fit model could instead be treated as exogenous. If the endogenous regressors are in fact exogenous, then the OLS estimator is more efficient; and depending on the strength of the instruments and other factors, the sacrifice in efficiency by using an instrumental-variables estimator can be significant. Thus, unless an instrumental-variables estimator is really needed, OLS should be used instead. `estat endogenous` provides several tests of endogeneity after 2SLS and GMM estimation.

▷ Example 1

In example 1 of [R] **ivregress**, we fit a model of the average rental rate for housing in a state as a function of the percentage of the population living in urban areas and the average value of houses. We treated `hsngval` as endogenous because unanticipated shocks that affect rental rates probably affect house prices as well. We used family income and region dummies as additional instruments for `hsngval`. Here we test whether we could treat `hsngval` as exogenous.

```
. use http://www.stata-press.com/data/r12/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
  (output omitted)
. estat endogenous

  Tests of endogeneity
  Ho: variables are exogenous

  Durbin (score) chi2(1)          =  12.8473  (p = 0.0003)
  Wu-Hausman F(1,46)              =  15.9067  (p = 0.0002)
```

Because we did not specify any variable names after the `estat endogenous` command, Stata by default tested all the endogenous regressors (namely, `hsngval`) in our model. The null hypothesis of the Durbin and Wu–Hausman tests is that the variable under consideration can be treated as exogenous. Here both test statistics are highly significant, so we reject the null of exogeneity; we must continue to treat `hsngval` as endogenous.

◁

The difference between the Durbin and Wu–Hausman tests of endogeneity is that the former uses an estimate of the error term's variance based on the model assuming the variables being tested are exogenous, while the latter uses an estimate of the error variance based on the model assuming the variables being tested are endogenous. Under the null hypothesis that the variables being tested are exogenous, both estimates of the error variance are consistent. What we label the Wu–Hausman statistic is Wu's (1974) "T_2" statistic, which Hausman (1978) showed can be calculated very easily via linear regression. Baum, Schaffer, and Stillman (2003, 2007) provide a lucid discussion of these tests.

When you fit a model with multiple endogenous regressors, you can test the exogeneity of a subset of the regressors while continuing to treat the others as endogenous. For example, say you have three endogenous regressors, `y1`, `y2`, and `y3`, and you fit your model by typing

```
. ivregress depvar ... (y1 y2 y3 = ...)
```

Suppose you are confident that `y1` must be treated as endogenous, but you are undecided about `y2` and `y3`. To test whether `y2` and `y3` can be treated as exogenous, you would type

```
. estat endogenous y2 y3
```

The Durbin and Wu–Hausman tests assume that the error term is i.i.d. Therefore, if you requested a robust VCE at estimation time, `estat endogenous` will instead report Wooldridge's (1995) score test and a regression-based test of exogeneity. Both these tests can tolerate heteroskedastic and autocorrelated errors, while only the regression-based test is amenable to clustering.

▷ Example 2

We refit our housing model, requesting robust standard errors, and then test the exogeneity of `hsngval`:

```
. use http://www.stata-press.com/data/r12/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
  (output omitted)
. estat endogenous
  Tests of endogeneity
  Ho: variables are exogenous
  Robust score chi2(1)            =  2.10428  (p = 0.1469)
  Robust regression F(1,46)       =  4.31101  (p = 0.0435)
```

Wooldridge's score test does not reject the null hypothesis that `hsngval` is exogenous at conventional significance levels ($p = 0.1469$). However, the regression-based test does reject the null hypothesis at the 5% significance level ($p = 0.0435$). Typically, these two tests yield the same conclusion; the fact that our dataset has only 50 observations could be contributing to the discrepancy. Here we would be inclined to continue to treat `hsngval` as endogenous. Even if `hsngval` is exogenous, the 2SLS estimates are still consistent. On the other hand, if `hsngval` is in fact endogenous, the OLS estimates would not be consistent. Moreover, as we will see in our discussion of the `estat overid` command, our additional instruments may be invalid. To test whether an endogenous variable can be treated as exogenous, we must have a valid set of instruments to use to fit the model in the first place!

◁

Unlike the Durbin and Wu–Hausman tests, Wooldridge's score and the regression-based tests do not allow you to test a subset of the endogenous regressors in the model; you can test only whether all the endogenous regressors are in fact exogenous.

After GMM estimation, `estat endogenous` calculates what Hayashi (2000, 220) calls the C statistic, also known as the difference-in-Sargan statistic. The C statistic can be made robust to heteroskedasticity, autocorrelation, and clustering; and the version reported by `estat endogenous` is determined by the weight matrix requested via the `wmatrix()` option used when fitting the model with `ivregress`. Additionally, the test can be used to determine the exogeneity of a subset of the endogenous regressors, regardless of the type of weight matrix used.

If you fit your model using the LIML estimator, you can use the `hausman` command to carry out a traditional Hausman (1978) test between the OLS and LIML estimates.

estat firststage

For an excluded exogenous variable to be a valid instrument, it must be sufficiently correlated with the included endogenous regressors but uncorrelated with the error term. In recent decades, researchers have paid considerable attention to the issue of instruments that are only weakly correlated with the endogenous regressors. In such cases, the usual 2SLS, GMM, and LIML estimators are biased toward the OLS estimator, and inference based on the standard errors reported by, for example, `ivregress` can be severely misleading. For more information on the theory behind instrumental-variables estimation with weak instruments, see Nelson and Startz (1990); Staiger and Stock (1997); Hahn and Hausman (2003); the survey article by Stock, Wright, and Yogo (2002); and Angrist and Pischke (2009, chap. 4).

When the instruments are only weakly correlated with the endogenous regressors, some Monte Carlo evidence suggests that the LIML estimator performs better than the 2SLS and GMM estimators; see, for example, Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein). On the other hand, the LIML estimator often results in confidence intervals that are somewhat larger than those from the 2SLS estimator.

Moreover, using more instruments is not a solution, because the biases of instrumental-variables estimators increase with the number of instruments. See Hahn and Hausman (2003).

`estat firststage` produces several statistics for judging the explanatory power of the instruments and is most easily explained with examples.

▷ Example 3

Again building on the model fit in example 1 of [R] **ivregress**, we now explore the degree of correlation between the additional instruments `faminc`, `2.region`, `3.region`, and `4.region` and the endogenous regressor `hsngval`:

```
. use http://www.stata-press.com/data/r12/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
  (output omitted)
. estat firststage
  First-stage regression summary statistics
```

Variable	R-sq.	Adjusted R-sq.	Partial R-sq.	F(4,44)	Prob > F
hsngval	0.6908	0.6557	0.5473	13.2978	0.0000

```
  Minimum eigenvalue statistic = 13.2978
```

Critical Values	# of endogenous regressors:	1
Ho: Instruments are weak	# of excluded instruments:	4

	5%	10%	20%	30%
2SLS relative bias	16.85	10.27	6.71	5.34

	10%	15%	20%	25%
2SLS Size of nominal 5% Wald test	24.58	13.96	10.26	8.31
LIML Size of nominal 5% Wald test	5.44	3.87	3.30	2.98

To understand these results, recall that the first-stage regression is

$$\texttt{hsngval}_i = \pi_0 + \pi_1\texttt{pcturban}_i + \pi_2\texttt{faminc} + \pi_3\texttt{2.region} + \pi_4\texttt{3.region} + \pi_5\texttt{4.region} + v_i$$

where v_i is an error term. The column marked "R-sq." is the simple R^2 from fitting the first-stage regression by OLS, and the column marked "Adjusted R-sq." is the adjusted R^2 from that regression. Higher values purportedly indicate stronger instruments, and instrumental-variables estimators exhibit less bias when the instruments are strongly correlated with the endogenous variable.

Looking at just the R^2 and adjusted R^2 can be misleading, however. If `hsngval` were strongly correlated with the included exogenous variable `pcturban` but only weakly correlated with the additional instruments, then these statistics could be large even though a weak-instrument problem is present.

The partial R^2 statistic measures the correlation between `hsngval` and the additional instruments after *partialling out* the effect of `pcturban`. Unlike the R^2 and adjusted R^2 statistics, the partial R^2 statistic will not be inflated because of strong correlation between `hsngval` and `pcturban`. Bound, Jaeger, and Baker (1995) and others have promoted using this statistic.

The column marked "F(4, 44)" is an F statistic for the joint significance of π_2, π_3, π_4, and π_5, the coefficients on the additional instruments. Its p-value is listed in the column marked "Prob > F". If the F statistic is not significant, then the additional instruments have no significant explanatory power for `hsngval` after controlling for the effect of `pcturban`. However, Hall, Rudebusch, and Wilcox (1996) used Monte Carlo simulation to show that simply having an F statistic that is significant at the typical 5% or 10% level is not sufficient. Stock, Wright, and Yogo (2002) suggest that the F statistic should exceed 10 for inference based on the 2SLS estimator to be reliable when there is one endogenous regressor.

`estat firststage` also presents the Cragg and Donald (1993) minimum eigenvalue statistic as a further test of weak instruments. Stock and Yogo (2005) discuss two characterizations of weak instruments: first, weak instruments cause instrumental-variables estimators to be biased; second, hypothesis tests of parameters estimated by instrumental-variables estimators may suffer from severe size distortions. The test statistic in our example is 13.30, which is identical to the F statistic just discussed because our model contains one endogenous regressor.

The null hypothesis of each of Stock and Yogo's tests is that the set of instruments is weak. To perform these tests, we must first choose either the largest relative bias of the 2SLS estimator we are willing to tolerate or the largest rejection rate of a nominal 5% Wald test we are willing to tolerate. If the test statistic exceeds the critical value, we can conclude that our instruments are not weak.

The row marked "2SLS relative bias" contains critical values for the test that the instruments are weak based on the bias of the 2SLS estimator *relative to* the bias of the OLS estimator. For example, from past experience we might know that the OLS estimate of a parameter β may be 50% too high. Saying that we are willing to tolerate a 10% relative bias means that we are willing to tolerate a bias of the 2SLS estimator no greater than 5% (that is, 10% of 50%). In our rental rate model, if we are willing to tolerate a 10% relative bias, then we can conclude that our instruments are not weak because the test statistic of 13.30 exceeds the critical value of 10.22. However, if we were willing to tolerate only a relative bias of 5%, we would conclude that our instruments are weak because $13.30 < 16.85$.

The rows marked "2SLS Size of nominal 5% Wald test" and "LIML Size of nominal 5% Wald test" contain critical values pertaining to Stock and Yogo's (2005) second characterization of weak instruments. This characterization defines a set of instruments to be weak if a Wald test at the 5% level can have an actual rejection rate of no more than 10%, 15%, 20%, or 25%. Using the current example, suppose that we are willing to accept a rejection rate of at most 10%. Because $13.30 < 24.58$, we cannot reject the null hypothesis of weak instruments. On the other hand, if we use the LIML estimator instead, then we can reject the null hypothesis because $13.30 > 5.44$.

◁

❑ Technical note

Stock and Yogo (2005) tabulated critical values for 2SLS relative biases of 5%, 10%, 20%, and 30% for models with 1, 2, or 3 endogenous regressors and between 3 and 30 excluded exogenous variables (instruments). They also provide critical values for worst-case rejection rates of 5%, 10%, 20%, and 25% for nominal 5% Wald tests of the endogenous regressors with 1 or 2 endogenous regressors and between 1 and 30 instruments. If the model previously fit by `ivregress` has more instruments or endogenous regressors than these limits, the critical values are not shown. Stock and Yogo did not consider GMM estimators.

❑

When the model being fit contains more than one endogenous regressor, the R^2 and F statistics described above can overstate the relevance of the excluded instruments. Suppose that there are two endogenous regressors, Y_1 and Y_2, and that there are two additional instruments, z_1 and z_2. Say that z_1 is highly correlated with both Y_1 and Y_2 but z_2 is not correlated with either Y_1 or Y_2. Then the first-stage regression of Y_1 on z_1 and z_2 (along with the included exogenous variables) will produce large R^2 and F statistics, as will the regression of Y_2 on z_1, z_2, and the included exogenous variables. Nevertheless, the lack of correlation between z_2 and Y_1 and Y_2 is problematic. Here, although the order condition indicates that the model is just identified (the number of excluded instruments equals the number of endogenous regressors), the irrelevance of z_2 implies that the model is in fact not identified. Even if the model is overidentified, including irrelevant instruments can adversely affect the properties of instrumental-variables estimators, because their biases increase as the number of instruments increases.

▷ Example 4

`estat firststage` presents different statistics when the model contains multiple endogenous regressors. For illustration, we refit our model of rental rates, assuming that both `hsngval` and `faminc` are endogenously determined. We use `i.region` along with `popden`, a measure of population density, as additional instruments.

```
. ivregress 2sls rent pcturban (hsngval faminc = i.region popden)
(output omitted)
. estat firststage
Shea's partial R-squared
```

Variable	Shea's Partial R-sq.	Shea's Adj. Partial R-sq.
hsngval	0.3477	0.2735
faminc	0.1893	0.0972

```
Minimum eigenvalue statistic = 2.51666
```

Critical Values Ho: Instruments are weak	# of endogenous regressors: 2 # of excluded instruments: 4			
	5%	10%	20%	30%
2SLS relative bias	11.04	7.56	5.57	4.73
	10%	15%	20%	25%
2SLS Size of nominal 5% Wald test	16.87	9.93	7.54	6.28
LIML Size of nominal 5% Wald test	4.72	3.39	2.99	2.79

Consider the endogenous regressor `hsngval`. Part of its variation is attributable to its correlation with the other regressors `pcturban` and `faminc`. The other component of `hsngval`'s variation is peculiar to it and orthogonal to the variation in the other regressors. Similarly, we can think of the instruments as predicting the variation in `hsngval` in two ways, one stemming from the fact that the predicted values of `hsngval` are correlated with the predicted values of the other regressors and one from the variation in the predicted values of `hsngval` that is orthogonal to the variation in the predicted values of the other regressors.

What really matters for instrumental-variables estimation is whether the component of `hsngval` that is orthogonal to the other regressors can be explained by the component of the predicted value of `hsngval` that is orthogonal to the predicted values of the other regressors in the model. Shea's (1997) partial R^2 statistic measures this correlation. Because the bias of instrumental-variables estimators increases as more instruments are used, Shea's adjusted partial R^2 statistic is often used instead, as it makes a degrees-of-freedom adjustment for the number of instruments, analogous to the adjusted R^2 measure used in OLS regression. Although what constitutes a "low" value for Shea's partial R^2 depends on the specifics of the model being fit and the data used, these results, taken in isolation, do not strike us as being a particular cause for concern.

However, with this specification the minimum eigenvalue statistic is low. We cannot reject the null hypothesis of weak instruments for either of the characterizations we have discussed.

◁

By default, `estat firststage` determines which statistics to present based on the number of endogenous regressors in the model previously fit. However, you can specify the `all` option to obtain all the statistics.

❑ Technical note

If the previous estimation was conducted using `aweights`, `pweights`, or `iweights`, then the first-stage regression summary statistics are computed using those weights. However, in these cases the minimum eigenvalue statistic and its critical values are not available.

If the previous estimation included a robust VCE, then the first-stage F statistic is based on a robust VCE as well; for example, if you fit your model with an HAC VCE using the Bartlett kernel and four lags, then the F statistic reported is based on regression results using an HAC VCE using the Bartlett kernel and four lags. By default, the minimum eigenvalue statistic and its critical values are not displayed. You can use the `forcenonrobust` option to obtain them in these cases; the minimum eigenvalue statistic is computed using the weights, though the critical values reported may not be appropriate.

❑

estat overid

In addition to the requirement that instrumental variables be correlated with the endogenous regressors, the instruments must also be uncorrelated with the structural error term. If the model is overidentified, meaning that the number of additional instruments exceeds the number of endogenous regressors, then we can test whether the instruments are uncorrelated with the error term. If the model is just identified, then we cannot perform a test of overidentifying restrictions.

The estimator you used to fit the model determines which tests of overidentifying restrictions `estat overid` reports. If you used the 2SLS estimator without a robust VCE, `estat overid` reports Sargan's (1958) and Basmann's (1960) χ^2 tests. If you used the 2SLS estimator and requested a robust

VCE, Wooldridge's robust score test of overidentifying restrictions is performed instead; without a robust VCE, Wooldridge's test statistic is identical to Sargan's test statistic. If you used the LIML estimator, `estat overid` reports the Anderson–Rubin (1950) likelihood-ratio test and Basmann's (1960) F test. `estat overid` reports Hansen's (1982) J statistic if you used the GMM estimator. Davidson and MacKinnon (1993, 235–236) give a particularly clear explanation of the intuition behind tests of overidentifying restrictions. Also see Judge et al. (1985, 614–616) for a summary of tests of overidentifying restrictions for the 2SLS and LIML estimators.

Tests of overidentifying restrictions actually test two different things simultaneously. One, as we have discussed, is whether the instruments are uncorrelated with the error term. The other is that the equation is misspecified and that one or more of the excluded exogenous variables should in fact be included in the structural equation. Thus a significant test statistic could represent either an invalid instrument or an incorrectly specified structural equation.

▷ Example 5

Here we refit the model that treated just `hsngval` as endogenous using 2SLS, and then we perform tests of overidentifying restrictions:

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat overid
Tests of overidentifying restrictions:
Sargan (score) chi2(3) =  11.2877  (p = 0.0103)
Basmann chi2(3)        =  12.8294  (p = 0.0050)
```

Both test statistics are significant at the 5% test level, which means that either one or more of our instruments are invalid or that our structural model is specified incorrectly.

One possibility is that the error term in our structural model is heteroskedastic. Both Sargan's and Basmann's tests assume that the errors are i.i.d.; if the errors are not i.i.d., then these tests are not valid. Here we refit the model by requesting heteroskedasticity-robust standard errors, and then we use `estat overid` to obtain Wooldridge's score test of overidentifying restrictions, which is robust to heteroskedasticity.

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)
. estat overid
Test of overidentifying restrictions:
Score chi2(3)          =   6.8364  (p = 0.0773)
```

Here we no longer reject the null hypothesis that our instruments are valid at the 5% significance level, though we do reject the null at the 10% level. You can verify that the robust standard error on the coefficient for `hsngval` is more than twice as large as its nonrobust counterpart and that the robust standard error for `pcturban` is nearly 50% larger.

◁

❑ Technical note

The test statistic for the test of overidentifying restrictions performed after GMM estimation is simply the sample size times the value of the objective function $Q(\beta_1, \beta_2)$ defined in (5) of [R] **ivregress**, evaluated at the GMM parameter estimates. If the weighting matrix $\mathbf{W}$ is optimal, meaning that $\mathbf{W} = \mathrm{Var}(\mathbf{z}_i u_i)$, then $Q(\beta_1, \beta_2) \overset{A}{\sim} \chi^2(q)$, where q is the number of overidentifying restrictions. However, if the estimated $\mathbf{W}$ is not optimal, then the test statistic will not have an asymptotic χ^2 distribution.

Like the Sargan and Basmann tests of overidentifying restrictions for the 2SLS estimator, the Anderson–Rubin and Basmann tests after LIML estimation are predicated on the errors' being i.i.d. If the previous LIML results were reported with robust standard errors, then `estat overid` by default issues an error message and refuses to report the Anderson–Rubin and Basmann test statistics. You can use the `forcenonrobust` option to override this behavior. You can also use `forcenonrobust` to obtain the Sargan and Basmann test statistics after 2SLS estimation with robust standard errors. ❑

By default, `estat overid` issues an error message if the previous estimation was conducted using `aweights`, `pweights`, or `iweights`. You can use the `forceweights` option to override this behavior, though the test statistics may no longer have the expected χ^2 distributions.

