------------------------------------------------------------------------------
```

When we run `linktest` after `logit`, the result is another logit specification:

```
. linktest, nolog
Logistic regression                             Number of obs   =         74
                                                LR chi2(2)      =      36.83
                                                Prob > chi2     =     0.0000
Log likelihood = -26.615714                     Pseudo R2       =     0.4090

------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
        _hat |   .8438531   .2738759     3.08   0.002     .3070661     1.38064
      _hatsq |  -.1559115   .1568642    -0.99   0.320    -.4633596     .1515366
       _cons |   .2630557   .4299598     0.61   0.541      -.57965     1.105761
------------------------------------------------------------------------------
```

The link test reveals no problems with our specification.

If there had been a problem, we would have been virtually forced to accept the misinterpretation of the link test—we would have reconsidered our specification of the independent variables. When using `logit`, we have no control over the specification of the dependent variable other than to change likelihood functions.

We admit to having seen a dataset once for which the link test rejected the logit specification. We did change the likelihood function, refitting the model using `probit`, and satisfied the link test. Probit has thinner tails than logit. In general, however, you will not be so lucky.

◁

❑ Technical note

You should specify the same options with `linktest` that you do with the estimation command, although you do not have to follow this advice as literally as we did in the preceding example. `logit`'s `nolog` option merely suppresses a part of the output, not what is estimated. We specified `nolog` both times to save paper.

If you are testing a tobit model, you must specify the censoring points just as you do with the `tobit` command.

If you are not sure which options are important, duplicate exactly what you specified on the estimation command.

If you do not specify `if` *exp* or `in` *range* with `linktest`, Stata will by default perform the link test on the same sample as the previous estimation. Suppose that you omitted some data when performing your estimation, but want to calculate the link test on all the data, which you might do if you believe the model is appropriate for all the data. You would type `linktest if e(sample) < .` to do this.

❑

Saved results

`linktest` saves the following in `r()`:

Scalars

`r(t)`	t statistic on `_hatsq`
`r(df)`	degrees of freedom

`linktest` is *not* an estimation command in the sense that it leaves previous estimation results unchanged. For instance, after running a regression and performing the link test, typing `regress` without arguments after the link test still replays the original regression.

For integrating an estimation command with `linktest`, `linktest` assumes that the name of the estimation command is stored in `e(cmd)` and that the name of the dependent variable is stored in `e(depvar)`. After estimation, it assumes that the number of degrees of freedom for the t test is given by `e(df_m)` if the macro is defined.

If the estimation command reports z statistics instead of t statistics, `linktest` will also report z statistics. The z statistic, however, is still returned in `r(t)`, and `r(df)` is set to a missing value.

Methods and formulas

`linktest` is implemented as an ado-file.

The link test is based on the idea that if a regression or regression-like equation is properly specified, you should be able to find no additional independent variables that are significant except by chance. One kind of specification error is called a link error. In regression, this means that the dependent variable needs a transformation or "link" function to properly relate to the independent variables. The idea of a link test is to add an independent variable to the equation that is especially likely to be significant if there is a link error.

Let

$$\mathbf{y} = f(\mathbf{X}\boldsymbol{\beta})$$

be the model and $\widehat{\boldsymbol{\beta}}$ be the parameter estimates. `linktest` calculates

$$\texttt{\_hat} = \mathbf{X}\widehat{\boldsymbol{\beta}}$$

and

$$\texttt{\_hatsq} = \texttt{\_hat}^2$$

The model is then refit with these two variables, and the test is based on the significance of `_hatsq`. This is the form suggested by Pregibon (1979) based on an idea of Tukey (1949). Pregibon (1980) suggests a slightly different method that has come to be known as "Pregibon's goodness-of-link test". We prefer the older version because it is universally applicable, straightforward, and a good second-order approximation. It can be applied to any single-equation estimation technique, whereas Pregibon's more recent tests are estimation-technique specific.

Title

lnskew0 — Find zero-skewness log or Box–Cox transform

Syntax

Zero-skewness log transform

`lnskew0` *newvar* `=` *exp* [*if*] [*in*] [`,` *options*]

Zero-skewness Box–Cox transform

`bcskew0` *newvar* `=` *exp* [*if*] [*in*] [`,` *options*]

options	Description
Main	
`delta(#)`	increment for derivative of skewness function; default is `delta(0.02)` for `lnskew0` and `delta(0.01)` for `bcskew0`
`zero(#)`	value for determining convergence; default is `zero(0.001)`
`level(#)`	set confidence level; default is `level(95)`

Menu

lnskew0

Data > Create or change data > Other variable-creation commands > Zero-skewness log transform

bcskew0

Data > Create or change data > Other variable-creation commands > Box-Cox transform

Description

`lnskew0` creates $newvar = \ln(\pm exp - k)$, choosing k and the sign of *exp* so that the skewness of *newvar* is zero.

`bcskew0` creates $newvar = (exp^{\lambda} - 1)/\lambda$, the Box–Cox power transformation (Box and Cox 1964), choosing λ so that the skewness of *newvar* is zero. *exp* must be strictly positive. Also see [R] **boxcox** for maximum likelihood estimation of λ.

Options

Main

`delta(#)` specifies the increment used for calculating the derivative of the skewness function with respect to k (`lnskew0`) or λ (`bcskew0`). The default values are 0.02 for `lnskew0` and 0.01 for `bcskew0`.

`zero(#)` specifies a value for skewness to determine convergence that is small enough to be considered zero and is, by default, 0.001.

`level(#)` specifies the confidence level for the confidence interval for k (`lnskew0`) or λ (`bcskew0`). The confidence interval is calculated only if `level()` is specified. # is specified as an integer; 95 means 95% confidence intervals. The `level()` option is honored only if the number of observations exceeds 7.

Remarks

▷ Example 1: lnskew0

Using our automobile dataset (see [U] **1.2.2 Example datasets**), we want to generate a new variable equal to $\ln(\texttt{mpg} - k)$ to be approximately normally distributed. `mpg` records the miles per gallon for each of our cars. One feature of the normal distribution is that it has skewness 0.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. lnskew0 lnmpg = mpg
      Transform |          k     [95% Conf. Interval]       Skewness
----------------+---------------------------------------------------
      ln(mpg-k) |   5.383659      (not calculated)        -7.05e-06
```