Saved results

After 2SLS estimation, `estat endogenous` saves the following in `r()`:

Scalars

`r(durbin)`	Durbin χ^2 statistic
`r(p_durbin)`	p-value for Durbin χ^2 statistic
`r(wu)`	Wu–Hausman F statistic
`r(p_wu)`	p-value for Wu–Hausman F statistic
`r(df)`	degrees of freedom
`r(wudf_r)`	denominator degrees of freedom for Wu–Hausman F
`r(r_score)`	robust score statistic
`r(p_r_score)`	p-value for robust score statistic
`r(hac_score)`	HAC score statistic
`r(p_hac_score)`	p-value for HAC score statistic
`r(lags)`	lags used in prewhitening
`r(regF)`	regression-based F statistic
`r(p_regF)`	p-value for regression-based F statistic
`r(regFdf_n)`	regression-based F numerator degrees of freedom
`r(regFdf_r)`	regression-based F denominator degrees of freedom

After GMM estimation, `estat endogenous` saves the following in `r()`:

Scalars

`r(C)`	C χ^2 statistic
`r(p_C)`	p-value for C χ^2 statistic
`r(df)`	degrees of freedom

`estat firststage` saves the following in `r()`:

Scalars

`r(mineig)`	minimum eigenvalue statistic

Matrices

`r(mineigcv)`	critical values for minimum eigenvalue statistic
`r(multiresults)`	Shea's partial R^2 statistics
`r(singleresults)`	first-stage R^2 and F statistics

After 2SLS estimation, `estat overid` saves the following in `r()`:

Scalars

`r(lags)`	lags used in prewhitening
`r(df)`	χ^2 degrees of freedom
`r(score)`	score χ^2 statistic
`r(p_score)`	p-value for score χ^2 statistic
`r(basmann)`	Basmann χ^2 statistic
`r(p_basmann)`	p-value for Basmann χ^2 statistic
`r(sargan)`	Sargan χ^2 statistic
`r(p_sargan)`	p-value for Sargan χ^2 statistic

After LIML estimation, `estat overid` saves the following in `r()`:

Scalars

`r(ar)`	Anderson–Rubin χ^2 statistic
`r(p_ar)`	p-value for Anderson–Rubin χ^2 statistic
`r(ar_df)`	χ^2 degrees of freedom
`r(basmann)`	Basmann F statistic
`r(p_basmann)`	p-value for Basmann F statistic
`r(basmann_df_n)`	F numerator degrees of freedom
`r(basmann_df_d)`	F denominator degrees of freedom

After GMM estimation, `estat overid` saves the following in `r()`:

Scalars

`r(HansenJ)`	Hansen's J χ^2 statistic
`r(p_HansenJ)`	p-value for Hansen's J χ^2 statistic
`r(J_df)`	χ^2 degrees of freedom

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Methods and formulas are presented under the following headings:

Notation
estat endogenous
estat firststage
estat overid

Notation

Recall from [R] **ivregress** that the model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\Pi}_1 + \mathbf{X}_2\boldsymbol{\Pi}_2 + \mathbf{V} = \mathbf{Z}\boldsymbol{\Pi} + \mathbf{V}$$

where $\mathbf{y}$ is an $N \times 1$ vector of the left-hand-side variable, N is the sample size, $\mathbf{Y}$ is an $N \times p$ matrix of p endogenous regressors, $\mathbf{X}_1$ is an $N \times k_1$ matrix of k_1 included exogenous regressors, $\mathbf{X}_2$ is an $N \times k_2$ matrix of k_2 excluded exogenous variables, $\mathbf{X} = [\mathbf{Y}\ \mathbf{X}_1]$, $\mathbf{Z} = [\mathbf{X}_1\ \mathbf{X}_2]$, $\mathbf{u}$ is an $N \times 1$ vector of errors, $\mathbf{V}$ is an $N \times p$ matrix of errors, $\boldsymbol{\beta} = [\boldsymbol{\beta}_1\ \boldsymbol{\beta}_2]$ is a $k = (p + k_1) \times 1$ vector of parameters, and $\boldsymbol{\Pi}$ is a $(k_1 + k_2) \times p$ vector of parameters. If a constant term is included in the model, then one column of $\mathbf{X}_1$ contains all ones.

estat endogenous

Partition $\mathbf{Y}$ as $\mathbf{Y} = [\mathbf{Y}_1\ \mathbf{Y}_2]$, where $\mathbf{Y}_1$ represents the p_1 endogenous regressors whose endogeneity is being tested and $\mathbf{Y}_2$ represents the p_2 endogenous regressors whose endogeneity is not being tested. If the endogeneity of all endogenous regressors is being tested, $\mathbf{Y} = \mathbf{Y_1}$ and $p_2 = 0$. After GMM estimation, `estat endogenous` refits the model treating $\mathbf{Y}_1$ as exogenous using the same type of weight matrix as requested at estimation time with the `wmatrix()` option; denote the Sargan statistic from this model by J_e and the estimated weight matrix by $\mathbf{W}_e$. Let $\mathbf{S}_e = \mathbf{W}_e^{-1}$. `estat endogenous` removes from $\mathbf{S}_e$ the rows and columns corresponding to the variables represented by $\mathbf{Y}_1$; denote the inverse of the resulting matrix by $\mathbf{W}_e'$. Next `estat endogenous` fits the model treating both $\mathbf{Y}_1$ and $\mathbf{Y}_2$ as endogenous, using the weight matrix $\mathbf{W}_e'$; denote the Sargan statistic from this model by J_c. Then $C = (J_e - J_c) \sim \chi^2(p_1)$. If one simply used the J statistic from the original model fit by `ivregress` in place of J_c, then in finite samples $J_e - J$ might be negative. The procedure used by `estat endogenous` is guaranteed to yield $C \geq 0$; see Hayashi (2000, 220).

Let $\widehat{\mathbf{u}}_c$ denote the residuals from the model treating both $\mathbf{Y}_1$ and $\mathbf{Y}_2$ as endogenous, and let $\widehat{\mathbf{u}}_e$ denote the residuals from the model treating only $\mathbf{Y}_2$ as endogenous. Then Durbin's (1954) statistic is

$$D = \frac{\widehat{\mathbf{u}}_e'\mathbf{P}_{ZY_1}\widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}_c'\mathbf{P}_Z\widehat{\mathbf{u}}_c}{\widehat{\mathbf{u}}_e'\widehat{\mathbf{u}}_e/N}$$

where $\mathbf{P}_Z = \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$ and $\mathbf{P}_{ZY_1} = [\mathbf{Z}\ \mathbf{Y}_1]([\mathbf{Z}\ \mathbf{Y}_1]'[\mathbf{Z}\ \mathbf{Y}_1])^{-1}[\mathbf{Z}\ \mathbf{Y}_1]'$ $D \sim \chi^2(p_1)$. The Wu–Hausman (Wu 1974; Hausman 1978) statistic is

$$WH = \frac{(\widehat{\mathbf{u}}_e'\mathbf{P}_{ZY_1}\widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}_c'\mathbf{P}_Z\widehat{\mathbf{u}}_c)/p_1}{\{\widehat{\mathbf{u}}_e'\widehat{\mathbf{u}}_e - (\widehat{\mathbf{u}}_e'\mathbf{P}_{ZY_1}\widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}_c'\mathbf{P}_Z\widehat{\mathbf{u}}_c)\}/(N - k_1 - p - p_1)}$$

$WH \sim F(p_1, N - k_1 - p - p_1)$. Baum, Schaffer, and Stillman (2003, 2007) discuss these tests in more detail.

Next we describe Wooldridge's (1995) score test. The nonrobust version of Wooldridge's test is identical to Durbin's test. Suppose a robust covariance matrix was used at estimation time. Let $\widehat{\mathbf{e}}$ denote the sample residuals obtained by fitting the model via OLS, treating $\mathbf{Y}$ as exogenous. We then regress each variable represented in $\mathbf{Y}$ on $\mathbf{Z}$; call the residuals for the jth regression $\widehat{\mathbf{r}}_j$, $j = 1, \ldots, p$. Define $\widehat{k}_{ij} = \widehat{e}_i\widehat{r}_{ij}$, $i = 1, \ldots, N$. We then run the regression

$$\mathbf{1} = \theta_1\widehat{\mathbf{k}}_1 + \cdots + \theta_p\widehat{\mathbf{k}}_p + \epsilon$$

where $\mathbf{1}$ is an $N \times 1$ vector of ones and $\boldsymbol{\epsilon}$ is a regression error term. $N - \text{RSS} \sim \chi^2(p)$, where RSS is the residual sum of squares from the regression just described. If instead an HAC VCE was used at estimation time, then before running the final regression we prewhiten the $\widehat{\mathbf{k}}_j$ series by using a VAR(q) model, where q is the number of lags specified with the `lags()` option.

The regression-based test proceeds as follows. Following Hausman (1978, 1259), we regress $\mathbf{Y}$ on $\mathbf{Z}$ and obtain the residuals $\widehat{\mathbf{V}}$. Next we fit the augmented regression

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \widehat{\mathbf{V}}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

by OLS regression, where ϵ is a regression error term. A test of the exogeneity of $\mathbf{Y}$ is equivalent to a test of $\boldsymbol{\gamma} = \mathbf{0}$. As Cameron and Trivedi (2005, 276) suggest, this test can be made robust to heteroskedasticity, autocorrelation, or clustering by using the appropriate robust VCE when testing $\boldsymbol{\gamma} = \mathbf{0}$. When a nonrobust VCE is used, this test is equivalent to the Wu–Hausman test described earlier. One cannot simply fit this augmented regression via 2SLS to test the endogeneity of a subset of the endogenous regressors; Davidson and MacKinnon (1993, 229–231) discuss a test of $\boldsymbol{\gamma} = \mathbf{0}$ for the homoskedastic version of the augmented regression fit by 2SLS, but an appropriate robust test is not apparent.

estat firststage

When the structural equation includes one endogenous regressor, `estat firststage` fits the regression

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\pi}_1 + \mathbf{X}_2\boldsymbol{\pi}_2 + \mathbf{v}$$

via OLS. The R^2 and adjusted R^2 from that regression are reported in the output, as well as the F statistic from the Wald test of H_0: $\boldsymbol{\pi}_2 = \mathbf{0}$. To obtain the partial R^2 statistic, `estat firststage` fits the regression

$$\mathbf{M}_{\mathbf{X}_1}\mathbf{y} = \mathbf{M}_{\mathbf{X}_1}\mathbf{X}_2\boldsymbol{\xi} + \boldsymbol{\epsilon}$$

by OLS, where $\boldsymbol{\epsilon}$ is a regression error term, $\boldsymbol{\xi}$ is a $k_2 \times 1$ parameter vector, and $\mathbf{M}_{\mathbf{X}_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'$; that is, the partial R^2 is the R^2 between $\mathbf{y}$ and $\mathbf{X}_2$ after eliminating the effects of $\mathbf{X}_1$. If the model contains multiple endogenous regressors and the `all` option is specified, these statistics are calculated for each endogenous regressor in turn.

To calculate Shea's partial R^2, let $\mathbf{y}_1$ denote the endogenous regressor whose statistic is being calculated and $\mathbf{Y}_0$ denote the other endogenous regressors. Define $\widetilde{\mathbf{y}}_1$ as the residuals obtained from regressing $\mathbf{y}_1$ on $\mathbf{Y}_0$ and $\mathbf{X}_1$. Let $\widehat{\mathbf{y}}_1$ denote the fitted values obtained from regressing $\mathbf{y}_1$ on $\mathbf{X}_1$ and $\mathbf{X}_2$; that is, $\widehat{\mathbf{y}}_1$ are the fitted values from the first-stage regression for $\mathbf{y}_1$, and define the columns of $\widehat{\mathbf{Y}}_0$ analogously. Finally, let $\widetilde{\widehat{\mathbf{y}}}_1$ denote the residuals from regressing $\widehat{\mathbf{y}}_1$ on $\widehat{\mathbf{Y}}_0$ and $\mathbf{X}_1$. Shea's partial R^2 is the simple R^2 from the regression of $\widetilde{\mathbf{y}}_1$ on $\widetilde{\widehat{\mathbf{y}}}_1$; denote this as R^2_S. Shea's adjusted partial R^2 is equal to $1 - (1 - R^2_S)(N-1)/(N - k_Z + 1)$ if a constant term is included and $1 - (1 - R^2_S)(N-1)/(N - k_Z)$ if there is no constant term included in the model, where $k_Z = k_1 + k_2$. For one endogenous regressor, one instrument, no exogenous regressors, and a constant term, R^2_S equals the adjusted R^2_S.

The Stock and Yogo minimum eigenvalue statistic, first proposed by Cragg and Donald (1993) as a test for underidentification, is the minimum eigenvalue of the matrix

$$\mathbf{G} = \frac{1}{k_Z}\widehat{\boldsymbol{\Sigma}}_{\mathbf{VV}}^{-1/2}\mathbf{Y}'\mathbf{M}_{\mathbf{X}_1}'\mathbf{X}_2(\mathbf{X}_2'\mathbf{M}_{\mathbf{X}_1}\mathbf{X}_2)^{-1}\mathbf{X}_2'\mathbf{M}_{\mathbf{X}_1}\mathbf{Y}\widehat{\boldsymbol{\Sigma}}_{\mathbf{VV}}^{-1/2}$$

where

$$\widehat{\boldsymbol{\Sigma}}_{\mathbf{VV}} = \frac{1}{N - k_Z}\mathbf{Y}'\mathbf{M}_{\mathbf{Z}}\mathbf{Y}$$

$\mathbf{M}_{\mathbf{Z}} = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$, and $\mathbf{Z} = [\mathbf{X}_1\ \mathbf{X}_2]$. Critical values are obtained from the tables in Stock and Yogo (2005).

estat overid

The Sargan (1958) and Basmann (1960) χ^2 statistics are calculated by running the auxiliary regression

$$\widehat{\mathbf{u}} = \mathbf{Z}\boldsymbol{\delta} + \mathbf{e}$$

where $\widehat{\mathbf{u}}$ are the sample residuals from the model and $\mathbf{e}$ is an error term. Then Sargan's statistic is

$$S = N\left(1 - \frac{\widehat{\mathbf{e}}'\widehat{\mathbf{e}}}{\widehat{\mathbf{u}}'\widehat{\mathbf{u}}}\right)$$

where $\widehat{\mathbf{e}}$ are the residuals from that auxiliary regression. Basmann's statistic is calculated as

$$B = S\frac{N - k_Z}{N - S}$$

Both S and B are distributed $\chi^2(m)$, where m, the number of overidentifying restrictions, is equal to $k_Z - k$, where k is the number of endogenous regressors.

Wooldridge's (1995) score test of overidentifying restrictions is identical to Sargan's (1958) statistic under the assumption of i.i.d. and therefore is not recomputed unless a robust VCE was used at estimation time. If a heteroskedasticity-robust VCE was used, Wooldridge's test proceeds as follows. Let $\widehat{\mathbf{Y}}$ denote the $N \times k$ matrix of fitted values obtained by regressing the endogenous regressors on $\mathbf{X}_1$ and $\mathbf{X}_2$. Let $\mathbf{Q}$ denote an $N \times m$ matrix of excluded exogenous variables; the test statistic to be calculated is invariant to whichever m of the k_2 excluded exogenous variables is chosen. Define the ith element of $\widehat{\mathbf{k}}_j$, $i = 1, \ldots, N$, $j = 1, \ldots, m$, as

$$k_{ij} = \widehat{q}_{ij} u_i$$

where $\widehat{q}_{ij}$ is the ith element of $\widehat{\mathbf{q}}_j$, the fitted values from regressing the jth column of $\mathbf{Q}$ on $\widehat{\mathbf{Y}}$ and $\mathbf{X}_1$. Finally, fit the regression

$$\mathbf{1} = \theta_1 \widehat{\mathbf{k}}_1 + \cdots + \theta_m \widehat{\mathbf{k}}_m + \boldsymbol{\epsilon}$$

where $\mathbf{1}$ is an $N \times 1$ vector of ones and $\boldsymbol{\epsilon}$ is a regression error term, and calculate the residual sum of squares, RSS. Then the test statistic is $W = N - \text{RSS}$. $W \sim \chi^2(m)$. If an HAC VCE was used at estimation, then the $\widehat{\mathbf{k}}_j$ are prewhitened using a VAR(p) model, where p is specified using the `lags()` option.

The Anderson–Rubin (1950), AR, test of overidentifying restrictions for use after the LIML estimator is calculated as $\text{AR} = N(\kappa - 1)$, where κ is the minimal eigenvalue of a certain matrix defined in *Methods and formulas* of [R] **ivregress**. $\text{AR} \sim \chi^2(m)$. (Some texts define this statistic as $N \ln(\kappa)$ because $\ln(x) \approx (x - 1)$ for x near one.) Basmann's F statistic for use after the LIML estimator is calculated as $B_F = (\kappa - 1)(N - k_Z)/m$. $B_F \sim F(m, N - k_Z)$.

Hansen's J statistic is simply the sample size times the value of the GMM objective function defined in (5) of [R] **ivregress**, evaluated at the estimated parameter values. Under the null hypothesis that the overidentifying restrictions are valid, $J \sim \chi^2(m)$.

Title

ivtobit — Tobit model with continuous endogenous regressors

Syntax

Maximum likelihood estimator

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight],
    ll[(#)] ul[(#)] [mle_options]
```

Two-step estimator

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep
    ll[(#)] ul[(#)] [tse_options]
```

mle_options	Description
Model	
*`ll[(#)]`	lower limit for left censoring
*`ul[(#)]`	upper limit for right censoring
`mle`	use conditional maximum-likelihood estimator; the default
`constraints(`*constraints*`)`	apply specified linear constraints
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`first`	report first-stage regression
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process
`coeflegend`	display legend instead of statistics

*You must specify at least one of `ll[(#)]` and `ul[(#)]`.

tse_options	Description
Model	
*twostep	use Newey's two-step estimator; the default is mle
*ll[(#)]	lower limit for left censoring
*ul[(#)]	upper limit for right censoring
SE	
vce(*vcetype*)	*vcetype* may be twostep, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
first	report first-stage regression
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
coeflegend	display legend instead of statistics

*twostep is required. You must specify at least one of ll[(#)] and ul[(#)].

varlist$_1$ and *varlist*$_{\text{iv}}$ may contain factor variables; see [U] **11.4.3 Factor variables**.
depvar, *varlist*$_1$, *varlist*$_2$, and *varlist*$_{\text{iv}}$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.
vce(), first, twostep, and weights are not allowed with the svy prefix; see [SVY] **svy**.
fweights, iweights, and pweights are allowed with the maximum likelihood estimator. fweights are allowed with Newey's two-step estimator. See [U] **11.1.6 weight**.
coeflegend does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Endogenous covariates > Tobit model with endogenous covariates

Description

ivtobit fits tobit models where one or more of the regressors is endogenously determined. By default, ivtobit uses maximum likelihood estimation. Alternatively, Newey's (1987) minimum chi-squared estimator can be invoked with the twostep option. Both estimators assume that the endogenous regressors are continuous and so are not appropriate for use with discrete endogenous regressors. See [R] **ivprobit** for probit estimation with endogenous regressors and [R] **tobit** for tobit estimation when the model contains no endogenous regressors.

Options for ML estimator

Model

ll(#) and ul(#) indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with *depvar* $\leq$ ll() are left-censored; observations with *depvar* $\geq$ ul() are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type ll, ul, or both. When you do not specify a censoring value, ivtobit assumes that the lower limit is the minimum observed in the data (if ll is specified) and that the upper limit is the maximum (if ul is specified).

`mle` requests that the conditional maximum-likelihood estimator be used. This is the default.

`constraints(`*constraints*`)`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. This model's likelihood function can be difficult to maximize, especially with multiple endogenous variables. The `difficult` and `technique(bfgs)` options may be helpful in achieving convergence.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `ivtobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Options for two-step estimator

Model

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`ll(#)` and `ul(#)` indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with *depvar* $\leq$ `ll()` are left-censored; observations with *depvar* $\geq$ `ul()` are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type `ll`, `ul`, or both. When you do not specify a censoring value, `ivtobit` assumes that the lower limit is the minimum observed in the data (if `ll` is specified) and that the upper limit is the maximum (if `ul` is specified).

SE

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `ivtobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

`ivtobit` fits models with censored dependent variables and endogenous regressors. You can use it to fit a tobit model when you suspect that one or more of the regressors is correlated with the error term. `ivtobit` is to tobit what `ivregress` is to linear regression analysis; see [R] **ivregress** for more information.

Formally, the model is

$$y_{1i}^* = \boldsymbol{y}_{2i}\boldsymbol{\beta} + \boldsymbol{x}_{1i}\boldsymbol{\gamma} + u_i$$
$$\boldsymbol{y}_{2i} = \boldsymbol{x}_{1i}\boldsymbol{\Pi}_1 + \boldsymbol{x}_{2i}\boldsymbol{\Pi}_2 + \boldsymbol{v}_i$$

where $i = 1, \ldots, N$; $\boldsymbol{y}_{2i}$ is a $1 \times p$ vector of endogenous variables; $\boldsymbol{x}_{1i}$ is a $1 \times k_1$ vector of exogenous variables; $\boldsymbol{x}_{2i}$ is a $1 \times k_2$ vector of additional instruments; and the equation for $\boldsymbol{y}_{2i}$ is written in reduced form. By assumption $(u_i, \boldsymbol{v}_i) \sim \mathrm{N}(\boldsymbol{0})$. $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ are vectors of structural parameters, and $\boldsymbol{\Pi}_1$ and $\boldsymbol{\Pi}_2$ are matrices of reduced-form parameters. We do not observe y_{1i}^*; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \le y_{1i}^* \le b \\ b & y_{1i}^* > b \end{cases}$$

The order condition for identification of the structural parameters is that $k_2 \ge p$. Presumably, $\boldsymbol{\Sigma}$ is not block diagonal between u_i and $\boldsymbol{v}_i$; otherwise, $\boldsymbol{y}_{2i}$ would not be endogenous.

❑ Technical note

This model is derived under the assumption that $(u_i, \boldsymbol{v}_i)$ is independent and identically distributed multivariate normal for all i. The `vce(cluster` *clustvar*`)` option can be used to control for a lack of independence. As with the standard tobit model without endogeneity, if u_i is heteroskedastic, point estimates will be inconsistent.

❑

Example 1

Using the same dataset as in [R] **ivprobit**, we now want to estimate women's incomes. In our hypothetical world, all women who choose not to work receive $10,000 in welfare and child-support payments. Therefore, we never observe incomes under $10,000: a woman offered a job with an annual wage less than that would not accept and instead would collect the welfare payment. We model income as a function of the number of years of schooling completed, the number of children at home, and other household income. We again believe that `other_inc` is endogenous, so we use `male_educ` as an instrument.

  Obs. summary:        272  left-censored observations at fem_inc<=10
                       228     uncensored observations
                         0 right-censored observations
```

Because we did not specify `mle` or `twostep`, `ivtobit` used the maximum likelihood estimator by default. `ivtobit` fits a tobit model, ignoring endogeneity, to get starting values for the full model. The header of the output contains the maximized log likelihood, the number of observations, and a Wald statistic and p-value for the test of the hypothesis that all the slope coefficients are jointly zero. At the end of the output, we see a count of the censored and uncensored observations.

Near the bottom of the output is a Wald test of the exogeneity of the instrumented variables. If the test statistic is not significant, there is not sufficient information in the sample to reject the null hypothesis of no endogeneity. Then the point estimates from `ivtobit` are consistent, although those from `tobit` are likely to have smaller standard errors.

◁

Various two-step estimators have also been proposed for the endogenous tobit model, and Newey's (1987) minimum chi-squared estimator is available with the `twostep` option.

▷ Example 2

Refitting our labor-supply model with the two-step estimator yields

```
. ivtobit fem_inc fem_educ kids (other_inc = male_educ), ll twostep
Two-step tobit with endogenous regressors         Number of obs   =       500
                                                  Wald chi2(3)    =    117.38
                                                  Prob > chi2     =    0.0000
------------------------------------------------------------------------------
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
   other_inc |  -.9045397   .1330015    -6.80   0.000    -1.165218   -.6438616
    fem_educ |    3.27239   .3969399     8.24   0.000     2.494402    4.050378
        kids |  -3.312356   .7220066    -4.59   0.000    -4.727463   -1.897249
       _cons |   19.24735    7.37392     2.61   0.009     4.794728    33.69997
------------------------------------------------------------------------------
Instrumented:  other_inc
Instruments:   fem_educ kids male_educ
------------------------------------------------------------------------------
Wald test of exogeneity:     chi2(1) =     4.64           Prob > chi2 = 0.0312
  Obs. summary:        272  left-censored observations at fem_inc<=10
                       228     uncensored observations
                         0 right-censored observations
```

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity.

◁

❑ Technical note

In the tobit model with endogenous regressors, we assume that $(u_i, \boldsymbol{v}_i)$ is multivariate normal with covariance matrix

$$\mathrm{Var}(u_i, \boldsymbol{v}_i) = \boldsymbol{\Sigma} = \begin{bmatrix} \sigma_u^2 & \boldsymbol{\Sigma}_{21}' \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution, $\mathrm{Var}(u_i|\boldsymbol{v}_i) \equiv \sigma^2_{u|v} = \sigma_u^2 - \boldsymbol{\Sigma}_{21}'\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$. Calculating the marginal effects on the conditional expected values of the observed and latent dependent variables and on the probability of censoring requires an estimate of σ_u^2. The two-step estimator identifies only $\sigma^2_{u|v}$, not σ_u^2, so only the linear prediction and its standard error are available after you have used the `twostep` option. However, unlike the two-step probit estimator described in [R] **ivprobit**, the two-step tobit estimator does identify $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$. See Wooldridge (2010, 683–684) for more information.

Methods and formulas

ivtobit is implemented as an ado-file.

The estimation procedure used by ivtobit is similar to that used by ivprobit. For compactness, we write the model as

$$y_{1i}^* = \boldsymbol{z}_i\boldsymbol{\delta} + u_i \tag{1a}$$
$$\boldsymbol{y}_{2i} = \boldsymbol{x}_i\boldsymbol{\Pi} + \boldsymbol{v}_i \tag{1b}$$

where $\boldsymbol{z}_i = (\boldsymbol{y}_{2i}, \boldsymbol{x}_{1i})$, $\boldsymbol{x}_i = (\boldsymbol{x}_{1i}, \boldsymbol{x}_{2i})$, $\boldsymbol{\delta} = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$, and $\boldsymbol{\Pi} = (\boldsymbol{\Pi}_1', \boldsymbol{\Pi}_2')'$. We do not observe y_{1i}^*; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \le y_{1i}^* \le b \\ b & y_{1i}^* > b \end{cases}$$

$(u_i, \boldsymbol{v}_i)$ is distributed multivariate normal with mean zero and covariance matrix

$$\boldsymbol{\Sigma} = \begin{bmatrix} \sigma_u^2 & \boldsymbol{\Sigma}_{21}' \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution, we can write $u_i = \boldsymbol{v}_i'\boldsymbol{\alpha} + \epsilon_i$, where $\boldsymbol{\alpha} = \boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$; $\epsilon_i \sim \mathrm{N}(0; \sigma_{u|v}^2)$, where $\sigma_{u|v}^2 = \sigma_u^2 - \boldsymbol{\Sigma}_{21}'\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$; and ϵ_i is independent of $\boldsymbol{v}_i$, $\boldsymbol{z}_i$, and $\boldsymbol{x}_i$.

The likelihood function is straightforward to derive because we can write the joint density $f(y_{1i}, \boldsymbol{y}_{2i}|\boldsymbol{x}_i)$ as $f(y_{1i}|\boldsymbol{y}_{2i}, \boldsymbol{x}_i)\, f(\boldsymbol{y}_{2i}|\boldsymbol{x}_i)$. With one endogenous regressor,

$$\ln f(y_{2i}|\boldsymbol{x}_i) = -\frac{1}{2}\left\{ \ln 2\pi + \ln\sigma_v^2 + \frac{(y_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi})^2}{\sigma_v^2} \right\}$$

and

$$\ln f(y_{1i}|y_{2i}, \boldsymbol{x}_i) = \begin{cases} \ln\left\{1 - \Phi\left(\frac{m_i - a}{\sigma_{u|v}}\right)\right\} & y_{1i} = a \\ -\frac{1}{2}\left\{ \ln 2\pi + \ln\sigma_{u|v}^2 + \frac{(y_{1i} - m_i)^2}{\sigma_{u|v}^2} \right\} & a < y_{1i} < b \\ \ln\Phi\left(\frac{m_i - b}{\sigma_{u|v}}\right) & y_{1i} = b \end{cases}$$

where

$$m_i = \boldsymbol{z}_i\boldsymbol{\delta} + \alpha\,(y_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi})$$

and $\Phi(\cdot)$ is the normal distribution function so that the log likelihood for observation i is

$$\ln L_i = w_i\left\{ \ln f(y_{1i}|y_{2i}, \boldsymbol{x}_i) + \ln f(y_{2i}|\boldsymbol{x}_i) \right\}$$

where w_i is the weight for observation i or one if no weights were specified. Instead of estimating $\sigma_{u|v}$ and σ_v directly, we estimate $\ln\sigma_{u|v}$ and $\ln\sigma_v$.

For multiple endogenous regressors, we have

$$\ln f(\boldsymbol{y}_{2i}|\boldsymbol{x}_i) = -\frac{1}{2}\left(\ln 2\pi + \ln|\boldsymbol{\Sigma}_{22}| + \boldsymbol{v}_i'\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{v}_i \right)$$

and $\ln f(y_{1i}|\boldsymbol{y}_{2i}, \boldsymbol{x}_i)$ is the same as before, except that now

$$m_i = \boldsymbol{z}_i\boldsymbol{\delta} + (\boldsymbol{y}_{2i} - \boldsymbol{x}_i\boldsymbol{\Pi})\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$$

Instead of maximizing the log-likelihood function with respect to $\boldsymbol{\Sigma}$, we maximize with respect to the Cholesky decomposition $\boldsymbol{S}$ of $\boldsymbol{\Sigma}$; that is, there exists a lower triangular matrix $\boldsymbol{S}$ such that $\boldsymbol{S}\boldsymbol{S}' = \boldsymbol{\Sigma}$. This maximization ensures that $\boldsymbol{\Sigma}$ is positive definite, as a covariance matrix must be. Let

$$\boldsymbol{S} = \begin{bmatrix} s_{11} & 0 & 0 & \dots & 0 \\ s_{21} & s_{22} & 0 & \dots & 0 \\ s_{31} & s_{32} & s_{33} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ s_{p+1,1} & s_{p+1,2} & s_{p+1,3} & \dots & s_{p+1,p+1} \end{bmatrix}$$

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of `ivtobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

The two-step estimates are obtained using Newey's (1987) minimum chi-squared estimator. The procedure is identical to the one described in [R] **ivprobit**, except that `tobit` is used instead of `probit`.

Acknowledgments

The two-step estimator is based on the `tobitiv` command written by Jonah Gelbach, Department of Economics, Yale University, and the `ivtobit` command written by Joe Harkness, Institute of Policy Studies, Johns Hopkins University.

Title

ivtobit postestimation — Postestimation tools for ivtobit

Description

The following postestimation commands are available after `ivtobit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`[1]	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[2]	likelihood-ratio test; not available with two-step estimator
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`[1]	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `estat ic` and `suest` are not appropriate after `ivtobit, twostep`.

[2] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat (svy)`.

Syntax for predict

After ML or twostep

```
predict [type] newvar [if] [in] [, statistic]
```

After ML

```
predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the linear prediction
`stdf`	standard error of the forecast; not available with two-step estimator
`pr(`*a*`,`*b*`)`	$\Pr(a < y_j < b)$; not available with two-step estimator
`e(`*a*`,`*b*`)`	$E(y_j \mid a < y_j < b)$; not available with two-step estimator
`ystar(`*a*`,`*b*`)`	$E(y_j^*)$, $y_j = \max\{a, \min(y_j, b)\}$; not available with two-step estimator

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing ($a \geq .$) means $-\infty$, and *b* missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**. `stdf` is not available with the two-step estimator.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$; `pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which *lb* $\geq .$ and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$; `pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which *ub* $\geq .$ and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`pr(`*a*`,`*b*`)` is not available with the two-step estimator.

`e(`*a*`,`*b*`)` calculates $E(\boldsymbol{x}_j\boldsymbol{b} + u_j \mid a < \boldsymbol{x}_j\boldsymbol{b} + u_j < b)$, the expected value of $y_j|\boldsymbol{x}_j$ conditional on $y_j|\boldsymbol{x}_j$ being in the interval (a, b), meaning that $y_j|\boldsymbol{x}_j$ is truncated. a and b are specified as they are for `pr()`. `e(`*a*`,`*b*`)` is not available with the two-step estimator.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\boldsymbol{x}_j\boldsymbol{b} + u_j \leq a$, $y_j^* = b$ if $\boldsymbol{x}_j\boldsymbol{b} + u_j \geq b$, and $y_j^* = \boldsymbol{x}_j\boldsymbol{b} + u_j$ otherwise, meaning that y_j^* is censored. a and b are specified as they are for `pr()`. `ystar(`*a*`,`*b*`)` is not available with the two-step estimator.

`scores`, not available with `twostep`, calculates equation-level score variables.

For models with one endogenous regressor, five new variables are created.

The first new variable will contain $\partial \ln L/\partial(\boldsymbol{z}_i\boldsymbol{\delta})$.

The second new variable will contain $\partial \ln L/\partial(\boldsymbol{x}_i\boldsymbol{\Pi})$.

The third new variable will contain $\partial \ln L/\partial\alpha$.

The fourth new variable will contain $\partial \ln L/\partial \ln\sigma_{u|v}$.

The fifth new variable will contain $\partial \ln L/\partial \ln\sigma_v$.

For models with p endogenous regressors, $p + \{(p+1)(p+2)\}/2 + 1$ new variables are created.

The first new variable will contain $\partial \ln L/\partial(\boldsymbol{z}_i\boldsymbol{\delta})$.

The second through $(p+1)$th new score variables will contain $\partial \ln L/\partial(\boldsymbol{x}_i\boldsymbol{\Pi}_k)$, $k = 1, \ldots, p$, where $\boldsymbol{\Pi}_k$ is the kth column of $\boldsymbol{\Pi}$.

The remaining score variables will contain the partial derivatives of $\ln L$ with respect to s_{11}, s_{21}, …, $s_{p+1,1}$, s_{22}, …, $s_{p+1,2}$, …, $s_{p+1,p+1}$, where $s_{m,n}$ denotes the (m, n) element of the Cholesky decomposition of the error covariance matrix.

Remarks

Remarks are presented under the following headings:

Marginal effects
Obtaining predicted values

Marginal effects

▷ Example 1

We can obtain average marginal effects by using the `margins` command after `ivtobit`. For the labor-supply model of example 1 in [R] **ivtobit**, suppose that we wanted to know the average marginal effects on the woman's expected income, conditional on her income being greater than $10,000.

```
. use http://www.stata-press.com/data/r12/laborsup
. ivtobit fem_inc fem_educ kids (other_inc = male_educ), ll
  (output omitted)
. margins, dydx(*) predict(e(10, .))
Average marginal effects                        Number of obs   =        500
Model VCE    : OIM
Expression   : E(fem_inc|fem_inc>10), predict(e(10, .))
dy/dx w.r.t. : other_inc fem_educ kids male_educ
```

	Delta-method dy/dx	Std. Err.	z	P>|z|	[95% Conf.	Interval]
other_inc	-.3420189	.0553591	-6.18	0.000	-.4505208	-.233517
fem_educ	1.237336	.1534025	8.07	0.000	.9366723	1.537999
kids	-1.252447	.2725166	-4.60	0.000	-1.78657	-.7183246
male_educ	0	(omitted)				

In our sample, increasing the number of children in the family by one decreases the expected wage by \$1,252 on average (wages in our dataset are measured in thousands of dollars). `male_edu` has no effect because it appears only as an instrument.

◁

Obtaining predicted values

After fitting your model using `ivtobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples using the `predict` command. If you used the maximum likelihood estimator, you can also obtain conditional expected values of the observed and latent dependent variables, the standard error of the forecast, and the probability of observing the dependent variable in a specified interval. See [U] **20 Estimation and postestimation commands** and [R] **predict**.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

The linear prediction is calculated as $\boldsymbol{z}_i\widehat{\boldsymbol{\delta}}$, where $\widehat{\boldsymbol{\delta}}$ is the estimated value of $\boldsymbol{\delta}$, and $\boldsymbol{z}_i$ and $\boldsymbol{\delta}$ are defined in (1a) of [R] **ivtobit**. Expected values and probabilities are calculated using the same formulas as those used by the standard exogenous tobit model.

Title

jackknife — Jackknife estimation

Syntax

`jackknife` *exp_list* [`,` *options eform_option*] `:` *command*

options	Description
Main	
`eclass`	number of observations used is stored in `e(N)`
`rclass`	number of observations used is stored in `r(N)`
`n(`*exp*`)`	specify *exp* that evaluates to the number of observations used
Options	
`cluster(`*varlist*`)`	variables identifying sample clusters
`idcluster(`*newvar*`)`	create new cluster ID variable
`saving(`*filename*`, ...)`	save results to *filename*; save statistics in double precision; save results to *filename* every # replications
`keep`	keep pseudovalues
`mse`	use MSE formula for variance estimation
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`notable`	suppress table of results
`noheader`	suppress table header
`nolegend`	suppress table legend
`verbose`	display the full table legend
`nodots`	suppress replication dots
`noisily`	display any output from *command*
`trace`	trace *command*
`title(`*text*`)`	use *text* as title for jackknife results
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Advanced	
`nodrop`	do not drop observations
`reject(`*exp*`)`	identify invalid results
eform_option	display coefficient table in exponentiated form
`coeflegend`	display legend instead of statistics

`svy` is allowed; see [SVY] **svy jackknife**.

All weight types supported by *command* are allowed except `aweights`; see [U] **11.1.6 weight**.

eform_option and `coeflegend` do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

exp_list contains	(*name*: *elist*)
	elist
	eexp
elist contains	*newvar* = (*exp*)
	(*exp*)
eexp is	*specname*
	[*eqno*]*specname*
specname is	_b
	_b[]
	_se
	_se[]
eqno is	##
	name

exp is a standard Stata expression; see [U] **13 Functions and expressions**.

Distinguish between `[]`, which are to be typed, and [ ], which indicate optional arguments.

Menu

Statistics > Resampling > Jackknife estimation

Description

`jackknife` performs jackknife estimation. Typing

```
. jackknife exp_list: command
```

executes *command* once for each observation in the dataset, leaving the associated observation out of the calculations that make up *exp_list*.

command defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `jackknife`, as long as they follow standard Stata syntax and allow the `if` qualifier; see [U] **11 Language syntax**. The `by` prefix may not be part of *command*.

exp_list specifies the statistics to be collected from the execution of *command*. If *command* changes the contents in `e(b)`, *exp_list* is optional and defaults to `_b`.

Many estimation commands allow the `vce(jackknife)` option. For those commands, we recommend using `vce(jackknife)` over `jackknife` because the estimation command already handles clustering and other model-specific details for you. The `jackknife` prefix command is intended for use with nonestimation commands, such as `summarize`, user-written commands, or functions of coefficients.

`jknife` is a synonym for `jackknife`.

Options

Main

`eclass`, `rclass`, and `n(`*exp*`)` specify where *command* saves the number of observations on which it based the calculated results. We strongly advise you to specify one of these options.

`eclass` specifies that *command* save the number of observations in `e(N)`.

`rclass` specifies that *command* save the number of observations in `r(N)`.

`n(`*exp*`)` specifies an expression that evaluates to the number of observations used. Specifying `n(r(N))` is equivalent to specifying the `rclass` option. Specifying `n(e(N))` is equivalent to specifying the `eclass` option. If *command* saves the number of observations in `r(N1)`, specify `n(r(N1))`.

If you specify no options, `jackknife` will assume `eclass` or `rclass`, depending on which of `e(N)` and `r(N)` is not missing (in that order). If both `e(N)` and `r(N)` are missing, `jackknife` assumes that all observations in the dataset contribute to the calculated result. If that assumption is incorrect, the reported standard errors will be incorrect. For instance, say that you specify

```
. jackknife coef=_b[x2]: myreg y x1 x2 x3
```

where `myreg` uses `e(n)` instead of `e(N)` to identify the number of observations used in calculations. Further assume that observation 42 in the dataset has `x3` equal to missing. The 42nd observation plays no role in obtaining the estimates, but `jackknife` has no way of knowing that and will use the wrong N. If, on the other hand, you specify

```
. jackknife coef=_b[x2], n(e(n)): myreg y x1 x2 x3
```

`jackknife` will notice that observation 42 plays no role. The `n(e(n))` option is specified because `myreg` is an estimation command but it saves the number of observations used in `e(n)` (instead of the standard `e(N)`). When `jackknife` runs the regression omitting the 42nd observation, `jackknife` will observe that `e(n)` has the same value as when `jackknife` previously ran the regression using all the observations. Thus `jackknife` will know that `myreg` did not use the observation.

Options

`cluster(`*varlist*`)` specifies the variables identifying sample clusters. If `cluster()` is specified, one cluster is left out of each call to *command*, instead of 1 observation.

`idcluster(`*newvar*`)` creates a new variable containing a unique integer identifier for each resampled cluster, starting at `1` and leading up to the number of clusters. This option may be specified only when the `cluster()` option is specified. `idcluster()` helps identify the cluster to which a pseudovalue belongs.