This created the new variable $\texttt{lnmpg} = \ln(\texttt{mpg} - 5.384)$:

```
. describe lnmpg
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
lnmpg           float  %9.0g                  ln(mpg-5.383659)
```

Because we did not specify the `level()` option, no confidence interval was calculated. At the outset, we could have typed

```
. use http://www.stata-press.com/data/r12/auto, clear
(Automobile Data)
. lnskew0 lnmpg = mpg, level(95)
      Transform |          k     [95% Conf. Interval]       Skewness
----------------+---------------------------------------------------
      ln(mpg-k) |   5.383659    -17.12339   9.892416       -7.05e-06
```

The confidence interval is calculated under the assumption that $\ln(\texttt{mpg} - k)$ really does have a normal distribution. It would be perfectly reasonable to use `lnskew0`, even if we did not believe that the transformed variable would have a normal distribution—if we literally wanted the zero-skewness transform—although, then the confidence interval would be an approximation of unknown quality to the true confidence interval. If we now wanted to test the believability of the confidence interval, we could also test our new variable `lnmpg` by using `swilk` (see [R] **swilk**) with the `lnnormal` option.

◁

❑ Technical note

`lnskew0` and `bcskew0` report the resulting skewness of the variable merely to reassure you of the accuracy of its results. In our example above, `lnskew0` found k such that the resulting skewness was -7×10^{-6}, a number close enough to zero for all practical purposes. If we wanted to make it even smaller, we could specify the `zero()` option. Typing `lnskew0 new=mpg, zero(1e-8)` changes the estimated k to 5.383552 from 5.383659 and reduces the calculated skewness to -2×10^{-11}.

When you request a confidence interval, `lnskew0` may report the lower confidence interval as '`.`', which should be taken as indicating the lower confidence limit $k_L = -\infty$. (This cannot happen with `bcskew0`.)

As an example, consider a sample of size n on x and assume that the skewness of x is positive, but not significantly so, at the desired significance level—say, 5%. Then no matter how large and negative you make k_L, there is no value extreme enough to make the skewness of $\ln(x - k_L)$ equal the corresponding percentile (97.5 for a 95% confidence interval) of the distribution of skewness in a normal distribution of the same sample size. You cannot do this because the distribution of $\ln(x - k_L)$ tends to that of x—apart from location and scale shift—as $x \to \infty$. This "problem" never applies to the upper confidence limit, k_U, because the skewness of $\ln(x - k_U)$ tends to $-\infty$ as k tends upward to the minimum value of x.

❑

▷ Example 2: bcskew0

In example 1, using `lnskew0` with a variable such as `mpg` is probably undesirable. `mpg` has a natural zero, and we are shifting that zero arbitrarily. On the other hand, use of `lnskew0` with a variable such as temperature measured in Fahrenheit or Celsius would be more appropriate, as the zero is indeed arbitrary.

For a variable like `mpg`, it makes more sense to use the Box–Cox power transform (Box and Cox 1964):

$$y^{(\lambda)} = \frac{y^{\lambda} - 1}{\lambda}$$

λ is free to take on any value, but $y^{(1)} = y - 1$, $y^{(0)} = \ln(y)$, and $y^{(-1)} = 1 - 1/y$.

`bcskew0` works like `lnskew0`:

```
. bcskew0 bcmpg = mpg, level(95)
      Transform |          L     [95% Conf. Interval]       Skewness
----------------+---------------------------------------------------
    (mpg^L-1)/L |  -.3673283    -1.212752    .4339645       .0001898
```

The 95% confidence interval includes $\lambda = -1$ (λ is labeled `L` in the output), which has a rather more pleasing interpretation—gallons per mile—than $(\texttt{mpg}^{-0.3673} - 1)/(-0.3673)$. The confidence interval, however, is calculated assuming that the power transformed variable is normally distributed. It makes perfect sense to use `bcskew0`, even when you do not believe that the transformed variable will be normally distributed, but then the confidence interval is an approximation of unknown quality. If you believe that the transformed data are normally distributed, you can alternatively use `boxcox` to estimate λ; see [R] **boxcox**.

◁

Saved results

lnskew0 and bcskew0 save the following in r():

Scalars

r(gamma)	k (lnskew0)
r(lambda)	λ (bcskew0)
r(lb)	lower bound of confidence interval
r(ub)	upper bound of confidence interval
r(skewness)	resulting skewness of transformed variable

Methods and formulas

lnskew0 and bcskew0 are implemented as ado-files.

Skewness is as calculated by summarize; see [R] **summarize**. Newton's method with numeric, uncentered derivatives is used to estimate k (lnskew0) and λ (bcskew0). For lnskew0, the initial value is chosen so that the minimum of $x - k$ is 1, and thus $\ln(x - k)$ is 0. bcskew0 starts with $\lambda = 1$.

Acknowledgment

lnskew0 and bcskew0 were written by Patrick Royston of the MRC Clinical Trials Unit, London.

cmdlog using filename [ , append replace ]
```

Close command log, temporarily suspend logging, or resume logging

```
cmdlog { close | on | off }
```

Set default format for logs

```
set logtype { text | smcl } [ , permanently ]
```

Specify screen width

```
set linesize #
```

In addition to using the `log` command, you may access the capabilities of `log` by selecting **File > Log** from the menu and choosing one of the options in the list.

Menu

File > Log

Description

`log` allows you to make a full record of your Stata session. A log is a file containing what you type and Stata's output. You may start multiple log files at the same time, and you may refer to them with a *logname*. If you do not specify a *logname*, Stata will use the name `<unnamed>`.

`cmdlog` allows you to make a record of what you type during your Stata session. A command log contains only what you type, so it is a subset of a full log.

You can make full logs, command logs, or both simultaneously. Neither is produced until you tell Stata to start logging.

Command logs are always text files, making them easy to convert into do-files. (In this respect, it would make more sense if the default extension of a command log file was `.do` because command logs are do-files. The default is `.txt`, not `.do`, however, to keep you from accidentally overwriting your important do-files.)

Full logs are recorded in one of two formats: Stata Markup and Control Language (SMCL) or plain text. The default is SMCL, but you can use `set logtype` to change that, or you can specify an option to state the format you wish. We recommend SMCL because it preserves fonts and colors. SMCL logs can be converted to text or to other formats by using the `translate` command; see [R] **translate**. You can also use `translate` to produce printable versions of SMCL logs. SMCL logs can be viewed and printed from the Viewer, as can any text file; see [R] **view**.

When using multiple log files, you may have up to five SMCL logs and five text logs open at the same time.

`log` or `cmdlog`, typed without arguments, reports the status of logging. `log query`, when passed an optional *logname*, reports the status of that log.

`log using` and `cmdlog using` open a log file. `log close` and `cmdlog close` close the file. Between times, `log off` and `cmdlog off`, and `log on` and `cmdlog on`, can temporarily suspend and resume logging.

If *filename* is specified without an extension, one of the suffixes `.smcl`, `.log`, or `.txt` is added. The extension `.smcl` or `.log` is added by `log`, depending on whether the file format is SMCL or text. The extension `.txt` is added by `cmdlog`. If *filename* contains embedded spaces, remember to enclose it in double quotes.

`set logtype` specifies the default format in which full logs are to be recorded. Initially, full logs are recorded in SMCL format.

`set linesize` specifies the maximum width, in characters, of Stata output. Most commands in Stata do not respect `linesize`, because it is not important for most commands. Most users never need to `set linesize`, because it will automatically be reset if you resize your Results window. This is also why there is no `permanently` option allowed with `set linesize`. `set linesize` is for use with commands such as `list` and `display` and is typically used by programmers who wish the output of those commands to be wider or narrower than the current width of the Results window.

Options for use with both log and cmdlog

`append` specifies that results be appended to an existing file. If the file does not already exist, a new file is created.

`replace` specifies that *filename*, if it already exists, be overwritten. When you do not specify either `replace` or `append`, the file is assumed to be new. If the specified file already exists, an error message is issued and logging is not started.

Options for use with log

`text` and `smcl` specify the format in which the log is to be recorded. The default is complicated to describe but is what you would expect:

If you specify the file as *filename*`.smcl`, the default is to write the log in SMCL format (regardless of the value of `set logtype`).

If you specify the file as *filename*`.log`, the default is to write the log in text format (regardless of the value of `set logtype`).

If you type *filename* without an extension and specify neither the `smcl` option nor the `text` option, the default is to write the file according to the value of `set logtype`. If you have not `set logtype`, then that default is SMCL. Also, the *filename* you specified will be fixed to read *filename*`.smcl` if a SMCL log is being created or *filename*`.log` if a text log is being created.

If you specify either the `text` or `smcl` option, then what you specify determines how the log is written. If *filename* was specified without an extension, the appropriate extension is added for you.

If you open multiple log files, you may choose a different format for each file.

`name(`*logname*`)` specifies an optional name you may use to refer to the log while it is open. You can start multiple log files, give each a different *logname*, and then close, temporarily suspend, or resume them each individually.

Option for use with set logtype

`permanently` specifies that, in addition to making the change right now, the `logtype` setting be remembered and become the default setting when you invoke Stata.

Remarks

For a detailed explanation of logs, see [U] **15 Saving and printing output—log files**.

When you open a full log, the default is to show the name of the file and a time and date stamp:

```
. log using myfile
-------------------------------------------------------------------------------
      name:  <unnamed>
       log:  C:\data\proj1\myfile.smcl
  log type:  smcl
 opened on:  12 Jan 2011, 12:28:23
.
```

The above information will appear in the log. If you do not want this information to appear, precede the command by `quietly`:

```
. quietly log using myfile
```

quietly will not suppress any error messages or anything else you need to know.

Similarly, when you close a full log, the default is to show the full information,