`saving(`*filename*`[ , `*suboptions*`])` creates a Stata data file (`.dta` file) consisting of (for each statistic in *exp_list*) a variable containing the replicates.

`double` specifies that the results for each replication be stored as `double`s, meaning 8-byte reals. By default, they are stored as `float`s, meaning 4-byte reals. This option may be used without the `saving()` option to compute the variance estimates by using double precision.

`every(#)` specifies that results be written to disk every #th replication. `every()` should be specified only in conjunction with `saving()` when *command* takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer. See [P] **postfile**.

`replace` specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

`keep` specifies that new variables be added to the dataset containing the pseudovalues of the requested statistics. For instance, if you typed

```
. jackknife coef=_b[x2], eclass keep: regress y x1 x2 x3
```

new variable `coef` would be added to the dataset containing the pseudovalues for `_b[x2]`. Let b be the value of `_b[x2]` when all observations are used to fit the model, and let $b(j)$ be the value when the jth observation is omitted. The pseudovalues are defined as

$$\text{pseudovalue}_j = N\{b - b(j)\} + b(j)$$

where N is the number of observations used to produce b.

When the `cluster()` option is specified, each cluster is given at most one nonmissing pseudovalue. The `keep` option implies the `nodrop` option.

`mse` specifies that `jackknife` compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, `jackknife` computes the variance by using deviations of the pseudovalues from their mean.

Reporting

`level(#)`; see [R] **estimation options**.

`notable` suppresses the display of the table of results.

`noheader` suppresses the display of the table header. This option implies `nolegend`.

`nolegend` suppresses the display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

`verbose` specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`nodots` suppresses display of the replication dots. By default, one dot character is displayed for each successful replication. A red 'x' is displayed if *command* returns an error or if one of the values in *exp_list* is missing.

`noisily` specifies that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(`*text*`)` specifies a title to be displayed above the table of jackknife results; the default title is `Jackknife results` or what is produced in `e(title)` by an estimation command.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Advanced

`nodrop` prevents observations outside `e(sample)` and the `if` and `in` qualifiers from being dropped before the data are resampled.

`reject(`*exp*`)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

The following options are available with `jackknife` but are not shown in the dialog box:

eform_option causes the coefficient table to be displayed in exponentiated form; see [R] ***eform_option***. *command* determines which *eform_option* is allowed (`eform(`*string*`)` and `eform` are always allowed).

command determines which of the following are allowed (`eform(`*string*`)` and `eform` are always allowed):

eform_option	Description
`eform(`*string*`)`	use *string* for the column title
`eform`	exponentiated coefficient, *string* is `exp(b)`
`hr`	hazard ratio, *string* is `Haz. Ratio`
`shr`	subhazard ratio, *string* is `SHR`
`irr`	incidence-rate ratio, *string* is `IRR`
`or`	odds ratio, *string* is `Odds Ratio`
`rrr`	relative-risk ratio, *string* is `RRR`

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Jackknifed standard deviation
Collecting multiple statistics
Collecting coefficients

Introduction

Although the jackknife—developed in the late 1940s and early 1950s—is of largely historical interest today, it is still useful in searching for overly influential observations. This feature is often forgotten. In any case, the jackknife is

- an alternative, first-order unbiased estimator for a statistic;
- a data-dependent way to calculate the standard error of the statistic and to obtain significance levels and confidence intervals; and
- a way of producing measures called pseudovalues for each observation, reflecting the observation's influence on the overall statistic.

The idea behind the simplest form of the jackknife—the one implemented here—is to repeatedly calculate the statistic in question, each time omitting just one of the dataset's observations. Assume that our statistic of interest is the sample mean. Let y_j be the jth observation of our data on some measurement y, where $j = 1, \ldots, N$ and N is the sample size. If $\overline{y}$ is the sample mean of y using the entire dataset and $\overline{y}_{(j)}$ is the mean when the jth observation is omitted, then

$$\overline{y} = \frac{(N-1)\,\overline{y}_{(j)} + y_j}{N}$$

Solving for y_j, we obtain

$$y_j = N\,\overline{y} - (N-1)\,\overline{y}_{(j)}$$

These are the pseudovalues that `jackknife` calculates. To move this discussion beyond the sample mean, let $\widehat{\theta}$ be the value of our statistic (not necessarily the sample mean) using the entire dataset, and let $\widehat{\theta}_{(j)}$ be the computed value of our statistic with the jth observation omitted. The pseudovalue for the jth observation is

$$\widehat{\theta}^{*}_{j} = N\,\widehat{\theta} - (N-1)\,\widehat{\theta}_{(j)}$$

The mean of the pseudovalues is the alternative, first-order unbiased estimator mentioned above, and the standard error of the mean of the pseudovalues is an estimator for the standard error of $\widehat{\theta}$ (Tukey 1958).

When the `cluster()` option is given, clusters are omitted instead of observations, and N is the number of clusters instead of the sample size.

The jackknife estimate of variance has been largely replaced by the bootstrap estimate (see [R] **bootstrap**), which is widely viewed as more efficient and robust. The use of jackknife pseudovalues to detect outliers is too often forgotten and is something the bootstrap does not provide. See Mosteller and Tukey (1977, 133–163) and Mooney and Duval (1993, 22–27) for more information.

▷ Example 1

As our first example, we will show that the jackknife standard error of the sample mean is equivalent to the standard error of the sample mean computed using the classical formula in the `ci` command. We use the `double` option to compute the standard errors with the same precision as the `ci` command.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. jackknife r(mean), double: summarize mpg
Jackknife replications (74)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
........................
Jackknife results                               Number of obs      =        74
                                                Replications       =        74

      command:  summarize mpg, mean
        _jk_1:  r(mean)
          n():  r(N)

------------------------------------------------------------------------------
             |              Jackknife
             |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       _jk_1 |     21.2973   .6725511    31.67   0.000      19.9569     22.63769
------------------------------------------------------------------------------

. ci mpg
    Variable |        Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+---------------------------------------------------------------
         mpg |         74     21.2973    .6725511        19.9569     22.63769
```

◁

Jackknifed standard deviation

▷ Example 2

Mosteller and Tukey (1977, 139–140) request a 95% confidence interval for the standard deviation of the 11 values:

0.1, 0.1, 0.1, 0.4, 0.5, 1.0, 1.1, 1.3, 1.9, 1.9, 4.7

Stata's `summarize` command calculates the mean and standard deviation and saves them as `r(mean)` and `r(sd)`. To obtain the jackknifed standard deviation of the 11 values and save the pseudovalues as a new variable, `sd`, we would type

```
. clear
. input x
            x
  1. 0.1
  2. 0.1
  3. 0.1
  4. 0.4
  5. 0.5
  6. 1.0
  7. 1.1
  8. 1.3
  9. 1.9
 10. 1.9
 11. 4.7
 12. end
. jackknife sd=r(sd), rclass keep: summarize x
(running summarize on estimation sample)
Jackknife replications (11)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
...........
Jackknife results                               Number of obs      =        11
                                                Replications       =        11

      command:  summarize x
           sd:  r(sd)
         n():  r(N)

------------------------------------------------------------------------------
             |             Jackknife
             |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
          sd |    1.343469    .624405     2.15   0.057    -.047792     2.73473
------------------------------------------------------------------------------
```

Interpreting the output, the standard deviation reported by `summarize mpg` is 1.34. The jackknife standard error is 0.62. The 95% confidence interval for the standard deviation is -0.048 to 2.73.

By specifying `keep`, `jackknife` creates in our dataset a new variable, `sd`, for the pseudovalues.

```
. list, sep(4)
```

	x	sd
1.	.1	1.139977
2.	.1	1.139977
3.	.1	1.139977
4.	.4	.8893147
5.	.5	.824267
6.	1	.632489
7.	1.1	.6203189
8.	1.3	.6218889
9.	1.9	.835419
10.	1.9	.835419
11.	4.7	7.703949

The jackknife estimate is the average of the `sd` variable, so `sd` contains the individual values of our statistic. We can see that the last observation is substantially larger than the others. The last observation is certainly an outlier, but whether that reflects the considerable information it contains or indicates that it should be excluded from analysis depends on the context of the problem. Here Mosteller

and Tukey created the dataset by sampling from an exponential distribution, so the observation is informative.

◁

▷ Example 3

Let's repeat the example above using the automobile dataset, obtaining the standard error of the standard deviation of mpg.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. jackknife sd=r(sd), rclass keep: summarize mpg
(running summarize on estimation sample)
Jackknife replications (74)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
........................
Jackknife results                                 Number of obs      =        74
                                                  Replications       =        74

      command:  summarize mpg
           sd:  r(sd)
         n():  r(N)
```

	Coef.	Jackknife Std. Err.	t	P>|t|	[95% Conf.	Interval]
sd	5.785503	.6072509	9.53	0.000	4.575254	6.995753

Let's look at sd more carefully:

```
. summarize sd, detail
                    pseudovalues: r(sd)
-------------------------------------------------------------
      Percentiles      Smallest
 1%     2.870471       2.870471
 5%     2.870471       2.870471
10%     2.906255       2.870471       Obs                  74
25%     3.328489       2.870471       Sum of Wgt.          74

50%     3.948335                      Mean           5.817374
                       Largest        Std. Dev.       5.22377
75%     6.844418       17.34316
90%     9.597018        19.7617       Variance       27.28777
95%     17.34316        19.7617       Skewness        4.07202
99%     38.60905       38.60905       Kurtosis       23.37823
. list make mpg sd if sd > 30
```

	make	mpg	sd
71.	VW Diesel	41	38.60905

Here the VW Diesel is the only diesel car in our dataset.

◁

Collecting multiple statistics

▷ Example 4

`jackknife` is not limited to collecting just one statistic. For instance, we can use `summarize, detail` and then obtain the jackknife estimate of the standard deviation and skewness. `summarize, detail` saves the standard deviation in `r(sd)` and the skewness in `r(skewness)`, so we might type

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. jackknife sd=r(sd) skew=r(skewness), rclass: summarize mpg, detail
(running summarize on estimation sample)
Jackknife replications (74)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
........................
Jackknife results                                 Number of obs      =        74
                                                  Replications       =        74
      command:  summarize mpg, detail
           sd:  r(sd)
         skew:  r(skewness)
         n():  r(N)
------------------------------------------------------------------------------
             |             Jackknife
             |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
          sd |    5.785503   .6072509     9.53   0.000     4.575254    6.995753
        skew |     .9487176   .3367242     2.82   0.006     .2776272    1.619808
------------------------------------------------------------------------------
```

◁

Collecting coefficients

▷ Example 5

`jackknife` can also collect coefficients from estimation commands. For instance, using `auto.dta`, we might wish to obtain the jackknife standard errors of the coefficients from a regression in which we model the mileage of a car by its weight and trunk space. To do this, we could refer to the coefficients as `_b[weight]`, `_b[trunk]`, `_se[weight]`, and `_se[trunk]` in the *exp_list*, or we could simply use the extended expressions `_b`. In fact, `jackknife` assumes `_b` by default when used with estimation commands.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. jackknife: regress mpg weight trunk
(running regress on estimation sample)
Jackknife replications (74)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
........................
Linear regression                               Number of obs      =        74
                                                Replications       =        74
                                                F(   2,     73)    =     78.10
                                                Prob > F           =    0.0000
                                                R-squared          =    0.6543
                                                Adj R-squared      =    0.6446
                                                Root MSE           =    3.4492

------------------------------------------------------------------------------
             |             Jackknife
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0056527   .0010216    -5.53   0.000    -.0076887   -.0036167
       trunk |   -.096229   .1486236    -0.65   0.519    -.3924354    .1999773
       _cons |   39.68913   1.873324    21.19   0.000      35.9556    43.42266
------------------------------------------------------------------------------
```

If you are going to use `jackknife` to estimate standard errors of model coefficients, we recommend using the `vce(jackknife)` option when it is allowed with the estimation command; see [R] ***vce_option***.

```
. regress mpg weight trunk, vce(jackknife, nodots)
Linear regression                               Number of obs      =        74
                                                Replications       =        74
                                                F(   2,     73)    =     78.10
                                                Prob > F           =    0.0000
                                                R-squared          =    0.6543
                                                Adj R-squared      =    0.6446
                                                Root MSE           =    3.4492

◁

John Wilder Tukey (1915–2000) was born in Massachusetts. He studied chemistry at Brown and mathematics at Princeton and afterward worked at both Princeton and Bell Labs, as well as being involved in a great many government projects, consultancies, and committees. He made outstanding contributions to several areas of statistics, including time series, multiple comparisons, robust statistics, and exploratory data analysis. Tukey was extraordinarily energetic and inventive, not least in his use of terminology: he is credited with inventing the terms bit and software, in addition to ANOVA, boxplot, data analysis, hat matrix, jackknife, stem-and-leaf plot, trimming, and winsorizing, among many others. Tukey's direct and indirect impacts mark him as one of the greatest statisticians of all time.

Saved results

jknife saves the following in e():

Scalars

e(N)	sample size
e(N_reps)	number of complete replications
e(N_misreps)	number of incomplete replications
e(N_clust)	number of clusters
e(k_eq)	number of equations in e(b)
e(k_extra)	number of extra equations
e(k_exp)	number of expressions
e(k_eexp)	number of extended expressions (_b or _se)
e(df_r)	degrees of freedom

Macros

e(cmdname)	command name from *command*
e(cmd)	same as e(cmdname) or jackknife
e(command)	*command*
e(cmdline)	command as typed
e(prefix)	jackknife
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(cluster)	cluster variables
e(pseudo)	new variables containing pseudovalues
e(nfunction)	e(N), r(N), n() option, or empty
e(exp#)	expression for the #th statistic
e(mse)	from mse option
e(vce)	jackknife
e(vcetype)	title used to label Std. Err.
e(properties)	b V

Matrices

e(b)	observed statistics
e(b_jk)	jackknife estimates
e(V)	jackknife variance–covariance matrix
e(V_modelbased)	model-based variance

When *exp_list* is _b, jackknife will also carry forward most of the results already in e() from *command*.

Methods and formulas

jackknife is implemented as an ado-file.

Let $\widehat{\theta}$ be the observed value of the statistic, that is, the value of the statistic calculated using the original dataset. Let $\widehat{\theta}_{(j)}$ be the value of the statistic computed by leaving out the *j*th observation (or cluster); thus $j = 1, 2, \ldots, N$ identifies an individual observation (or cluster), and N is the total number of observations (or clusters). The *j*th pseudovalue is given by

$$\widehat{\theta}^*_j = \widehat{\theta}_{(j)} + N\{\widehat{\theta} - \widehat{\theta}_{(j)}\}$$

When the mse option is specified, the standard error is estimated as

$$\widehat{\mathrm{se}} = \left\{ \frac{N-1}{N} \sum_{j=1}^{N} (\widehat{\theta}_{(j)} - \widehat{\theta})^2 \right\}^{1/2}$$

and the jackknife estimate is

$$\bar{\theta}_{(.)} = \frac{1}{N}\sum_{j=1}^{N}\widehat{\theta}_{(j)}$$

Otherwise, the standard error is estimated as

$$\widehat{\mathrm{se}} = \left\{\frac{1}{N(N-1)}\sum_{j=1}^{N}(\widehat{\theta}^{*}_{j} - \bar{\theta}^{*})^{2}\right\}^{1/2} \qquad \bar{\theta}^{*} = \frac{1}{N}\sum_{j=1}^{N}\widehat{\theta}^{*}_{j}$$

where $\bar{\theta}^{*}$ is the jackknife estimate. The variance–covariance matrix is similarly computed.

Title

jackknife postestimation — Postestimation tools for jackknife

Description

The following postestimation commands are available after `jackknife`:

Command	Description
*`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
*`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
*`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
*`predict`	predictions, residuals, influence statistics, and other diagnostic measures
*`predictnl`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
*`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

*This postestimation command is allowed only if it may be used after *command*.

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

The syntax of `predict` (and whether `predict` is even allowed) following `jackknife` depends on the *command* used with `jackknife`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

kappa — Interrater agreement

Syntax

Interrater agreement, two unique raters

`kap` *varname*$_1$ *varname*$_2$ [*if*] [*in*] [*weight*] [`,` *options*]

Weights for weighting disagreements

`kapwgt` *wgtid* [`1` `\` `#` `1` [`\` `#` `#` `1` ...]]

Interrater agreement, nonunique raters, variables record ratings for each rater

`kap` *varname*$_1$ *varname*$_2$ *varname*$_3$ [...] [*if*] [*in*] [*weight*]

Interrater agreement, nonunique raters, variables record frequency of ratings

`kappa` *varlist* [*if*] [*in*]

options	Description
Main	
`tab`	display table of assessments
`wgt(`*wgtid*`)`	specify how to weight disagreements; see *Options* for alternatives
`absolute`	treat rating categories as absolute

`fweights` are allowed; see [U] **11.1.6 weight**.

Menu

kap: two unique raters

Statistics > Epidemiology and related > Other > Interrater agreement, two unique raters

kapwgt

Statistics > Epidemiology and related > Other > Define weights for the above (kap)

kap: nonunique raters

Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters

kappa

Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters with frequencies

Description

kap (first syntax) calculates the kappa-statistic measure of interrater agreement when there are two unique raters and two or more ratings.

kapwgt defines weights for use by kap in measuring the importance of disagreements.

kap (second syntax) and kappa calculate the kappa-statistic measure when there are two or more (nonunique) raters and two outcomes, more than two outcomes when the number of raters is fixed, and more than two outcomes when the number of raters varies. kap (second syntax) and kappa produce the same results; they merely differ in how they expect the data to be organized.

kap assumes that each observation is a subject. *varname*$_1$ contains the ratings by the first rater, *varname*$_2$ by the second rater, and so on.

kappa also assumes that each observation is a subject. The variables, however, record the frequencies with which ratings were assigned. The first variable records the number of times the first rating was assigned, the second variable records the number of times the second rating was assigned, and so on.

Options

Main

tab displays a tabulation of the assessments by the two raters.

wgt(*wgtid*) specifies that *wgtid* be used to weight disagreements. You can define your own weights by using kapwgt; wgt() then specifies the name of the user-defined matrix. For instance, you might define

```
. kapwgt mine 1 \ .8 1 \ 0 .8 1 \ 0 0 .8 1
```

and then

```
. kap rata ratb, wgt(mine)
```

Also, two prerecorded weights are available.

wgt(w) specifies weights $1 - |i - j|/(k - 1)$, where i and j index the rows and columns of the ratings by the two raters and k is the maximum number of possible ratings.

wgt(w2) specifies weights $1 - \{(i - j)/(k - 1)\}^2$.

absolute is relevant only if wgt() is also specified. The absolute option modifies how i, j, and k are defined and how corresponding entries are found in a user-defined weighting matrix. When absolute is not specified, i and j refer to the row and column index, not to the ratings themselves. Say that the ratings are recorded as $\{0, 1, 1.5, 2\}$. There are four ratings; $k = 4$, and i and j are still 1, 2, 3, and 4 in the formulas above. Index 3, for instance, corresponds to rating $= 1.5$. This system is convenient but can, with some data, lead to difficulties.

When absolute is specified, all ratings must be integers, and they must be coded from the set $\{1, 2, 3, \ldots\}$. Not all values need be used; integer values that do not occur are simply assumed to be unobserved.

Remarks

Remarks are presented under the following headings:

Two raters
More than two raters

The kappa-statistic measure of agreement is scaled to be 0 when the amount of agreement is what would be expected to be observed by chance and 1 when there is perfect agreement. For intermediate values, Landis and Koch (1977a, 165) suggest the following interpretations:

below 0.0	Poor
0.00–0.20	Slight
0.21–0.40	Fair
0.41–0.60	Moderate
0.61–0.80	Substantial
0.81–1.00	Almost perfect

Two raters

▷ Example 1

Consider the classification by two radiologists of 85 xeromammograms as normal, benign disease, suspicion of cancer, or cancer (a subset of the data from Boyd et al. [1982] and discussed in the context of kappa in Altman [1991, 403–405]).

```
. use http://www.stata-press.com/data/r12/rate2
(Altman p. 403)
. tabulate rada radb
```

Radiologist A's assessment	Radiologist B's assessment				
	normal	benign	suspect	cancer	Total
normal	21	12	0	0	33
benign	4	17	1	0	22
suspect	3	9	15	2	29
cancer	0	0	0	1	1
Total	28	38	16	3	85

Our dataset contains two variables: `rada`, radiologist A's assessment, and `radb`, radiologist B's assessment. Each observation is a patient.

We can obtain the kappa measure of interrater agreement by typing

```
. kap rada radb
```

Agreement	Expected Agreement	Kappa	Std. Err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

If each radiologist had made his determination randomly (but with probabilities equal to the overall proportions), we would expect the two radiologists to agree on 30.8% of the patients. In fact, they agreed on 63.5% of the patients, or 47.3% of the way between random agreement and perfect agreement. The amount of agreement indicates that we can reject the hypothesis that they are making their determinations randomly.

◁

▷ Example 2: Weighted kappa, prerecorded weight w

There is a difference between two radiologists disagreeing about whether a xeromammogram indicates cancer or the suspicion of cancer and disagreeing about whether it indicates cancer or is normal. The weighted kappa attempts to deal with this. `kap` provides two "prerecorded" weights, `w` and `w2`:

```
. kap rada radb, wgt(w)
Ratings weighted by:
   1.0000   0.6667   0.3333   0.0000
   0.6667   1.0000   0.6667   0.3333
   0.3333   0.6667   1.0000   0.6667
   0.0000   0.3333   0.6667   1.0000
            Expected
Agreement   Agreement     Kappa   Std. Err.         Z      Prob>Z
------------------------------------------------------------------
  86.67%      69.11%     0.5684      0.0788       7.22       0.0000
```

The `w` weights are given by $1 - |i-j|/(k-1)$, where i and j index the rows of columns of the ratings by the two raters and k is the maximum number of possible ratings. The weighting matrix is printed above the table. Here the rows and columns of the 4×4 matrix correspond to the ratings normal, benign, suspicious, and cancerous.

A weight of 1 indicates that an observation should count as perfect agreement. The matrix has 1s down the diagonals—when both radiologists make the same assessment, they are in agreement. A weight of, say, 0.6667 means that they are in two-thirds agreement. In our matrix, they get that score if they are "one apart"—one radiologist assesses cancer and the other is merely suspicious, or one is suspicious and the other says benign, and so on. An entry of 0.3333 means that they are in one-third agreement, or, if you prefer, two-thirds disagreement. That is the score attached when they are "two apart". Finally, they are in complete disagreement when the weight is zero, which happens only when they are three apart—one says cancer and the other says normal. ◁

▷ Example 3: Weighted kappa, prerecorded weight w2

The other prerecorded weight is `w2`, where the weights are given by $1 - \{(i-j)/(k-1)\}^2$:

```
. kap rada radb, wgt(w2)
Ratings weighted by:
   1.0000   0.8889   0.5556   0.0000
   0.8889   1.0000   0.8889   0.5556
   0.5556   0.8889   1.0000   0.8889
   0.0000   0.5556   0.8889   1.0000
            Expected
Agreement   Agreement     Kappa   Std. Err.         Z      Prob>Z
------------------------------------------------------------------
  94.77%      84.09%     0.6714      0.1079       6.22       0.0000
```

The `w2` weight makes the categories even more alike and is probably inappropriate here. ◁

▷ Example 4: Weighted kappa, user-defined weights

In addition to using prerecorded weights, we can define our own weights with the `kapwgt` command. For instance, we might feel that suspicious and cancerous are reasonably similar, that benign and normal are reasonably similar, but that the suspicious/cancerous group is nothing like the benign/normal group:

```
. kapwgt xm 1 \ .8 1 \ 0 0 1 \ 0 0 .8 1
. kapwgt xm
 1.0000
 0.8000 1.0000
 0.0000 0.0000 1.0000
 0.0000 0.0000 0.8000 1.0000
```

We name the weights `xm`, and after the weight name, we enter the lower triangle of the weighting matrix, using `\` to separate rows. We have four outcomes, so we continued entering numbers until we had defined the fourth row of the weighting matrix. If we type `kapwgt` followed by a name and nothing else, it shows us the weights recorded under that name. Satisfied that we have entered them correctly, we now use the weights to recalculate kappa:

```
. kap rada radb, wgt(xm)
Ratings weighted by:
   1.0000   0.8000   0.0000   0.0000
   0.8000   1.0000   0.0000   0.0000
   0.0000   0.0000   1.0000   0.8000
   0.0000   0.0000   0.8000   1.0000

            Expected
Agreement   Agreement      Kappa   Std. Err.         Z      Prob>Z
------------------------------------------------------------------
  80.47%      52.67%     0.5874      0.0865      6.79      0.0000
```

◁

❑ Technical note

In addition to using weights for weighting the differences in categories, you can specify Stata's traditional weights for weighting the data. In the examples above, we have 85 observations in our dataset—one for each patient. If we only knew the table of outcomes—that there were 21 patients rated normal by both radiologists, etc.—it would be easier to enter the table into Stata and work from it. The easiest way to enter the data is with `tabi`; see [R] **tabulate twoway**.

```
. tabi 21 12 0 0 \ 4 17 1 0 \ 3 9 15 2 \ 0 0 0 1, replace
```

row	col 1	2	3	4	Total
1	21	12	0	0	33
2	4	17	1	0	22
3	3	9	15	2	29
4	0	0	0	1	1
Total	28	38	16	3	85

Pearson chi2(9) = 77.8111 Pr = 0.000

`tabi` reported the Pearson χ^2 for this table, but we do not care about it. The important thing is that, with the `replace` option, `tabi` left the table in memory:

```
. list in 1/5
```

	row	col	pop
1.	1	1	21
2.	1	2	12
3.	1	3	0
4.	1	4	0
5.	2	1	4

The variable `row` is radiologist A's assessment, `col` is radiologist B's assessment, and `pop` is the number so assessed by both. Thus

```
. kap row col [freq=pop]
```

Agreement	Expected Agreement	Kappa	Std. Err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

If we are going to keep these data, the names `row` and `col` are not indicative of what the data reflect. We could type (see [U] **12.6 Dataset, variable, and value labels**)

```
. rename row rada
. rename col radb
. label var rada "Radiologist A's assessment"
. label var radb "Radiologist B's assessment"
. label define assess 1 normal 2 benign 3 suspect 4 cancer
. label values rada assess
. label values radb assess
. label data "Altman p. 403"
```

`kap`'s `tab` option, which can be used with or without weighted data, shows the table of assessments:

```
. kap rada radb [freq=pop], tab
```

Radiologist A's assessment	Radiologist B's assessment: normal	benign	suspect	cancer	Total
normal	21	12	0	0	33
benign	4	17	1	0	22
suspect	3	9	15	2	29
cancer	0	0	0	1	1
Total	28	38	16	3	85

Agreement	Expected Agreement	Kappa	Std. Err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

❑

❑ Technical note

You have data on individual patients. There are two raters, and the possible ratings are 1, 2, 3, and 4, but neither rater ever used rating 3:

```
. use http://www.stata-press.com/data/r12/rate2no3, clear
. tabulate ratera raterb
```

ratera	raterb 1	2	4	Total
1	6	4	3	13
2	5	3	3	11
4	1	1	26	28
Total	12	8	32	52

Here `kap` would determine that the ratings are from the set $\{1, 2, 4\}$ because those were the only values observed. `kap` would expect a user-defined weighting matrix to be 3×3, and if it were not, `kap` would issue an error message. In the formula-based weights, the calculation would be based on $i, j = 1, 2, 3$ corresponding to the three observed ratings $\{1, 2, 4\}$.

Specifying the `absolute` option would clarify that the ratings are 1, 2, 3, and 4; it just so happens that rating 3 was never assigned. If a user-defined weighting matrix were also specified, `kap` would expect it to be 4×4 or larger (larger because we can think of the ratings being 1, 2, 3, 4, 5, ... and it just so happens that ratings 5, 6, ... were never observed, just as rating 3 was not observed). In the formula-based weights, the calculation would be based on $i, j = 1, 2, 4$.

```
. kap ratera raterb, wgt(w)
Ratings weighted by:
   1.0000   0.5000   0.0000
   0.5000   1.0000   0.5000
   0.0000   0.5000   1.0000
             Expected
Agreement    Agreement      Kappa    Std. Err.          Z       Prob>Z
------------------------------------------------------------------------
  79.81%       57.17%      0.5285      0.1169        4.52       0.0000
. kap ratera raterb, wgt(w) absolute
Ratings weighted by:
   1.0000   0.6667   0.0000
   0.6667   1.0000   0.3333
   0.0000   0.3333   1.0000
             Expected
Agreement    Agreement      Kappa    Std. Err.          Z       Prob>Z
------------------------------------------------------------------------
  81.41%       55.08%      0.5862      0.1209        4.85       0.0000
```

If all conceivable ratings are observed in the data, specifying `absolute` makes no difference. For instance, if rater A assigns ratings $\{1, 2, 4\}$ and rater B assigns $\{1, 2, 3, 4\}$, the complete set of assigned ratings is $\{1, 2, 3, 4\}$, the same that `absolute` would specify. Without `absolute`, it makes no difference whether the ratings are coded $\{1, 2, 3, 4\}$, $\{0, 1, 2, 3\}$, $\{1, 7, 9, 100\}$, $\{0, 1, 1.5, 2.0\}$, or otherwise.

❑

More than two raters

For more than two raters, the mathematics are such that the two raters are not considered unique. For instance, if there are three raters, there is no assumption that the three raters who rate the first subject are the same as the three raters who rate the second. Although we call this the "more than two raters" case, it can be used with two raters when the raters' identities vary.

The nonunique rater case can be usefully broken down into three subcases: 1) there are two possible ratings, which we will call positive and negative; 2) there are more than two possible ratings, but the number of raters per subject is the same for all subjects; and 3) there are more than two possible ratings, and the number of raters per subject varies. `kappa` handles all these cases. To emphasize that there is no assumption of constant identity of raters across subjects, the variables specified contain counts of the number of raters rating the subject into a particular category.

Jacob Cohen (1923–1998) was born in New York City. After studying psychology at City College of New York and New York University, he worked as a medical psychologist until 1959 when he became a full professor in the Department of Psychology at New York University. He made many contributions to research methods, including the kappa measure. He persistently emphasized the value of multiple regression and the importance of power and of measuring effects rather than testing significance.

▷ Example 5: Two ratings

Fleiss, Levin, and Paik (2003, 612) offers the following hypothetical ratings by different sets of raters on 25 subjects:

Subject	No. of raters	No. of pos. ratings	Subject	No. of raters	No. of pos. ratings
1	2	2	14	4	3
2	2	0	15	2	0
3	3	2	16	2	2
4	4	3	17	3	1
5	3	3	18	2	1
6	4	1	19	4	1
7	3	0	20	5	4
8	5	0	21	3	2
9	2	0	22	4	0
10	4	4	23	3	0
11	5	5	24	3	3
12	3	3	25	2	2
13	4	4			

We have entered these data into Stata, and the variables are called `subject`, `raters`, and `pos`. `kappa`, however, requires that we specify variables containing the number of positive ratings and negative ratings, that is, `pos` and `raters-pos`:

```
. use http://www.stata-press.com/data/r12/p612
. gen neg = raters-pos
. kappa pos neg
Two-outcomes, multiple raters:
        Kappa        Z        Prob>Z
-------------------------------------
       0.5415     5.28       0.0000
```

We would have obtained the same results if we had typed `kappa neg pos`.

◁

▷ Example 6: More than two ratings, constant number of raters, kappa

Each of 10 subjects is rated into one of three categories by five raters (Fleiss, Levin, and Paik 2003, 615):

```
. use http://www.stata-press.com/data/r12/p615, clear
. list
```

	subject	cat1	cat2	cat3
1.	1	1	4	0
2.	2	2	0	3
3.	3	0	0	5
4.	4	4	0	1
5.	5	3	0	2
6.	6	1	4	0
7.	7	5	0	0
8.	8	0	4	1
9.	9	1	0	4
10.	10	3	0	2

We obtain the kappa statistic:

```
. kappa cat1-cat3
```

Outcome	Kappa	Z	Prob>Z
cat1	0.2917	2.92	0.0018
cat2	0.6711	6.71	0.0000
cat3	0.3490	3.49	0.0002
combined	0.4179	5.83	0.0000

The first part of the output shows the results of calculating kappa for each of the categories separately against an amalgam of the remaining categories. For instance, the `cat1` line is the two-rating kappa, where positive is `cat1` and negative is `cat2` or `cat3`. The test statistic, however, is calculated differently (see *Methods and formulas*). The combined kappa is the appropriately weighted average of the individual kappas. There is considerably less agreement about the rating of subjects into the first category than there is for the second.

◁

▷ Example 7: More than two ratings, constant number of raters, kap

Now suppose that we have the same data as in the previous example but that the data are organized differently:

```
. use http://www.stata-press.com/data/r12/p615b
. list
```

	subject	rater1	rater2	rater3	rater4	rater5
1.	1	1	2	2	2	2
2.	2	1	1	3	3	3
3.	3	3	3	3	3	3
4.	4	1	1	1	1	3
5.	5	1	1	1	3	3
6.	6	1	2	2	2	2
7.	7	1	1	1	1	1
8.	8	2	2	2	2	3
9.	9	1	3	3	3	3
10.	10	1	1	1	3	3

Here we would use `kap` rather than `kappa` because the variables record ratings for each rater.

```
. kap rater1 rater2 rater3 rater4 rater5
There are 5 raters per subject:
```

Outcome	Kappa	Z	Prob>Z
1	0.2917	2.92	0.0018
2	0.6711	6.71	0.0000
3	0.3490	3.49	0.0002
combined	0.4179	5.83	0.0000

It does not matter which rater is which when there are more than two raters.

◁

▷ Example 8: More than two ratings, varying number of raters, kappa

In this unfortunate case, kappa can be calculated, but there is no test statistic for testing against $\kappa > 0$. We do nothing differently—`kappa` calculates the total number of raters for each subject, and, if it is not a constant, `kappa` suppresses the calculation of test statistics.

```
. use http://www.stata-press.com/data/r12/rvary
. list
```

	subject	cat1	cat2	cat3
1.	1	1	3	0
2.	2	2	0	3
3.	3	0	0	5
4.	4	4	0	1
5.	5	3	0	2
6.	6	1	4	0
7.	7	5	0	0
8.	8	0	4	1
9.	9	1	0	2
10.	10	3	0	2

```
. kappa cat1-cat3
```

Outcome	Kappa	Z	Prob>Z
cat1	0.2685	.	.
cat2	0.6457	.	.
cat3	0.2938	.	.
combined	0.3816	.	.

```
Note:  number of ratings per subject vary; cannot calculate test
       statistics.
```

◁

▷ Example 9: More than two ratings, varying number of raters, kap

This case is similar to the previous example, but the data are organized differently:

```
. use http://www.stata-press.com/data/r12/rvary2
. list
```

	subject	rater1	rater2	rater3	rater4	rater5
1.	1	1	2	2	.	2
2.	2	1	1	3	3	3
3.	3	3	3	3	3	3
4.	4	1	1	1	1	3
5.	5	1	1	1	3	3
6.	6	1	2	2	2	2
7.	7	1	1	1	1	1
8.	8	2	2	2	2	3
9.	9	1	3	.	.	3
10.	10	1	1	1	3	3

Here we specify `kap` instead of `kappa` because the variables record ratings for each rater.

```
. kap rater1-rater5
There are between 3 and 5 (median = 5.00) raters per subject:
```

Outcome	Kappa	Z	Prob>Z
1	0.2685	.	.
2	0.6457	.	.
3	0.2938	.	.
combined	0.3816	.	.