```
. log close
      name:  <unnamed>
       log:  C:\data\proj1\myfile.smcl
  log type:  smcl
 closed on:  12 Jan 2011, 12:32:41
-------------------------------------------------------------------------------
```

and that information will also appear in the log. If you want to suppress that, type quietly log close.

Saved results

log and cmdlog save the following in r():

Macros

r(name)	*logname*
r(filename)	name of file
r(status)	on or off
r(type)	smcl or text

log query _all saves the following in r():

Scalars

r(numlogs)	number of open log files

For each open log file, log query _all also saves

r(name#)	*logname*
r(filename#)	name of file
r(status#)	on or off
r(type#)	smcl or text

where # varies between 1 and the value of r(numlogs). Be aware that # will not necessarily represent the order in which the log files were first opened, nor will it necessarily remain constant for a given log file upon multiple calls to log query.

Title

logistic — Logistic regression, reporting odds ratios

Syntax

`logistic` *depvar indepvars* [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`noconstant`	suppress constant term
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`asis`	retain perfect predictor variables
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`coef`	report estimated coefficients
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Binary outcomes > Logistic regression (reporting odds ratios)

Description

`logistic` fits a logistic regression model of *depvar* on *indepvars*, where *depvar* is a 0/1 variable (or, more precisely, a 0/non-0 variable). Without arguments, `logistic` redisplays the last `logistic` estimates. `logistic` displays estimates as odds ratios; to view coefficients, type `logit` after running `logistic`. To obtain odds ratios for any covariate pattern relative to another, see [R] **lincom**.

Options

Model

`noconstant`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`coef` causes `logistic` to report the estimated coefficients rather than the odds ratios (exponentiated coefficients). `coef` may be specified when the model is fit or may be used later to redisplay results. `coef` affects only how results are displayed and not how they are estimated.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The following option is available with `logistic` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

logistic and logit
Robust estimate of variance

logistic and logit

`logistic` provides an alternative and preferred way to fit maximum-likelihood logit models, the other choice being `logit` ([R] **logit**).

First, let's dispose of some confusing terminology. We use the words logit and logistic to mean the same thing: maximum likelihood estimation. To some, one or the other of these words connotes transforming the dependent variable and using weighted least squares to fit the model, but that is not how we use either word here. Thus the `logit` and `logistic` commands produce the same results.

The `logistic` command is generally preferred to the `logit` command because `logistic` presents the estimates in terms of odds ratios rather than coefficients. To some people, this may seem disadvantageous, but you can type `logit` without arguments after `logistic` to see the underlying coefficients. You should be cautious when interpreting the odds ratio of the constant term. Usually, this odds ratio represents the baseline odds of the model when all predictor variables are set to zero. However, you must verify that a zero value for all predictor variables in the model actually makes sense before continuing with this interpretation.

Nevertheless, [R] **logit** is still worth reading because `logistic` shares the same features as `logit`, including omitting variables due to collinearity or one-way causation.

For an introduction to logistic regression, see Lemeshow and Hosmer (2005), Pagano and Gauvreau (2000, 470–487), or Pampel (2000); for a complete but nonmathematical treatment, see Kleinbaum and Klein (2010); and for a thorough discussion, see Hosmer and Lemeshow (2000). See Gould (2000) for a discussion of the interpretation of logistic regression. See Dupont (2009) or Hilbe (2009) for a discussion of logistic regression with examples using Stata. For a discussion using Stata with an emphasis on model specification, see Vittinghoff et al. (2005).

Stata has a variety of commands for performing estimation when the dependent variable is dichotomous or polytomous. See Long and Freese (2006) for a book devoted to fitting these models with Stata. Here is a list of some estimation commands that may be of interest. See [I] **estimation commands** for a complete list of all of Stata's estimation commands.

▷ Example 1

Consider the following dataset from a study of risk factors associated with low birthweight described in Hosmer and Lemeshow (2000, 25).

```
. use http://www.stata-press.com/data/r12/lbw
(Hosmer & Lemeshow data)
. describe
Contains data from http://www.stata-press.com/data/r12/lbw.dta
  obs:           189                          Hosmer & Lemeshow data
 vars:            11                          15 Jan 2011 05:01
 size:         2,646

-------------------------------------------------------------------------------
Sorted by:
```

We want to investigate the causes of low birthweight. Here `race` is a categorical variable indicating whether a person is white (`race` = 1), black (`race` = 2), or some other race (`race` = 3). We want indicator (dummy) variables for `race` included in the regression, so we will use factor variables.

```
. logistic low age lwt i.race smoke ptl ht ui

------------------------------------------------------------------------------
```

The odds ratios are for a one-unit change in the variable. If we wanted the odds ratio for `age` to be in terms of 4-year intervals, we would type

```
. gen age4 = age/4
. logistic low age4 lwt i.race smoke ptl ht ui
(output omitted)
```

After `logistic`, we can type `logit` to see the model in terms of coefficients and standard errors:

```
. logit
Logistic regression                               Number of obs   =        189
                                                  LR chi2(8)      =      33.22
                                                  Prob > chi2     =     0.0001
Log likelihood =   -100.724                       Pseudo R2       =     0.1416
```

low	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
age4	-.1084012	.1458017	-0.74	0.457	-.3941673	.1773649
lwt	-.0151508	.0069259	-2.19	0.029	-.0287253	-.0015763
race						
2	1.262647	.5264101	2.40	0.016	.2309024	2.294392
3	.8620792	.4391532	1.96	0.050	.0013548	1.722804
smoke	.9233448	.4008266	2.30	0.021	.137739	1.708951
ptl	.5418366	.346249	1.56	0.118	-.136799	1.220472
ht	1.832518	.6916292	2.65	0.008	.4769494	3.188086
ui	.7585135	.4593768	1.65	0.099	-.1418484	1.658875
_cons	.4612239	1.20459	0.38	0.702	-1.899729	2.822176

If we wanted to see the `logistic` output again, we would type `logistic` without arguments.

◁

▷ Example 2

We can specify the confidence interval for the odds ratios with the `level()` option, and we can do this either at estimation time or when replaying the model. For instance, to see our first model in example 1 with narrower, 90% confidence intervals, we might type

```
. logistic, level(90)
Logistic regression                               Number of obs   =        189
                                                  LR chi2(8)      =      33.22
                                                  Prob > chi2     =     0.0001
Log likelihood =   -100.724                       Pseudo R2       =     0.1416
```

low	Odds Ratio	Std. Err.	z	P>|z|	[90% Conf.	Interval]

Robust estimate of variance

If you specify `vce(robust)`, Stata reports the robust estimate of variance described in [U] **20.20 Obtaining robust variance estimates**. Here is the model previously fit with the robust estimate of variance:

```
. logistic low age lwt i.race smoke ptl ht ui, vce(robust)
Logistic regression                             Number of obs   =        189
                                                Wald chi2(8)    =      29.02
                                                Prob > chi2     =     0.0003
Log pseudolikelihood =   -100.724               Pseudo R2       =     0.1416
```

low	Odds Ratio	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.9732636	.0329376	-0.80	0.423	.9108015	1.040009
lwt	.9849634	.0070209	-2.13	0.034	.9712984	.9988206
race						
2	3.534767	1.793616	2.49	0.013	1.307504	9.556051
3	2.368079	1.026563	1.99	0.047	1.012512	5.538501
smoke	2.517698	.9736417	2.39	0.017	1.179852	5.372537
ptl	1.719161	.7072902	1.32	0.188	.7675715	3.850476
ht	6.249602	4.102026	2.79	0.005	1.726445	22.6231

_cons	1.586014	1.939482	0.38	0.706	.144345	17.42658

Also you can specify `vce(cluster` *clustvar*`)` and then, within cluster, relax the assumption of independence. To illustrate this, we have made some fictional additions to the low-birthweight data.

Say that these data are not a random sample of mothers but instead are a random sample of mothers from a random sample of hospitals. In fact, that may be true—we do not know the history of these data.

Hospitals specialize, and it would not be too incorrect to say that some hospitals specialize in more difficult cases. We are going to show two extremes. In one, all hospitals are alike, but we are going to estimate under the possibility that they might differ. In the other, hospitals are strikingly different. In both cases, we assume that patients are drawn from 20 hospitals.

In both examples, we will fit the same model, and we will type the same command to fit it. Below are the same data we have been using but with a new variable, `hospid`, that identifies from which of the 20 hospitals each patient was drawn (and which we have made up):

```
. use http://www.stata-press.com/data/r12/hospid1, clear
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression                               Number of obs   =        189
                                                  Wald chi2(8)    =      49.67
                                                  Prob > chi2     =     0.0000
Log pseudolikelihood =   -100.724                 Pseudo R2       =     0.1416
                                (Std. Err. adjusted for 20 clusters in hospid)
```

low	Odds Ratio	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.9732636	.0397476	-0.66	0.507	.898396	1.05437
lwt	.9849634	.0057101	-2.61	0.009	.9738352	.9962187
race						
2	3.534767	2.013285	2.22	0.027	1.157563	10.79386
3	2.368079	.8451325	2.42	0.016	1.176562	4.766257
smoke	2.517698	.8284259	2.81	0.005	1.321062	4.79826
ptl	1.719161	.6676221	1.40	0.163	.8030814	3.680219
ht	6.249602	4.066275	2.82	0.005	1.74591	22.37086
ui	2.1351	1.093144	1.48	0.138	.7827337	5.824014
_cons	1.586014	1.661913	0.44	0.660	.2034094	12.36639

The standard errors are similar to the standard errors we have previously obtained, whether we used the robust or conventional estimators. In this example, we invented the hospital IDs randomly.

Here are the results of the estimation with the same data but with a different set of hospital IDs:

```
. use http://www.stata-press.com/data/r12/hospid2
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression                               Number of obs   =        189
                                                  Wald chi2(8)    =       7.19
                                                  Prob > chi2     =     0.5167
Log pseudolikelihood =   -100.724                 Pseudo R2       =     0.1416
                                (Std. Err. adjusted for 20 clusters in hospid)
```

low	Odds Ratio	Robust Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.9732636	.0293064	-0.90	0.368	.9174862	1.032432

ht	6.249602	7.165454	1.60	0.110	.660558	59.12808
ui	2.1351	1.411977	1.15	0.251	.5841231	7.804266
_cons	1.586014	1.946253	0.38	0.707	.1431423	17.573

Note the strikingly larger standard errors. What happened? In these data, women most likely to have low-birthweight babies are sent to certain hospitals, and the decision on likeliness is based not just on age, smoking history, etc., but on other things that doctors can see but that are not recorded in our data. Thus merely because a woman is at one of the centers identifies her to be more likely to have a low-birthweight baby.

Saved results

logistic saves the following in e():

Scalars

e(N)	number of observations
e(N_cds)	number of completely determined successes
e(N_cdf)	number of completely determined failures
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(r2_p)	pseudo-R-squared
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance of model test
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	logistic
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(mns)	vector of means of the independent variables
e(rules)	information about perfect predictors
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

`logistic` is implemented as an ado-file.

Define $\mathbf{x}_j$ as the (row) vector of independent variables, augmented by 1, and $\mathbf{b}$ as the corresponding estimated parameter (column) vector. The logistic regression model is fit by `logit`; see [R] **logit** for details of estimation.

The odds ratio corresponding to the ith coefficient is $\psi_i = \exp(b_i)$. The standard error of the odds ratio is $s_i^{\psi} = \psi_i s_i$, where s_i is the standard error of b_i estimated by `logit`.

Define $I_j = \mathbf{x}_j\mathbf{b}$ as the predicted index of the jth observation. The predicted probability of a positive outcome is

$$p_j = \frac{\exp(I_j)}{1+\exp(I_j)}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`logistic` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

logistic postestimation — Postestimation tools for logistic

Description

The following postestimation commands are of special interest after `logistic`:

Command	Description
`estat classification`	report various summary statistics, including the classification table
`estat gof`	Pearson or Hosmer–Lemeshow goodness-of-fit test
`lroc`	compute area under ROC curve and graph the curve
`lsens`	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate after the `svy` prefix.

For information about these commands, see below.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Special-interest postestimation commands

`estat classification` reports various summary statistics, including the classification table.

`estat gof` reports the Pearson goodness-of-fit test or the Hosmer–Lemeshow goodness-of-fit test.

`lroc` graphs the ROC curve and calculates the area under the curve.

`lsens` graphs sensitivity and specificity versus probability cutoff and optionally creates new variables containing these data.

`estat classification`, `estat gof`, `lroc`, and `lsens` produce statistics and graphs either for the estimation sample or for any set of observations. However, they always use the estimation sample by default. When weights, `if`, or `in` is used with `logistic`, it is not necessary to repeat the qualifier with these commands when you want statistics computed for the estimation sample. Specify `if`, `in`, or the `all` option only when you want statistics computed for a set of observations other than the estimation sample. Specify weights (only `fweights` are allowed with these commands) only when you want to use a different set of weights.

By default, `estat classification`, `estat gof`, `lroc`, and `lsens` use the last model fit by `logistic`. You may also directly specify the model to the `lroc` and `lsens` commands by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable *depvar*.

`estat classification` and `estat gof` require that the current estimation results be from `logistic`, `logit`, or `probit`. `lroc` and `lsens` commands may also be used after `logit` or `probit`. `estat classification`, `lroc`, and `lsens` may also be used after `ivprobit`.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [, *statistic* `nooffset` `rules` `asif`]

statistic	Description
Main	
`pr`	probability of a positive outcome; the default
`xb`	linear prediction
`stdp`	standard error of the prediction
* `dbeta`	Pregibon (1981) $\Delta\widehat{\beta}$ influence statistic
* `deviance`	deviance residual
* `dx2`	Hosmer and Lemeshow (2000) $\Delta\,\chi^2$ influence statistic
* `ddeviance`	Hosmer and Lemeshow (2000) $\Delta\,D$ influence statistic
* `hat`	Pregibon (1981) leverage
* `number`	sequential number of the covariate pattern
* `residuals`	Pearson residuals; adjusted for number sharing covariate pattern
* `rstandard`	standardized Pearson residuals; adjusted for number sharing covariate pattern
`score`	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981) $\Delta\widehat{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer and Lemeshow (2000, 144–145) jargon, this statistic is M-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

`deviance` calculates the deviance residual.

`dx2` calculates the Hosmer and Lemeshow (2000, 174) $\Delta\chi^2$ influence statistic, reflecting the decrease in the Pearson χ^2 that is due to the deletion of the observation and all others that share the same covariate pattern.

`ddeviance` calculates the Hosmer and Lemeshow (2000, 174) ΔD influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

`hat` calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

`number` numbers the covariate patterns—observations with the same covariate pattern have the same `number`. Observations not used in estimation have `number` set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

`residuals` calculates the Pearson residual as given by Hosmer and Lemeshow (2000, 145) and adjusted for the number of observations that share the same covariate pattern.

`rstandard` calculates the standardized Pearson residual as given by Hosmer and Lemeshow (2000, 173) and adjusted for the number of observations that share the same covariate pattern.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

Options

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `logistic`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. See example 1 in [R] **logit postestimation**.

`asif` requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model. See example 1 in [R] **logit postestimation**.

Syntax for estat classification