```
Note:  number of ratings per subject vary; cannot calculate test
       statistics.
```

◁

Saved results

kap and kappa save the following in r():

Scalars

r(N)	number of subjects (kap only)	r(kappa)	kappa
r(prop_o)	observed proportion of agreement (kap only)	r(z)	z statistic
r(prop_e)	expected proportion of agreement (kap only)	r(se)	standard error for kappa statistic

Methods and formulas

kap, kapwgt, and kappa are implemented as ado-files.

The kappa statistic was first proposed by Cohen (1960). The generalization for weights reflecting the relative seriousness of each possible disagreement is due to Cohen (1968). The analysis-of-variance approach for $k = 2$ and $m \geq 2$ is due to Landis and Koch (1977b). See Altman (1991, 403–409) or Dunn (2000, chap. 2) for an introductory treatment and Fleiss, Levin, and Paik (2003, chap. 18) for a more detailed treatment. All formulas below are as presented in Fleiss, Levin, and Paik (2003). Let m be the number of raters, and let k be the number of rating outcomes.

Methods and formulas are presented under the following headings:

kap: $m = 2$
kappa: $m > 2$, $k = 2$
kappa: $m > 2$, $k > 2$

kap: m = 2

Define w_{ij} ($i = 1, \ldots, k$ and $j = 1, \ldots, k$) as the weights for agreement and disagreement (wgt()), or, if the data are not weighted, define $w_{ii} = 1$ and $w_{ij} = 0$ for $i \neq j$. If wgt(w) is specified, $w_{ij} = 1 - |i - j|/(k - 1)$. If wgt(w2) is specified, $w_{ij} = 1 - \{(i - j)/(k - 1)\}^2$.

The observed proportion of agreement is

$$p_o = \sum_{i=1}^{k} \sum_{j=1}^{k} w_{ij} p_{ij}$$

where p_{ij} is the fraction of ratings i by the first rater and j by the second. The expected proportion of agreement is

$$p_e = \sum_{i=1}^{k} \sum_{j=1}^{k} w_{ij} p_{i\cdot} p_{\cdot j}$$

where $p_{i\cdot} = \sum_j p_{ij}$ and $p_{\cdot j} = \sum_i p_{ij}$.

Kappa is given by $\widehat{\kappa} = (p_o - p_e)/(1 - p_e)$.

The standard error of $\widehat{\kappa}$ for testing against 0 is

$$\widehat{s}_0 = \frac{1}{(1 - p_e)\sqrt{n}} \left(\left[\sum_i \sum_j p_{i\cdot} p_{\cdot j} \{ w_{ij} - (\overline{w}_{i\cdot} + \overline{w}_{\cdot j}) \}^2 \right] - p_e^2 \right)^{1/2}$$

where n is the number of subjects being rated, $\overline{w}_{i\cdot} = \sum_j p_{\cdot j} w_{ij}$, and $\overline{w}_{\cdot j} = \sum_i p_{i\cdot} w_{ij}$. The test statistic $Z = \widehat{\kappa}/\widehat{s}_0$ is assumed to be distributed $N(0, 1)$.

kappa: m > 2, k = 2

Each subject i, $i = 1, \ldots, n$, is found by x_i of m_i raters to be positive (the choice as to what is labeled positive is arbitrary).

The overall proportion of positive ratings is $\overline{p} = \sum_i x_i/(n\overline{m})$, where $\overline{m} = \sum_i m_i/n$. The between-subjects mean square is (approximately)

$$B = \frac{1}{n}\sum_i \frac{(x_i - m_i\overline{p})^2}{m_i}$$

and the within-subject mean square is

$$W = \frac{1}{n(\overline{m}-1)}\sum_i \frac{x_i(m_i - x_i)}{m_i}$$

Kappa is then defined as

$$\widehat{\kappa} = \frac{B - W}{B + (\overline{m}-1)W}$$

The standard error for testing against 0 (Fleiss and Cuzick 1979) is approximately equal to and is calculated as

$$\widehat{s}_0 = \frac{1}{(\overline{m}-1)\sqrt{n\overline{m}_H}}\left\{2(\overline{m}_H - 1) + \frac{(\overline{m} - \overline{m}_H)(1 - 4\overline{pq})}{\overline{m}\overline{p}\overline{q}}\right\}^{1/2}$$

where $\overline{m}_H$ is the harmonic mean of m_i and $\overline{q} = 1 - \overline{p}$.

The test statistic $Z = \widehat{\kappa}/\widehat{s}_0$ is assumed to be distributed $N(0, 1)$.

kappa: m > 2, k > 2

Let x_{ij} be the number of ratings on subject i, $i = 1, \ldots, n$, into category j, $j = 1, \ldots, k$. Define $\overline{p}_j$ as the overall proportion of ratings in category j, $\overline{q}_j = 1 - \overline{p}_j$, and let $\widehat{\kappa}_j$ be the kappa statistic given above for $k = 2$ when category j is compared with the amalgam of all other categories. Kappa is

$$\overline{\kappa} = \frac{\sum_j \overline{p}_j\overline{q}_j\widehat{\kappa}_j}{\sum_j \overline{p}_j\overline{q}_j}$$

(Landis and Koch 1977b). In the case where the number of raters per subject, $\sum_j x_{ij}$, is a constant m for all i, Fleiss, Nee, and Landis (1979) derived the following formulas for the approximate standard errors. The standard error for testing $\widehat{\kappa}_j$ against 0 is

$$\widehat{s}_j = \left\{\frac{2}{nm(m-1)}\right\}^{1/2}$$

and the standard error for testing $\overline{\kappa}$ is

$$\overline{s} = \frac{\sqrt{2}}{\sum_j \overline{p}_j \overline{q}_j \sqrt{nm(m-1)}} \left\{ \left(\sum_j \overline{p}_j \overline{q}_j \right)^2 - \sum_j \overline{p}_j \overline{q}_j (\overline{q}_j - \overline{p}_j) \right\}^{1/2}$$

Title

kdensity — Univariate kernel density estimation

Syntax

`kdensity` *varname* [*if*] [*in*] [*weight*] [, *options*]

options	Description
Main	
`kernel(`*kernel*`)`	specify kernel function; default is `kernel(epanechnikov)`
`bwidth(#)`	half-width of kernel
`generate(`*newvar*$_x$ *newvar*$_d$`)`	store the estimation points in *newvar*$_x$ and the density estimate in *newvar*$_d$
`n(#)`	estimate density using # points; default is min(N, 50)
`at(`*var*$_x$`)`	estimate density using the values specified by *var*$_x$
`nograph`	suppress graph
Kernel plot	
cline_options	affect rendition of the plotted kernel density estimate
Density plots	
`normal`	add normal density to the graph
`normopts(`*cline_options*`)`	affect rendition of normal density
`student(#)`	add Student's t density with # degrees of freedom to the graph
`stopts(`*cline_options*`)`	affect rendition of the Student's t density
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

kernel	Description
`epanechnikov`	Epanechnikov kernel function; the default
`epan2`	alternative Epanechnikov kernel function
`biweight`	biweight kernel function
`cosine`	cosine trace kernel function
`gaussian`	Gaussian kernel function
`parzen`	Parzen kernel function
`rectangle`	rectangle kernel function
`triangle`	triangle kernel function

`fweights`, `aweights`, and `iweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Nonparametric analysis > Kernel density estimation

Description

`kdensity` produces kernel density estimates and graphs the result.

Options

Main

`kernel(`*kernel*`)` specifies the kernel function for use in calculating the kernel density estimate. The default kernel is the Epanechnikov kernel (`epanechnikov`).

`bwidth(#)` specifies the half-width of the kernel, the width of the density window around each point. If `bwidth()` is not specified, the "optimal" width is calculated and used. The optimal width is the width that would minimize the mean integrated squared error if the data were Gaussian and a Gaussian kernel were used, so it is not optimal in any global sense. In fact, for multimodal and highly skewed densities, this width is usually too wide and oversmooths the density (Silverman 1992).

`generate(`*newvar*$_x$ *newvar*$_d$`)` stores the results of the estimation. *newvar*$_x$ will contain the points at which the density is estimated. *newvar*$_d$ will contain the density estimate.

`n(#)` specifies the number of points at which the density estimate is to be evaluated. The default is $\min(N, 50)$, where N is the number of observations in memory.

`at(`*var*$_x$`)` specifies a variable that contains the values at which the density should be estimated. This option allows you to more easily obtain density estimates for different variables or different subsamples of a variable and then overlay the estimated densities for comparison.

`nograph` suppresses the graph. This option is often used with the `generate()` option.

Kernel plot

cline_options affect the rendition of the plotted kernel density estimate. See [G-3] ***cline_options***.

Density plots

`normal` requests that a normal density be overlaid on the density estimate for comparison.

`normopts(`*cline_options*`)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-3] ***cline_options***.

`student(#)` specifies that a Student's t density with # degrees of freedom be overlaid on the density estimate for comparison.

`stopts(`*cline_options*`)` affects the rendition of the Student's t density. See [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Kernel density estimators approximate the density $f(x)$ from observations on x. Histograms do this, too, and the histogram itself is a kind of kernel density estimate. The data are divided into nonoverlapping intervals, and counts are made of the number of data points within each interval. Histograms are bar graphs that depict these frequency counts—the bar is centered at the midpoint of each interval—and its height reflects the average number of data points in the interval.

In more general kernel density estimates, the range is still divided into intervals, and estimates of the density at the center of intervals are produced. One difference is that the intervals are allowed to overlap. We can think of sliding the interval—called a window—along the range of the data and collecting the center-point density estimates. The second difference is that, rather than merely counting the number of observations in a window, a kernel density estimator assigns a weight between 0 and 1—based on the distance from the center of the window—and sums the weighted values. The function that determines these weights is called the kernel.

Kernel density estimates have the advantages of being smooth and of being independent of the choice of origin (corresponding to the location of the bins in a histogram).

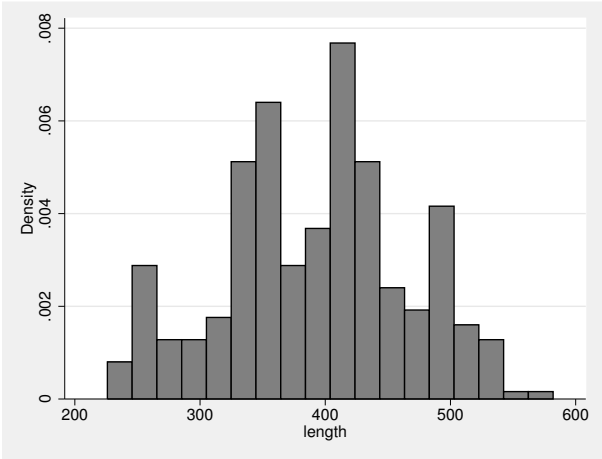
See Salgado-Ugarte, Shimizu, and Taniuchi (1993) and Fox (1990) for discussions of kernel density estimators that stress their use as exploratory data-analysis tools.

Cox (2007) gives a lucid introductory tutorial on kernel density estimation with several Stata produced examples. He provides tips and tricks for working with skewed or bounded distributions and applying the same techniques to estimate the intensity function of a point process.

▷ Example 1: Histogram and kernel density estimate

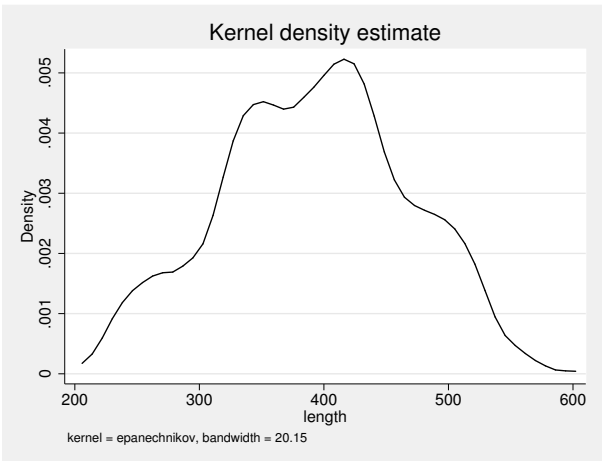
Goeden (1978) reports data consisting of 316 length observations of coral trout. We wish to investigate the underlying density of the lengths. To begin on familiar ground, we might draw a histogram. In [R] **histogram**, we suggest setting the bins to $\min(\sqrt{n}, 10 \cdot \log_{10} n)$, which for $n = 316$ is roughly 18:

```
. use http://www.stata-press.com/data/r12/trocolen
. histogram length, bin(18)
(bin=18, start=226, width=19.777778)
```



The kernel density estimate, on the other hand, is smooth.

```
. kdensity length
```



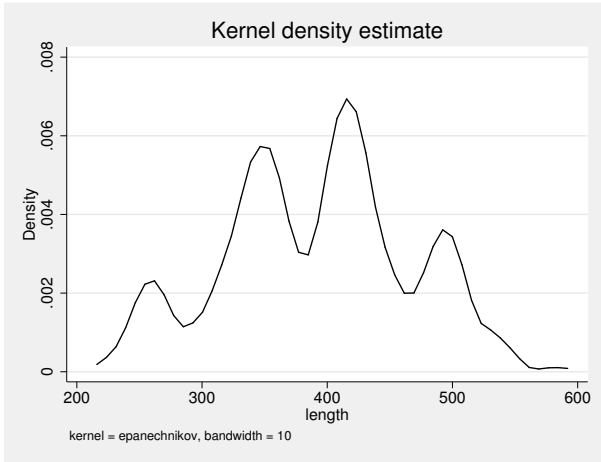
Kernel density estimators are, however, sensitive to an assumption, just as are histograms. In histograms, we specify a number of bins. For kernel density estimators, we specify a width. In the graph above, we used the default width. `kdensity` is smarter than `twoway histogram` in that its default width is not a fixed constant. Even so, the default width is not necessarily best.

`kdensity` saves the width in the returned scalar `bwidth`, so typing `display r(bwidth)` reveals it. Doing this, we discover that the width is approximately 20.

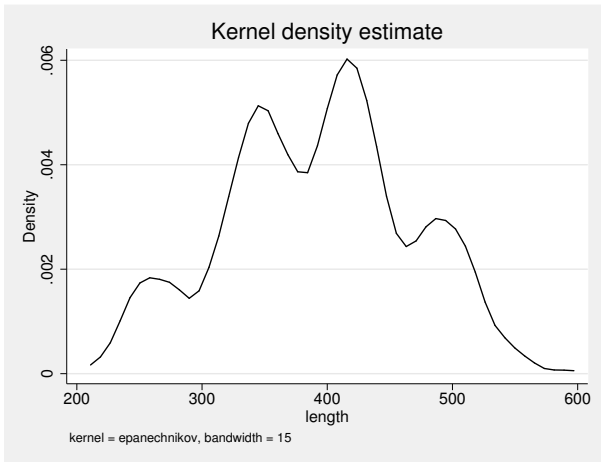
Widths are similar to the inverse of the number of bins in a histogram in that smaller widths provide more detail. The units of the width are the units of x, the variable being analyzed. The width is specified as a half-width, meaning that the kernel density estimator with half-width 20 corresponds to sliding a window of size 40 across the data.

We can specify half-widths for ourselves by using the `bwidth()` option. Smaller widths do not smooth the density as much:

```
. kdensity length, bwidth(10)
```



```
. kdensity length, bwidth(15)
```



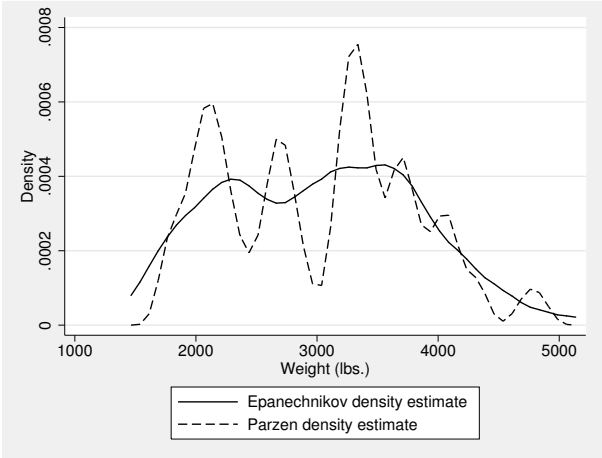
◁

▷ Example 2: Different kernels can produce different results

When widths are held constant, different kernels can produce surprisingly different results. This is really an attribute of the kernel and width combination; for a given width, some kernels are more sensitive than others at identifying peaks in the density estimate.

We can see this when using a dataset with lots of peaks. In the automobile dataset, we characterize the density of `weight`, the weight of the vehicles. Below we compare the Epanechnikov and Parzen kernels.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. kdensity weight, kernel(epanechnikov) nograph generate(x epan)
. kdensity weight, kernel(parzen) nograph generate(x2 parzen)
. label var epan "Epanechnikov density estimate"
. label var parzen "Parzen density estimate"
. line epan parzen x, sort ytitle(Density) legend(cols(1))
```

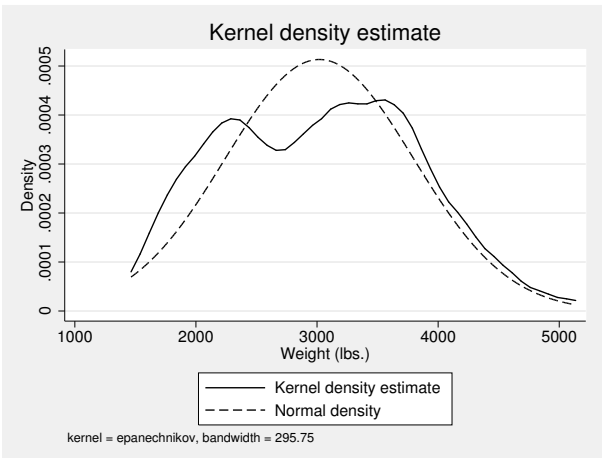


We did not specify a width, so we obtained the default width. That width is not a function of the selected kernel, but of the data. See *Methods and formulas* for the calculation of the optimal width.

Example 3: Density with overlaid normal density

In examining the density estimates, we may wish to overlay a normal density or a Student's t density for comparison. Using automobile weights, we can get an idea of the distance from normality by using the `normal` option.

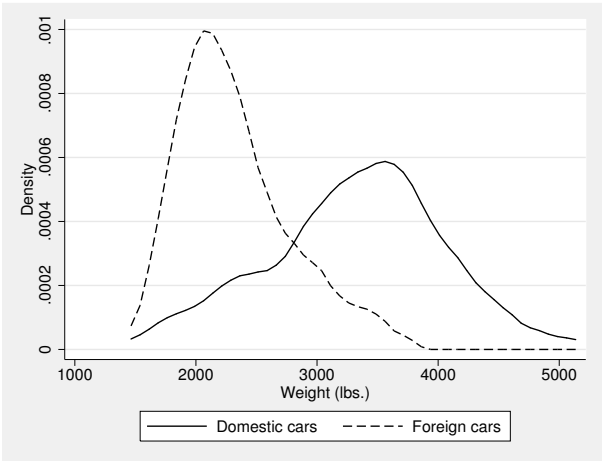
```
. kdensity weight, kernel(epanechnikov) normal
```



▷ Example 4: Compare two densities

We also may want to compare two or more densities. In this example, we will compare the density estimates of the weights for the foreign and domestic cars.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. kdensity weight, nograph generate(x fx)
. kdensity weight if foreign==0, nograph generate(fx0) at(x)
. kdensity weight if foreign==1, nograph generate(fx1) at(x)
. label var fx0 "Domestic cars"
. label var fx1 "Foreign cars"
. line fx0 fx1 x, sort ytitle(Density)
```



◁

❑ Technical note

Although all the examples we included had densities of less than 1, the density may exceed 1.

The probability density $f(x)$ of a continuous variable, x, has the units and dimensions of the reciprocal of x. If x is measured in meters, $f(x)$ has units $1/$meter. Thus the density is not measured on a probability scale, so it is possible for $f(x)$ to exceed 1.

To see this, think of a uniform density on the interval 0 to 1. The area under the density curve is 1: this is the product of the density, which is constant at 1, and the range, which is 1. If the variable is then transformed by doubling, the area under the curve remains 1 and is the product of the density, constant at 0.5, and the range, which is 2. Conversely, if the variable is transformed by halving, the area under the curve also remains at 1 and is the product of the density, constant at 2, and the range, which is 0.5. (Strictly, the range is measured in certain units, and the density is measured in the reciprocal of those units, so the units cancel on multiplication.)

❑

Saved results

kdensity saves the following in r():

Scalars
- r(bwidth) kernel bandwidth
- r(n) number of points at which the estimate was evaluated
- r(scale) density bin width

Macros
- r(kernel) name of kernel

Methods and formulas

kdensity is implemented as an ado-file.

A kernel density estimate is formed by summing the weighted values calculated with the kernel function K, as in

$$\widehat{f}_K = \frac{1}{qh}\sum_{i=1}^{n} w_i K\left(\frac{x - X_i}{h}\right)$$

where $q = \sum_i w_i$ if weights are frequency weights (fweight) or analytic weights (aweight), and $q = 1$ if weights are importance weights (iweights). Analytic weights are rescaled so that $\sum_i w_i = n$ (see [U] **11 Language syntax**). If weights are not used, then $w_i = 1$, for $i = 1, \ldots, n$. kdensity includes seven different kernel functions. The Epanechnikov is the default function if no other kernel is specified and is the most efficient in minimizing the mean integrated squared error.

Kernel	Formula	
Biweight	$K[z] = \begin{cases} \frac{15}{16}(1-z^2)^2 \\ 0 \end{cases}$	if $\lvert z\rvert < 1$ otherwise
Cosine	$K[z] = \begin{cases} 1+\cos(2\pi z) \\ 0 \end{cases}$	if $\lvert z\rvert < 1/2$ otherwise
Epanechnikov	$K[z] = \begin{cases} \frac{3}{4}(1-\frac{1}{5}z^2)/\sqrt{5} \\ 0 \end{cases}$	if $\lvert z\rvert < \sqrt{5}$ otherwise
Epan2	$K[z] = \begin{cases} \frac{3}{4}(1-z^2) \\ 0 \end{cases}$	if $\lvert z\rvert < 1$ otherwise
Gaussian	$K[z] = \frac{1}{\sqrt{2\pi}}e^{-z^2/2}$	
Parzen	$K[z] = \begin{cases} \frac{4}{3} - 8z^2 + 8\lvert z\rvert^3 \\ 8(1-\lvert z\rvert)^3/3 \\ 0 \end{cases}$	if $\lvert z\rvert \le 1/2$ if $1/2 < \lvert z\rvert \le 1$ otherwise
Rectangular	$K[z] = \begin{cases} 1/2 \\ 0 \end{cases}$	if $\lvert z\rvert < 1$ otherwise
Triangular	$K[z] = \begin{cases} 1-\lvert z\rvert \\ 0 \end{cases}$	if $\lvert z\rvert < 1$ otherwise

From the definitions given in the table, we can see that the choice of h will drive how many values are included in estimating the density at each point. This value is called the *window width* or *bandwidth*. If the window width is not specified, it is determined as

$$m = \min\left(\sqrt{\text{variance}_x},\ \frac{\text{interquartile range}_x}{1.349}\right)$$
$$h = \frac{0.9m}{n^{1/5}}$$

where x is the variable for which we wish to estimate the kernel and n is the number of observations.

Most researchers agree that the choice of kernel is not as important as the choice of bandwidth. There is a great deal of literature on choosing bandwidths under various conditions; see, for example, Parzen (1962) or Tapia and Thompson (1978). Also see Newton (1988) for a comparison with sample spectral density estimation in time-series applications.

Acknowledgments

We gratefully acknowledge the previous work by Isaías H. Salgado-Ugarte of Universidad Nacional Autónoma de México, and Makoto Shimizu and Toru Taniuchi of the University of Tokyo; see Salgado-Ugarte, Shimizu, and Taniuchi (1993). Their article provides a good overview of the subject of univariate kernel density estimation and presents arguments for its use in exploratory data analysis.

Title

ksmirnov — Kolmogorov–Smirnov equality-of-distributions test

Syntax

One-sample Kolmogorov–Smirnov test

```
ksmirnov varname = exp [if] [in]
```

Two-sample Kolmogorov–Smirnov test

```
ksmirnov varname [if] [in], by(groupvar) [ exact ]
```

Menu

one-sample

Statistics > Nonparametric analysis > Tests of hypotheses > One-sample Kolmogorov-Smirnov test

two-sample

Statistics > Nonparametric analysis > Tests of hypotheses > Two-sample Kolmogorov-Smirnov test

Description

`ksmirnov` performs one- and two-sample Kolmogorov–Smirnov tests of the equality of distributions. In the first syntax, *varname* is the variable whose distribution is being tested, and *exp* must evaluate to the corresponding (theoretical) cumulative. In the second syntax, *groupvar* must take on two distinct values. The distribution of *varname* for the first value of *groupvar* is compared with that of the second value.

When testing for normality, please see [R] **sktest** and [R] **swilk**.

Options for two-sample test

Main

`by(`*groupvar*`)` is required. It specifies a binary variable that identifies the two groups.

`exact` specifies that the exact p-value be computed. This may take a long time if $n > 50$.

Remarks

▷ Example 1: Two-sample test

Say that we have data on `x` that resulted from two different experiments, labeled as `group==1` and `group==2`. Our data contain