```
estat classification [ if ] [ in ] [ weight ] [ , class_options ]
```

class_options	Description
Main	
all	display summary statistics for all observations in the data
cutoff(#)	positive outcome threshold; default is cutoff(0.5)

fweights are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Postestimation > Reports and statistics

Options for estat classification

Main

all requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by logistic.

cutoff(#) specifies the value for determining whether an observation has a predicted positive outcome. An observation is classified as positive if its predicted probability is $\geq$ #. The default is 0.5.

Syntax for estat gof

```
estat gof [ if ] [ in ] [ weight ] [ , gof_options ]
```

gof_options	Description
Main	
group(#)	perform Hosmer–Lemeshow goodness-of-fit test using # quantiles
all	execute test for all observations in the data
outsample	adjust degrees of freedom for samples outside estimation sample
table	display table of groups used for test

fweights are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Postestimation > Reports and statistics

Options for estat gof

Main

`group(#)` specifies the number of quantiles to be used to group the data for the Hosmer–Lemeshow goodness-of-fit test. `group(10)` is typically specified. If this option is not given, the Pearson goodness-of-fit test is computed using the covariate patterns in the data as groups.

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified with `logistic`.

`outsample` adjusts the degrees of freedom for the Pearson and Hosmer–Lemeshow goodness-of-fit tests for samples outside the estimation sample. See *Samples other than the estimation sample* later in this entry.

`table` displays a table of the groups used for the Hosmer–Lemeshow or Pearson goodness-of-fit test with predicted probabilities, observed and expected counts for both outcomes, and totals for each group.

Syntax for lroc

`lroc` [*depvar*] [*if*] [*in*] [*weight*] [`,` *lroc_options*]

lroc_options	Description
Main	
`all`	compute area under ROC curve and graph curve for all observations
`nograph`	suppress graph
Advanced	
`beta(`*matname*`)`	row vector containing coefficients for a logistic model
Plot	
cline_options	change the look of the line
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

`fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Binary outcomes > Postestimation > ROC curve after logistic/logit/probit/ivprobit

Options for lroc

Main

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified by `logistic`.

`nograph` suppresses graphical output.

Advanced

`beta(`*matname*`)` specifies a row vector containing coefficients for a logistic model. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable *depvar* must be specified immediately after the command name. See *Models other than the last fitted model* later in this entry.

Plot

cline_options, *marker_options*, and *marker_label_options* affect the rendition of the ROC curve—the plotted points connected by lines. These options affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] ***cline_options***, [G-3] ***marker_options***, and [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for lsens

`lsens` [*depvar*] [*if*] [*in*] [*weight*] [`,` *lsens_options*]

lsens_options	Description
Main	
`all`	graph all observations in the data
`genprob(`*varname*`)`	create variable containing probability cutoffs
`gensens(`*varname*`)`	create variable containing sensitivity
`genspec(`*varname*`)`	create variable containing specificity
`replace`	overwrite existing variables
`nograph`	suppress the graph
Advanced	
`beta(`*matname*`)`	row vector containing coefficients for the model
Plot	
connect_options	affect rendition of the plotted points connected by lines
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

`fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Binary outcomes > Postestimation > Sensitivity/specificity plot

Options for lsens

Main

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified with `logistic`.

`genprob(`*varname*`)`, `gensens(`*varname*`)`, and `genspec(`*varname*`)` specify the names of new variables created to contain, respectively, the probability cutoffs and the corresponding sensitivity and specificity.

`replace` requests that existing variables specified for `genprob()`, `gensens()`, or `genspec()` be overwritten.

`nograph` suppresses graphical output.

Advanced

`beta(`*matname*`)` specifies a row vector containing coefficients for a logistic model. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable *depvar* must be specified immediately after the command name. See *Models other than the last fitted model* later in this entry.

Plot

connect_options affect the rendition of the plotted points connected by lines; see *connect_options* in [G-2] **graph twoway scatter**.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Remarks are presented under the following headings:

predict after logistic
predict without options
predict with the xb and stdp options
predict with the residuals option
predict with the number option
predict with the deviance option
predict with the rstandard option
predict with the hat option
predict with the dx2 option
predict with the ddeviance option
predict with the dbeta option
estat classification
estat gof
lroc
lsens
Samples other than the estimation sample
Models other than the last fitted model

predict after logistic

`predict` is used after `logistic` to obtain predicted probabilities, residuals, and influence statistics for the estimation sample. The suggested diagnostic graphs below are from Hosmer and Lemeshow (2000), where they are more elaborately explained. Also see Collett (2003, 129–168) for a thorough discussion of model checking.

predict without options

Typing `predict` *newvar* after estimation calculates the predicted probability of a positive outcome.

In example 1 of [R] **logistic**, we ran the model `logistic low age lwt i.race smoke ptl ht ui`. We obtain the predicted probabilities of a positive outcome by typing