```
. use http://www.stata-press.com/data/r12/ksxmpl
. list
```

	group	x
1.	2	2
2.	1	0
3.	2	3
4.	1	4
5.	1	5
6.	2	8
7.	2	10

We wish to use the two-sample Kolmogorov–Smirnov test to determine if there are any differences in the distribution of `x` for these two groups:

```
. ksmirnov x, by(group)
Two-sample Kolmogorov-Smirnov test for equality of distribution functions
 Smaller group       D       P-value  Corrected
 ------------------------------------------------
 1:                   0.5000    0.424
 2:                  -0.1667    0.909
 Combined K-S:        0.5000    0.785      0.735
```

The first line tests the hypothesis that `x` for group 1 contains *smaller* values than for group 2. The largest difference between the distribution functions is 0.5. The approximate p-value for this is 0.424, which is not significant.

The second line tests the hypothesis that `x` for group 1 contains *larger* values than for group 2. The largest difference between the distribution functions in this direction is 0.1667. The approximate p-value for this small difference is 0.909.

Finally, the approximate p-value for the combined test is 0.785, corrected to 0.735. The p-values `ksmirnov` calculates are based on the asymptotic distributions derived by Smirnov (1933). These approximations are not good for small samples ($n < 50$). They are too conservative—real p-values tend to be substantially smaller. We have also included a less conservative approximation for the nondirectional hypothesis based on an empirical continuity correction—the 0.735 reported in the third column.

That number, too, is only an approximation. An exact value can be calculated using the `exact` option:

```
. ksmirnov x, by(group) exact
Two-sample Kolmogorov-Smirnov test for equality of distribution functions
 Smaller group       D       P-value      Exact
 ------------------------------------------------
 1:                   0.5000    0.424
 2:                  -0.1667    0.909
 Combined K-S:        0.5000    0.785      0.657
```

◁

▷ Example 2: One-sample test

Let's now test whether `x` in the example above is distributed normally. Kolmogorov–Smirnov is not a particularly powerful test in testing for normality, and we do not endorse such use of it; see [R] **sktest** and [R] **swilk** for better tests.

In any case, we will test against a normal distribution with the same mean and standard deviation:

```
. summarize x
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
           x |          7    4.571429    3.457222           0         10

. ksmirnov x = normal((x-4.571429)/3.457222)

One-sample Kolmogorov-Smirnov test against theoretical distribution
           normal((x-4.571429)/3.457222)
 Smaller group       D       P-value  Corrected
 ------------------------------------------------
 x:                  0.1650    0.683
 Cumulative:        -0.1250    0.803
 Combined K-S:       0.1650    0.991      0.978
```

Because Stata has no way of knowing that we based this calculation on the calculated mean and standard deviation of `x`, the test statistics will be slightly conservative in addition to being approximations. Nevertheless, they clearly indicate that the data cannot be distinguished from normally distributed data.

In general, the Kolmogorov–Smirnov test (Kolmogorov 1933; Smirnov 1933; also see Conover [1999], 428–465) is not very powerful against differences in the tails of distributions. In return for this, it is fairly powerful for alternative hypotheses that involve lumpiness or clustering in the data.

The directional hypotheses are evaluated with the statistics

$$D^+ = \max_x \Big\{ F(x) - G(x) \Big\}$$
$$D^- = \min_x \Big\{ F(x) - G(x) \Big\}$$

where $F(x)$ and $G(x)$ are the empirical distribution functions for the sample being compared. The combined statistic is

$$D = \max\Big(|D^+|\,,\, |D^-| \Big)$$

The p-value for this statistic may be obtained by evaluating the asymptotic limiting distribution. Let m be the sample size for the first sample, and let n be the sample size for the second sample. Smirnov (1933) shows that

$$\lim_{m,n\to\infty} \Pr\left\{\sqrt{mn/(m+n)}D_{m,n} \le z\right\} = 1 - 2\sum_{i=1}^{\infty}(-1)^{i-1}\exp\left(-2i^2z^2\right)$$

The first five terms form the approximation P_a used by Stata. The exact p-value is calculated by a counting algorithm; see Gibbons and Chakraborti (2011, 236–238). A corrected p-value was obtained by modifying the asymptotic p-value by using a numerical approximation technique:

$$Z = \Phi^{-1}(P_a) + 1.04/\min(m,n) + 2.09/\max(m,n) - 1.35/\sqrt{mn/(m+n)}$$
$$p\text{-value} = \Phi(Z)$$

where $\Phi(\cdot)$ is the cumulative normal distribution.

Andrei Nikolayevich Kolmogorov (1903–1987), of Russia, was one of the great mathematicians of the twentieth century, making outstanding contributions in many different branches, including set theory, measure theory, probability and statistics, approximation theory, functional analysis, classical dynamics, and theory of turbulence. He was a faculty member at Moscow State University for more than 60 years.

Nikolai Vasilyevich Smirnov (1900–1966) was a Russian statistician whose work included contributions in nonparametric statistics, order statistics, and goodness of fit. After army service and the study of philosophy and philology, he turned to mathematics and eventually rose to be head of mathematical statistics at the Steklov Mathematical Institute in Moscow.

Title

kwallis — Kruskal–Wallis equality-of-populations rank test

Syntax

`kwallis` *varname* [*if*] [*in*] , `by(`*groupvar*`)`

Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kruskal-Wallis rank test

Description

`kwallis` tests the hypothesis that several samples are from the same population. In the syntax diagram above, *varname* refers to the variable recording the outcome, and *groupvar* refers to the variable denoting the population. `by()` is required.

Option

`by(`*groupvar*`)` is required. It specifies a variable that identifies the groups.

Remarks

▷ Example 1

We have data on the 50 states. The data contain the median age of the population, `medage`, and the region of the country, `region`, for each state. We wish to test for the equality of the median age distribution across all four regions simultaneously:

```
. use http://www.stata-press.com/data/r12/census
(1980 Census data by state)
. kwallis medage, by(region)
Kruskal-Wallis equality-of-populations rank test
```

region	Obs	Rank Sum
NE	9	376.50
N Cntrl	12	294.00
South	16	398.00
West	13	206.50

```
chi-squared =    17.041 with 3 d.f.
probability =     0.0007
chi-squared with ties =    17.062 with 3 d.f.
probability =     0.0007
```

From the output, we see that we can reject the hypothesis that the populations are the same at any level below 0.07%. ◁

Saved results

`kwallis` saves the following in `r()`:

Scalars

`r(df)`	degrees of freedom
`r(chi2)`	χ^2
`r(chi2_adj)`	χ^2 adjusted for ties

Methods and formulas

`kwallis` is implemented as an ado-file.

The Kruskal–Wallis test (Kruskal and Wallis 1952, 1953; also see Altman [1991, 213–215]; Conover [1999, 288–297]; and Riffenburgh [2005, 287–291]) is a multiple-sample generalization of the two-sample Wilcoxon (also called Mann–Whitney) rank sum test (Wilcoxon 1945; Mann and Whitney 1947). Samples of sizes n_j, $j = 1, \ldots, m$, are combined and ranked in ascending order of magnitude. Tied values are assigned the average ranks. Let n denote the overall sample size, and let $R_j = \sum_{i=1}^{n_j} R(X_{ji})$ denote the sum of the ranks for the jth sample. The Kruskal–Wallis one-way analysis-of-variance test, H, is defined as

$$H = \frac{1}{S^2}\left\{\sum_{j=1}^{m}\frac{R_j^2}{n_j} - \frac{n(n+1)^2}{4}\right\}$$

where

$$S^2 = \frac{1}{n-1}\left\{\sum_{\text{all ranks}} R(X_{ji})^2 - \frac{n(n+1)^2}{4}\right\}$$

If there are no ties, this equation simplifies to

$$H = \frac{12}{n(n+1)}\sum_{j=1}^{m}\frac{R_j^2}{n_j} - 3(n+1)$$

The sampling distribution of H is approximately χ^2 with $m-1$ degrees of freedom.

William Henry Kruskal (1919–2005) was born in New York City. He studied mathematics and statistics at Antioch College, Harvard, and Columbia, and joined the University of Chicago in 1951. He made many outstanding contributions to linear models, nonparametric statistics, government statistics, and the history and methodology of statistics.

Wilson Allen Wallis (1912–1998) was born in Philadelphia. He studied psychology and economics at the Universities of Minnesota and Chicago and at Columbia. He taught at Yale, Stanford, and Chicago, before moving as president (later chancellor) to the University of Rochester in 1962. He also served in several Republican administrations. Wallis served as editor of the *Journal of the American Statistical Association*, coauthored a popular introduction to statistics, and contributed to nonparametric statistics.

Title

ladder — Ladder of powers

Syntax

Ladder of powers

```
ladder varname [if] [in] [ , generate(newvar) noadjust ]
```

Ladder-of-powers histograms

```
gladder varname [if] [in] [ , histogram_options combine_options ]
```

Ladder-of-powers quantile–normal plots

```
qladder varname [if] [in] [ , qnorm_options combine_options ]
```

`by` is allowed with `ladder`; see [D] **by**.

Menu

ladder

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder of powers

gladder

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers histograms

qladder

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers quantile-normal plots

Description

`ladder` searches a subset of the ladder of powers (Tukey 1977) for a transform that converts *varname* into a normally distributed variable. `sktest` tests for normality; see [R] **sktest**. Also see [R] **boxcox**.

`gladder` displays nine histograms of transforms of *varname* according to the ladder of powers. `gladder` is useful pedagogically, but we do not advise looking at histograms for research work; `ladder` or `qnorm` (see [R] **diagnostic plots**) is preferred.

`qladder` displays the quantiles of transforms of *varname* according to the ladder of powers against the quantiles of a normal distribution.

Options for ladder

Main

`generate(`*newvar*`)` saves the transformed values corresponding to the minimum chi-squared value from the table. We do not recommend using `generate()` because it is literal in interpreting the minimum, thus ignoring nearly equal but perhaps more interpretable transforms.

`noadjust` is the `noadjust` option to `sktest`; see [R] **sktest**.

Options for gladder

histogram_options affect the rendition of the histograms across all relevant transformations; see [R] **histogram**. Here the `normal` option is assumed, so you must supply the `nonormal` option to suppress the overlaid normal density. Also, `gladder` does not allow the `width(#)` option of `histogram`.

combine_options are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Options for qladder

qnorm_options affect the rendition of the quantile–normal plots across all relevant transformations. See [R] **diagnostic plots**.

combine_options are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

▷ Example 1: ladder

We have data on the mileage rating of 74 automobiles and wish to find a transform that makes the variable normally distributed:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ladder mpg
```

Transformation	formula	chi2(2)	P(chi2)
cubic	mpg^3	43.59	0.000
square	mpg^2	27.03	0.000
identity	mpg	10.95	0.004
square root	sqrt(mpg)	4.94	0.084
log	log(mpg)	0.87	0.647
1/(square root)	1/sqrt(mpg)	0.20	0.905
inverse	1/mpg	2.36	0.307
1/square	1/(mpg^2)	11.99	0.002
1/cubic	1/(mpg^3)	24.30	0.000

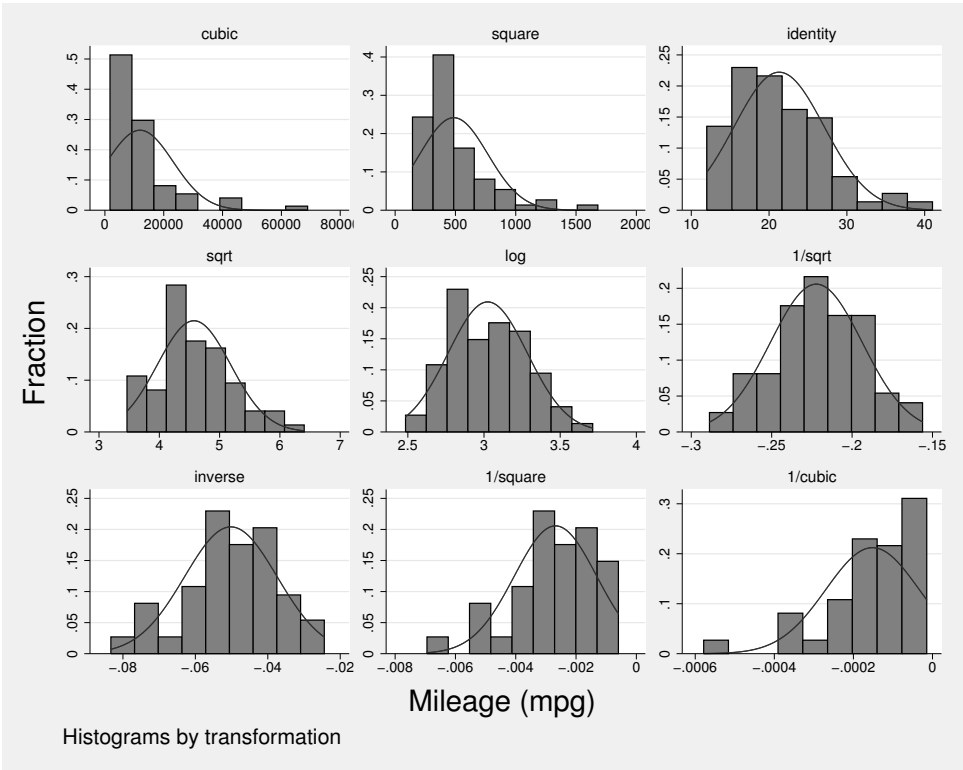
If we had typed `ladder mpg, gen(mpgx)`, the variable `mpgx` containing $1/\sqrt{\texttt{mpg}}$ would have been automatically generated for us. This is the perfect example of why you should not, in general, specify the `generate()` option. We also cannot reject the hypothesis that the inverse of `mpg` is normally distributed and that $1/\texttt{mpg}$—gallons per mile—has a better interpretation. It is a measure of energy consumption.

◁

▷ Example 2: gladder

`gladder` explores the same transforms as `ladder` but presents results graphically:

```
. gladder mpg, fraction
```



◁

❑ Technical note

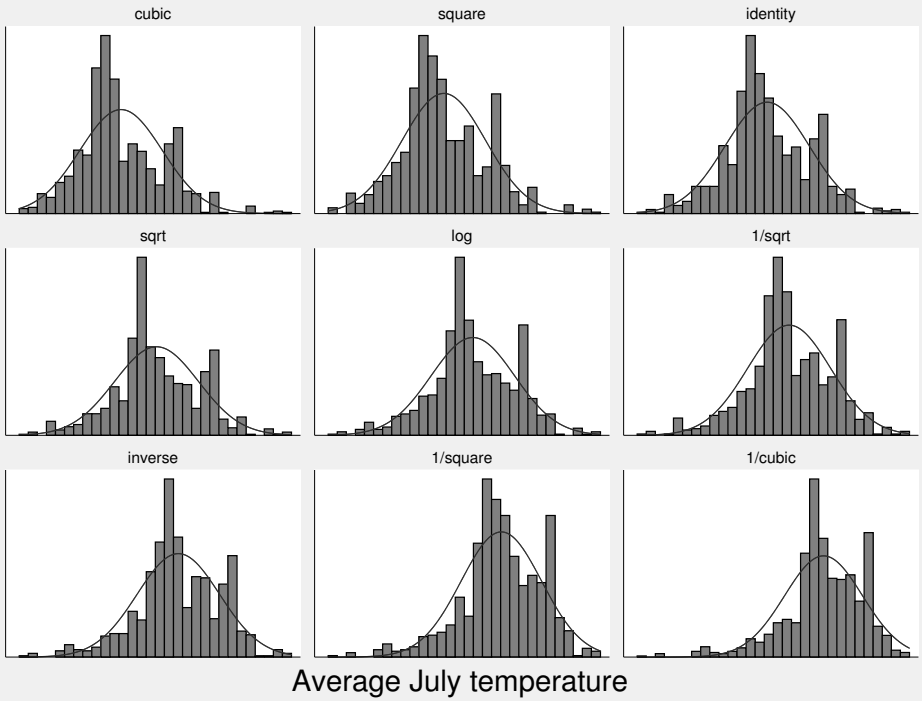
`gladder` is useful pedagogically, but be careful when using it for research work, especially with many observations. For instance, consider the following data on the average July temperature in degrees Fahrenheit for 954 U.S. cities:

```
. use http://www.stata-press.com/data/r12/citytemp
(City Temperature Data)
. ladder tempjuly
Transformation          formula                chi2(2)       P(chi2)
-----------------------------------------------------------------------
cubic                   tempjuly^3               47.49         0.000
square                  tempjuly^2               19.70         0.000
identity                tempjuly                  3.83         0.147
square root             sqrt(tempjuly)            1.83         0.400
log                     log(tempjuly)             5.40         0.067
1/(square root)         1/sqrt(tempjuly)         13.72         0.001
inverse                 1/tempjuly               26.36         0.000
1/square                1/(tempjuly^2)           64.43         0.000
1/cubic                 1/(tempjuly^3)               .         0.000
```

The period in the last line indicates that the χ^2 is very large; see [R] **sktest**.

From the table, we see that there is certainly a difference in normality between the square and square-root transform. If, however, you can see the difference between the transforms in the diagram below, you have better eyes than we do:

```
. gladder tempjuly, l1title("") ylabel(none) xlabel(none)
```

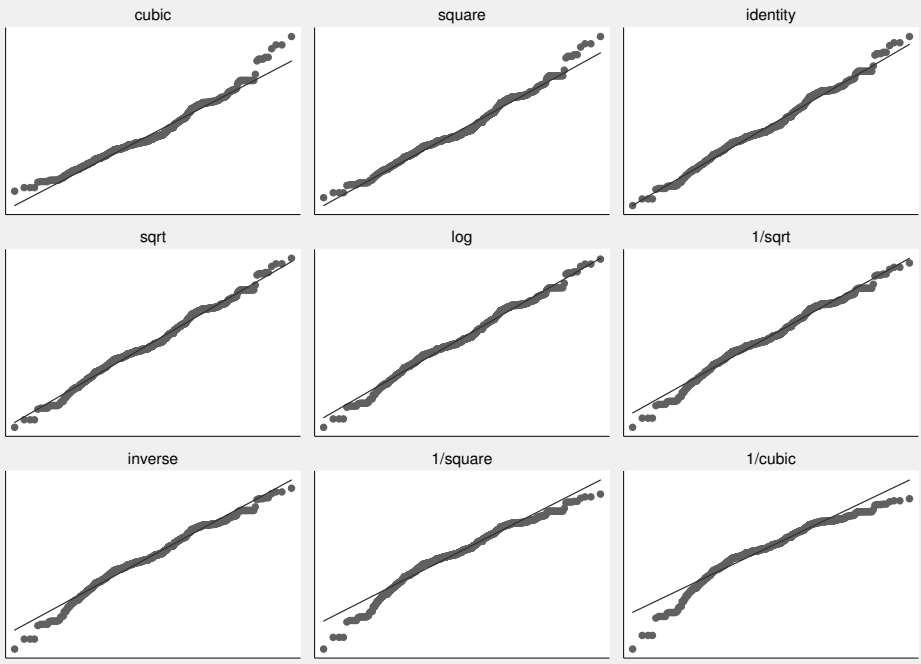


❑

▷ Example 3: qladder

A better graph for seeing normality is the quantile–normal graph, which can be produced by `qladder`.

```
. qladder tempjuly, ylabel(none) xlabel(none)
```



Quantile–Normal plots by transformation

This graph shows that for the square transform, the upper tail—and only the upper tail—diverges from what would be expected. This divergence is detected by `sktest` (see [R] **sktest**) as a problem with skewness, as we would learn from using `sktest` to examine `tempjuly` squared and square rooted.

◁

Saved results

`ladder` saves the following in `r()`:

Scalars

`r(N)`	number of observations
`r(invcube)`	χ^2 for inverse-cubic transformation
`r(P_invcube)`	significance level for inverse-cubic transformation
`r(invsq)`	χ^2 for inverse-square transformation
`r(P_invsq)`	significance level for inverse-square transformation
`r(inv)`	χ^2 for inverse transformation
`r(P_inv)`	significance level for inverse transformation
`r(invsqrt)`	χ^2 for inverse-root transformation
`r(P_invsqrt)`	significance level for inverse-root transformation
`r(log)`	χ^2 for log transformation
`r(P_log)`	significance level for log transformation
`r(sqrt)`	χ^2 for square-root transformation
`r(P_sqrt)`	significance level for square-root transformation
`r(ident)`	χ^2 for untransformed data
`r(P_ident)`	significance level for untransformed data
`r(square)`	χ^2 for square transformation
`r(P_square)`	significance level for square transformation
`r(cube)`	χ^2 for cubic transformation
`r(P_cube)`	significance level for cubic transformation

Methods and formulas

`ladder`, `gladder`, and `qladder` are implemented as ado-files.