```
. use http://www.stata-press.com/data/r12/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
  (output omitted)
. predict p
(option pr assumed; Pr(low))
. summarize p low
```

Variable	Obs	Mean	Std. Dev.	Min	Max
p	189	.3121693	.1913915	.0272559	.8391283
low	189	.3121693	.4646093	0	1

predict with the xb and stdp options

`predict` with the `xb` option calculates the linear combination $x_j\mathbf{b}$, where x_j are the independent variables in the jth observation and $\mathbf{b}$ is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data. The influence statistics described below are adjusted for replicated covariate patterns in the data.

predict with the residuals option

`predict` can calculate more than predicted probabilities. The Pearson residual is defined as the square root of the contribution of the covariate pattern to the Pearson χ^2 goodness-of-fit statistic, signed according to whether the observed number of positive responses within the covariate pattern is less than or greater than expected. For instance,

```
. predict r, residuals
. summarize r, detail
```

Pearson residual

Percentiles	Smallest		
1% -1.750923	-2.283885		
5% -1.129907	-1.750923		
10% -.9581174	-1.636279	Obs	189
25% -.6545911	-1.636279	Sum of Wgt.	189
50% -.3806923		Mean	-.0242299
	Largest	Std. Dev.	.9970949
75% .8162894	2.23879		
90% 1.510355	2.317558	Variance	.9941981
95% 1.747948	3.002206	Skewness	.8618271
99% 3.002206	3.126763	Kurtosis	3.038448

We notice the prevalence of a few large positive residuals:

```
. sort r
. list id r low p age race in -5/l
```

	id	r	low	p	age	race
185.	33	2.224501	1	.1681123	19	white
186.	57	2.23879	1	.166329	15	white
187.	16	2.317558	1	.1569594	27	other
188.	77	3.002206	1	.0998678	26	white
189.	36	3.126763	1	.0927932	24	white

predict with the number option

Covariate patterns play an important role in logistic regression. Two observations are said to share the same covariate pattern if the independent variables for the two observations are identical. Although we might think of having individual observations, the statistical information in the sample can be summarized by the covariate patterns, the number of observations with that covariate pattern, and the number of positive outcomes within the pattern. Depending on the model, the number of covariate patterns can approach or be equal to the number of observations, or it can be considerably less.

Stata calculates all the residual and diagnostic statistics in terms of covariate patterns, not observations. That is, all observations with the same covariate pattern are given the same residual and diagnostic statistics. Hosmer and Lemeshow (2000, 145–145) argue that such "M-asymptotic" statistics are more useful than "N-asymptotic" statistics.

To understand the difference, think of an observed positive outcome with predicted probability of 0.8. Taking the observation in isolation, the residual must be positive—we expected 0.8 positive responses and observed 1. This may indeed be the correct residual, but not necessarily. Under the M-asymptotic definition, we ask how many successes we observed across all observations with this covariate pattern. If that number were, say, six, and there were a total of 10 observations with this covariate pattern, then the residual is negative for the covariate pattern—we expected eight positive outcomes but observed six. `predict` makes this kind of calculation and then attaches the same residual to all observations in the covariate pattern.

Occasionally, you might want to find all observations sharing a covariate pattern. `number` allows you to do this:

```
. predict pattern, number
. summarize pattern
```

Variable	Obs	Mean	Std. Dev.	Min	Max
pattern	189	89.2328	53.16573	1	182

We previously fit the model `logistic low age lwt i.race smoke ptl ht ui` over 189 observations. There are 182 covariate patterns in our data.

predict with the deviance option

The deviance residual is defined as the square root of the contribution to the likelihood-ratio test statistic of a saturated model versus the fitted model. It has slightly different properties from the Pearson residual (see Hosmer and Lemeshow [2000, 145–147]):

```
. predict d, deviance
. summarize d, detail
                    deviance residual
-------------------------------------------------------------
      Percentiles      Smallest
 1%    -1.843472      -1.911621
 5%     -1.33477      -1.843472
10%    -1.148316      -1.843472       Obs                 189
25%    -.8445325      -1.674869       Sum of Wgt.         189
50%    -.5202702                      Mean           -.1228811
                       Largest        Std. Dev.       1.049237
75%     .9129041       1.894089
90%     1.541558       1.924457       Variance        1.100898
95%     1.673338       2.146583       Skewness        .6598857
99%     2.146583       2.180542       Kurtosis        2.036938
```

predict with the rstandard option

Pearson residuals do not have a standard deviation equal to 1. `rstandard` generates Pearson residuals normalized to have an *expected* standard deviation equal to 1.