For `ladder`, results are as reported by `sktest`; see [R] **sktest**. If `generate()` is specified, the transform with the minimum χ^2 value is chosen.

`gladder` sets the number of bins to $\min(\sqrt{n}, 10\log_{10} n)$, rounded to the closest integer, where n is the number of unique values of *varname*. See [R] **histogram** for a discussion of the optimal number of bins.

Also see Findley (1990) for a ladder-of-powers variable transformation program that produces one-way graphs with overlaid box plots, in addition to histograms with overlaid normals. Buchner and Findley (1990) discuss ladder-of-powers transformations as one aspect of preliminary data analysis. Also see Hamilton (1992, 18–23) and Hamilton (2009, 142–144).

Acknowledgment

`qladder` was written by Jeroen Weesie, Utrecht University, Utrecht, The Netherlands.

Title

level — Set default confidence level

Syntax

```
set level # [, permanently]
```

Description

`set level` specifies the default confidence level for confidence intervals for all commands that report confidence intervals. The initial value is 95, meaning 95% confidence intervals. # may be between 10.00 and 99.99, and # can have at most two digits after the decimal point.

Option

`permanently` specifies that, in addition to making the change right now, the `level` setting be remembered and become the default setting when you invoke Stata.

Remarks

To change the level of confidence intervals reported by a particular command, you need not reset the default confidence level. All commands that report confidence intervals have a `level(#)` option. When you do not specify the option, the confidence intervals are calculated for the default level set by `set level`, or for 95% if you have not reset `set level`.

▷ Example 1

We use the `ci` command to obtain the confidence interval for the mean of `mpg`:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ci mpg
    Variable |       Obs        Mean    Std. Err.       [95% Conf. Interval]
-------------+--------------------------------------------------------------
         mpg |        74      21.2973    .6725511         19.9569    22.63769
```

To obtain 90% confidence intervals, we would type

```
. ci mpg, level(90)
    Variable |       Obs        Mean    Std. Err.       [90% Conf. Interval]
-------------+--------------------------------------------------------------
         mpg |        74      21.2973    .6725511        20.17683    22.41776
```

or

```
. set level 90
. ci mpg
    Variable |       Obs        Mean    Std. Err.       [90% Conf. Interval]
-------------+--------------------------------------------------------------
         mpg |        74      21.2973    .6725511        20.17683    22.41776
```

If we opt for the second alternative, the next time that we fit a model (say, with `regress`), 90% confidence intervals will be reported. If we wanted 95% confidence intervals, we could specify `level(95)` on the estimation command, or we could reset the default by typing `set level 95`.

The current setting of `level()` is stored as the c-class value `c(level)`; see [P] **creturn**.

Title

lincom — Linear combinations of estimators

Syntax

`lincom` *exp* [, *options*]

options	Description
`eform`	generic label; `exp(b)`
`or`	odds ratio
`hr`	hazard ratio
`shr`	subhazard ratio
`irr`	incidence-rate ratio
`rrr`	relative-risk ratio
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats

where *exp* is any linear combination of coefficients that is a valid syntax for `test`; see [R] **test**. *exp* must not contain an equal sign.

Menu

Statistics > Postestimation > Linear combinations of estimates

Description

`lincom` computes point estimates, standard errors, t or z statistics, p-values, and confidence intervals for linear combinations of coefficients after any estimation command. Results can optionally be displayed as odds ratios, hazard ratios, incidence-rate ratios, or relative-risk ratios.

`lincom` can be used with `svy` estimation results; see [SVY] **svy postestimation**.

Options

`eform`, `or`, `hr`, `shr`, `irr`, and `rrr` all report coefficient estimates as $\exp(\widehat{\beta})$ rather than $\widehat{\beta}$. Standard errors and confidence intervals are similarly transformed. `or` is the default after `logistic`. The only difference in these options is how the output is labeled.

Option	Label	Explanation	Example commands
`eform`	`exp(b)`	Generic label	`cloglog`
`or`	`Odds Ratio`	Odds ratio	`logistic`, `logit`
`hr`	`Haz. Ratio`	Hazard ratio	`stcox`, `streg`
`shr`	`SHR`	Subhazard ratio	`stcrreg`
`irr`	`IRR`	Incidence-rate ratio	`poisson`
`rrr`	`RRR`	Relative-risk ratio	`mlogit`

exp may not contain any additive constants when you use the `eform`, `or`, `hr`, `irr`, or `rrr` option.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, and `sformat(%`*fmt*`)`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Using lincom
Odds ratios and incidence-rate ratios
Multiple-equation models

Using lincom

After fitting a model and obtaining estimates for coefficients $\beta_1, \beta_2, \ldots, \beta_k$, you may want to view estimates for linear combinations of the β_i, such as $\beta_1 - \beta_2$. `lincom` can display estimates for any linear combination of the form $c_0 + c_1\beta_1 + c_2\beta_2 + \cdots + c_k\beta_k$.

`lincom` works after any estimation command for which `test` works. Any valid expression for `test` syntax 1 (see [R] **test**) is a valid expression for `lincom`.

`lincom` is useful for viewing odds ratios, hazard ratios, etc., for one group (that is, one set of covariates) relative to another group (that is, another set of covariates). See the examples below.

▷ Example 1

We perform a linear regression:

```
. use http://www.stata-press.com/data/r12/regress
. regress y x1 x2 x3
```

Source	SS	df	MS	Number of obs =	148
				F(3, 144) =	96.12
Model	3259.3561	3	1086.45203	Prob > F =	0.0000
Residual	1627.56282	144	11.3025196	R-squared =	0.6670
				Adj R-squared =	0.6600
Total	4886.91892	147	33.2443464	Root MSE =	3.3619

To see the difference of the coefficients of `x2` and `x1`, we type

```
. lincom x2 - x1
 ( 1)  - x1 + x2 = 0
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
(1)	.7645682	.9950282	0.77	0.444	-1.20218	2.731316

The expression can be any linear combination.

```
. lincom 3*x1 + 500*x3
 ( 1)  3*x1 + 500*x3 = 0
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
(1)	1.301825	3.396624	0.38	0.702	-5.411858	8.015507

Nonlinear expressions are not allowed.

```
. lincom x2/x1
not possible with test
r(131);
```

For information about estimating nonlinear expressions, see [R] **nlcom**. ◁

❑ Technical note

`lincom` uses the same shorthands for coefficients as does `test` (see [R] **test**). When you type `x1`, for instance, `lincom` knows that you mean the coefficient of `x1`. The formal syntax for referencing this coefficient is actually `_b[x1]`, or alternatively, `_coef[x1]`. So, more formally, in the last example we could have typed

```
. lincom 3*_b[x1] + 500*_b[x3]
```
(*output omitted*)

❑

Odds ratios and incidence-rate ratios

After logistic regression, the `or` option can be specified with `lincom` to display odds ratios for any effect. Incidence-rate ratios after commands such as `poisson` can be similarly obtained by specifying the `irr` option.

▷ Example 2

Consider the low birthweight dataset from Hosmer and Lemeshow (2000, 25). We fit a logistic regression model of low birthweight (variable `low`) on the following variables:

Variable	Description	Coding
`age`	age in years	
`race`	race	1 if white, 2 if black, 3 if other
`smoke`	smoking status	1 if smoker, 0 if nonsmoker
`ht`	history of hypertension	1 if yes, 0 if no
`ui`	uterine irritability	1 if yes, 0 if no
`lwd`	maternal weight before pregnancy	1 if weight $<$ 110 lb., 0 otherwise
`ptd`	history of premature labor	1 if yes, 0 if no
`c.age##lwd`	`age` main effects, `lwd` main effects, and their interaction	
`smoke##lwd`	`smoke` main effects, `lwd` main effects, and their interaction	

We first fit a model without the interaction terms by using `logit`.

```
. use http://www.stata-press.com/data/r12/lbw3
(Hosmer & Lemeshow data)
. logit low age lwd i.race smoke ptd ht ui
Iteration 0:   log likelihood =   -117.336
Iteration 1:   log likelihood =   -99.3982
Iteration 2:   log likelihood = -98.780418
Iteration 3:   log likelihood = -98.777998
Iteration 4:   log likelihood = -98.777998
Logistic regression                               Number of obs   =        189
                                                  LR chi2(8)      =      37.12
                                                  Prob > chi2     =     0.0000
Log likelihood = -98.777998                       Pseudo R2       =     0.1582
```

low	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]

_cons	-1.216781	.9556797	-1.27	0.203	-3.089878	.656317

To get the odds ratio for black smokers relative to white nonsmokers (the reference group), we type

```
. lincom 2.race + smoke, or
 ( 1)  [low]2.race + [low]smoke = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	6.557805	4.744692	2.60	0.009	1.588176	27.07811

`lincom` computed $\exp(\beta_{\texttt{2.race}} + \beta_{\texttt{smoke}}) = 6.56$. To see the odds ratio for white smokers relative to black nonsmokers, we type

```
. lincom smoke - 2.race, or
 ( 1)  - [low]2.race + [low]smoke = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	.7662425	.4430176	-0.46	0.645	.2467334	2.379603

Now let's add the interaction terms to the model (Hosmer and Lemeshow 1989, table 4.10). This time, we will use `logistic` rather than `logit`. By default, `logistic` displays odds ratios.

```
. logistic low i.race ht ui ptd c.age##lwd smoke##lwd
Logistic regression                               Number of obs   =        189
                                                  LR chi2(10)     =      42.66
                                                  Prob > chi2     =     0.0000
Log likelihood =  -96.00616                       Pseudo R2       =     0.1818
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
race						
2	2.95383	1.532789	2.09	0.037	1.068277	8.167465

age	.9194513	.041896	-1.84	0.065	.8408967	1.005344
1.lwd	.1772934	.3312384	-0.93	0.354	.0045539	6.902367
lwd#c.age						
1	1.15883	.09602	1.78	0.075	.9851215	1.36317
1.smoke	3.168096	1.452378	2.52	0.012	1.289956	7.78076
smoke#lwd						
1 1	.2447849	.2003996	-1.72	0.086	.0491956	1.217988
_cons	.599443	.6519163	-0.47	0.638	.0711271	5.051971

Hosmer and Lemeshow (1989, table 4.13) consider the effects of smoking (`smoke` = 1) and low maternal weight before pregnancy (`lwd` = 1). The effect of smoking among non–low-weight mothers (`lwd` = 0) is given by the odds ratio 3.17 for `smoke` in the `logistic` output. The effect of smoking among low-weight mothers is given by

```
. lincom 1.smoke + 1.smoke#1.lwd
 ( 1)  [low]1.smoke + [low]1.smoke#1.lwd = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	.7755022	.574951	-0.34	0.732	.1813465	3.316323

We did not have to specify the `or` option. After `logistic`, `lincom` assumes `or` by default.

The effect of low weight (`lwd` = 1) is more complicated because we fit an `age` × `lwd` interaction. We must specify the age of mothers for the effect. The effect among 30-year-old nonsmokers is given by

```
. lincom 1.lwd + 30*1.lwd#c.age
 ( 1)  [low]1.lwd + 30*[low]1.lwd#c.age = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	14.7669	13.5669	2.93	0.003	2.439264	89.39633

`lincom` computed $\exp(\beta_{\texttt{1.lwd}} + 30\beta_{\texttt{age\#1.lwd}}) = 14.8$. It may seem odd that we entered it as `1.lwd + 30*1.lwd#c.age`, but remember that these terms are just `lincom`'s (and `test`'s) shorthands for `_b[1.lwd]` and `_b[1.lwd#c.age]`. We could have typed

```
. lincom _b[1.lwd] + 30*_b[1.lwd#c.age]
 ( 1)  [low]1.lwd + 30*[low]1.lwd#c.age = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	14.7669	13.5669	2.93	0.003	2.439264	89.39633

Multiple-equation models

`lincom` also works with multiple-equation models. The only difference is how you refer to the coefficients. Recall that for multiple-equation models, coefficients are referenced using the syntax

[*eqno*]*varname*

where *eqno* is the equation number or equation name and *varname* is the corresponding variable name for the coefficient; see [U] **13.5 Accessing coefficients and standard errors** and [R] **test** for details.

Example 3

Let's consider example 4 from [R] **mlogit** (Tarlov et al. 1989; Wells et al. 1989).

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite i.site, nolog
Multinomial logistic regression                 Number of obs   =        615
                                                LR chi2(10)     =      42.99
                                                Prob > chi2     =     0.0000
Log likelihood = -534.36165                     Pseudo R2       =     0.0387
```

_cons	-1.286943	.5923219	-2.17	0.030	-2.447872	-.1260134

To see the estimate of the sum of the coefficient of `male` and the coefficient of `nonwhite` for the `Prepaid` outcome, we type

```
. lincom [Prepaid]male + [Prepaid]nonwhite
 ( 1)  [Prepaid]male + [Prepaid]nonwhite = 0
```

insure	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	1.53647	.3272489	4.70	0.000	.8950741	2.177866

To view the estimate as a ratio of relative risks (see [R] **mlogit** for the definition and interpretation), we specify the `rrr` option.

```
. lincom [Prepaid]male + [Prepaid]nonwhite, rrr
 ( 1)  [Prepaid]male + [Prepaid]nonwhite = 0
```

insure	RRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	4.648154	1.521103	4.70	0.000	2.447517	8.827451

◁

Saved results

`lincom` saves the following in `r()`:

Scalars

`r(estimate)`	point estimate
`r(se)`	estimate of standard error
`r(df)`	degrees of freedom

Methods and formulas

`lincom` is implemented as an ado-file.

Title

linktest — Specification link test for single-equation models

Syntax

`linktest` [*if*] [*in*] [, *cmd_options*]

When `if` and `in` are not specified, the link test is performed on the same sample as the previous estimation.

Menu

Statistics > Postestimation > Tests > Specification link test for single-equation models

Description

`linktest` performs a link test for model specification after any single-equation estimation command, such as `logistic`, `regress`, `stcox`, etc.

Option

Main

cmd_options must be the same options specified with the underlying estimation command, except the *display_options* may differ.

Remarks

The form of the link test implemented here is based on an idea of Tukey (1949), which was further described by Pregibon (1980), elaborating on work in his unpublished thesis (Pregibon 1979). See *Methods and formulas* below for more details.

▷ Example 1

We want to explain the mileage ratings of cars in our automobile dataset by using the weight, engine displacement, and whether the car is manufactured outside the United States:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight displ foreign
```

Source	SS	df	MS
Model	1619.71935	3	539.906448
Residual	823.740114	70	11.7677159
Total	2443.45946	73	33.4720474

Number of obs	74
F(3, 70)	45.88
Prob > F	0.0000
R-squared	0.6629
Adj R-squared	0.6484
Root MSE	3.4304

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.0067745	.0011665	-5.81	0.000	-.0091011	-.0044479
displacement	.0019286	.0100701	0.19	0.849	-.0181556	.0220129
foreign	-1.600631	1.113648	-1.44	0.155	-3.821732	.6204699
_cons	41.84795	2.350704	17.80	0.000	37.15962	46.53628

On the basis of the R^2, we are reasonably pleased with this model.

If our model really is specified correctly, then if we were to regress `mpg` on the prediction and the prediction squared, the prediction squared would have no explanatory power. This is what `linktest` does:

```
. linktest
```

Source	SS	df	MS		
				Number of obs	= 74
				F(2, 71)	= 76.75
Model	1670.71514	2	835.357572	Prob > F	= 0.0000
Residual	772.744316	71	10.8837228	R-squared	= 0.6837
				Adj R-squared	= 0.6748
Total	2443.45946	73	33.4720474	Root MSE	= 3.299

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
_hat	-.4127198	.6577736	-0.63	0.532	-1.724283	.8988434
_hatsq	.0338198	.015624	2.16	0.034	.0026664	.0649732
_cons	14.00705	6.713276	2.09	0.041	.6211539	27.39294

We find that the prediction squared does have explanatory power, so our specification is not as good as we thought.

Although `linktest` is formally a test of the specification of the dependent variable, it is often interpreted as a test that, conditional on the specification, the independent variables are specified incorrectly. We will follow that interpretation and now include weight squared in our model:

```
. regress mpg weight c.weight#c.weight displ foreign
```

Source	SS	df	MS		
				Number of obs	= 74
				F(4, 69)	= 39.37
Model	1699.02634	4	424.756584	Prob > F	= 0.0000
Residual	744.433124	69	10.7888859	R-squared	= 0.6953
				Adj R-squared	= 0.6777
Total	2443.45946	73	33.4720474	Root MSE	= 3.2846

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.0173257	.0040488	-4.28	0.000	-.0254028	-.0092486
c.weight#c.weight	1.87e-06	6.89e-07	2.71	0.008	4.93e-07	3.24e-06
displacement	-.0101625	.0106236	-0.96	0.342	-.031356	.011031
foreign	-2.560016	1.123506	-2.28	0.026	-4.801349	-.3186832
_cons	58.23575	6.449882	9.03	0.000	45.36859	71.10291

Now we perform the link test on our new model:

```
. linktest
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =   81.08
       Model |  1699.39489     2  849.697445            Prob > F      =  0.0000
    Residual |   744.06457    71  10.4797827            R-squared     =  0.6955
-------------+------------------------------           Adj R-squared =  0.6869
       Total |  2443.45946    73  33.4720474            Root MSE      =  3.2372

-------------+----------------------------------------------------------------
        _hat |    1.141987   .7612218     1.50   0.138    -.3758456    2.659821
      _hatsq |   -.0031916   .0170194    -0.19   0.852    -.0371272    .0307441
       _cons |    -1.50305   8.196444    -0.18   0.855    -17.84629    14.84019
------------------------------------------------------------------------------
```

We now pass the link test.

◁

▷ Example 2

Above we followed a standard misinterpretation of the link test—when we discovered a problem, we focused on the explanatory variables of our model. We might consider varying exactly what the link test tests. The link test told us that our dependent variable was misspecified. For those with an engineering background, `mpg` is indeed a strange measure. It would make more sense to model energy consumption—gallons per mile—in terms of weight and displacement:

```
. gen gpm = 1/mpg
. regress gpm weight displ foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  3,    70) =   76.33
       Model |  .009157962     3  .003052654            Prob > F      =  0.0000
    Residual |  .002799666    70  .000039995            R-squared     =  0.7659
-------------+------------------------------           Adj R-squared =  0.7558
       Total |  .011957628    73  .000163803            Root MSE      =  .00632

------------------------------------------------------------------------------
         gpm |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |   .0000144   2.15e-06     6.72   0.000     .0000102    .0000187
displacement |   .0000186   .0000186     1.00   0.319    -.0000184    .0000557
     foreign |   .0066981   .0020531     3.26   0.002     .0026034    .0107928
       _cons |   .0008917   .0043337     0.21   0.838    -.0077515     .009535
------------------------------------------------------------------------------
```

This model looks every bit as reasonable as our original model:

```
. linktest
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =  117.06
       Model |  .009175219     2  .004587609            Prob > F      =  0.0000
    Residual |  .002782409    71  .000039189            R-squared     =  0.7673
-------------+------------------------------           Adj R-squared =  0.7608
       Total |  .011957628    73  .000163803            Root MSE      =  .00626

------------------------------------------------------------------------------
         gpm |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
        _hat |   .6608413    .515275     1.28   0.204    -.3665877     1.68827
      _hatsq |   3.275857   4.936655     0.66   0.509    -6.567553    13.11927
       _cons |    .008365   .0130468     0.64   0.523    -.0176496    .0343795
------------------------------------------------------------------------------
```

Specifying the model in terms of gallons per mile also solves the specification problem and results in a more parsimonious specification.

◁

▷ Example 3

The link test can be used with any single-equation estimation procedure, not solely regression. Let's turn our problem around and attempt to explain whether a car is manufactured outside the United States by its mileage rating and weight. To save paper, we will specify `logit`'s `nolog` option, which suppresses the iteration log:

```
. logit foreign mpg weight, nolog
Logistic regression                             Number of obs   =         74
                                                LR chi2(2)      =      35.72
                                                Prob > chi2     =     0.0000
Log likelihood = -27.175156                     Pseudo R2       =     0.3966

------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         mpg |  -.1685869   .0919175    -1.83   0.067    -.3487418     .011568
      weight |  -.0039067   .0010116    -3.86   0.000    -.0058894    -.001924
       _cons |   13.70837   4.518709     3.03   0.002     4.851859    22.56487