```
. predict rs, rstandard
. summarize r rs
    Variable |       Obs        Mean    Std. Dev.       Min        Max
-------------+--------------------------------------------------------
           r |       189   -.0242299    .9970949  -2.283885   3.126763
          rs |       189   -.0279135    1.026406    -2.4478   3.149081

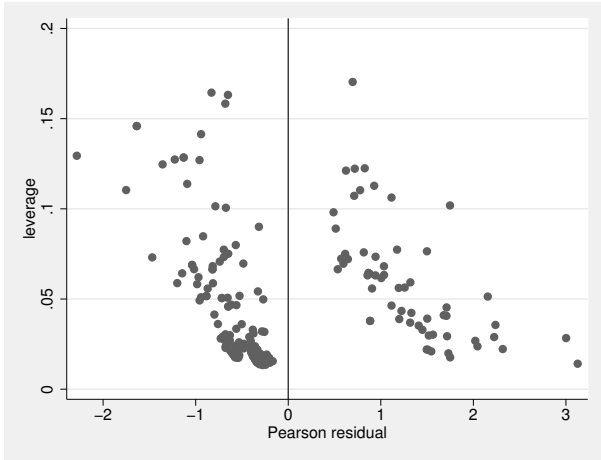
. correlate r rs
(obs=189)
             |        r       rs
-------------+------------------
           r |   1.0000
          rs |   0.9998   1.0000
```

Remember that we previously created `r` containing the (unstandardized) Pearson residuals. In these data, whether we use standardized or unstandardized residuals does not matter much.

predict with the hat option

`hat` calculates the leverage of a covariate pattern—a scaled measure of distance in terms of the independent variables. Large values indicate covariate patterns far from the average covariate pattern that can have a large effect on the fitted model even if the corresponding residual is small. Consider the following graph:

```
. predict h, hat
. scatter h r, xline(0)
```



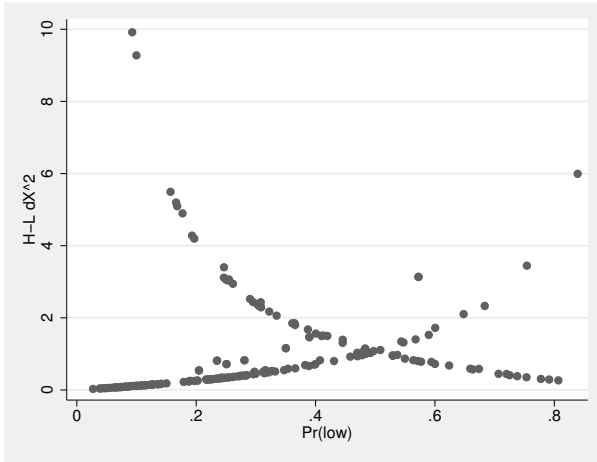
The points to the left of the vertical line are observed negative outcomes; here our data contain almost as many covariate patterns as observations, so most covariate patterns are unique. In such unique patterns, we observe either 0 or 1 success and expect p, thus forcing the sign of the residual. If we had fewer covariate patterns—if we did not have continuous variables in our model—there would be no such interpretation, and we would not have drawn the vertical line at 0.

Points on the left and right edges of the graph represent large residuals—covariate patterns that are not fit well by our model. Points at the top of our graph represent high leverage patterns. When analyzing the influence of observations on the model, we are most interested in patterns with high leverage and small residuals—patterns that might otherwise escape our attention.

predict with the dx2 option

There are many ways to measure influence, and `hat` is one example. `dx2` measures the decrease in the Pearson χ^2 goodness-of-fit statistic that would be caused by deleting an observation (and all others sharing the covariate pattern):

```
. predict dx2, dx2
. scatter dx2 p
```



Paraphrasing Hosmer and Lemeshow (2000, 178–179), the points going from the top left to the bottom right correspond to covariate patterns with the number of positive outcomes equal to the number in the group; the points on the other curve correspond to 0 positive outcomes. In our data, most of the covariate patterns are unique, so the points tend to lie along one or the other curves; the points that are off the curves correspond to the few repeated covariate patterns in our data in which all the outcomes are not the same.

We examine this graph for large values of `dx2`—there are two at the top left.

predict with the ddeviance option

Another measure of influence is the change in the deviance residuals due to deletion of a covariate pattern:

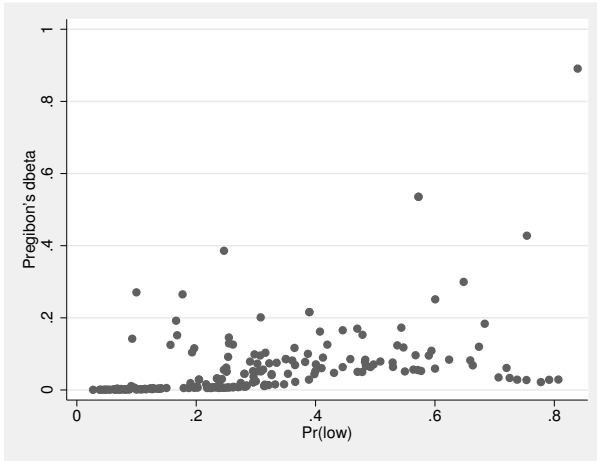
```
. predict dd, ddeviance
```

As with `dx2`, we typically graph `ddeviance` against the probability of a positive outcome. We direct you to Hosmer and Lemeshow (2000, 178) for an example and for the interpretation of this graph.

predict with the dbeta option

One of the more direct measures of influence of interest to model fitters is the Pregibon (1981) `dbeta` measure, a measure of the change in the coefficient vector that would be caused by deleting an observation (and all others sharing the covariate pattern):

```
. predict db, dbeta
. scatter db p
```



One observation has a large effect on the estimated coefficients. We can easily find this point:

```
. sort db
. list in 1
```

```
189.
+-------------------------------------------------------------------------------------------------------------+
|  id   low   age   lwt   race   smoke   ptl   ht   ui   ftv   bwt                                            |

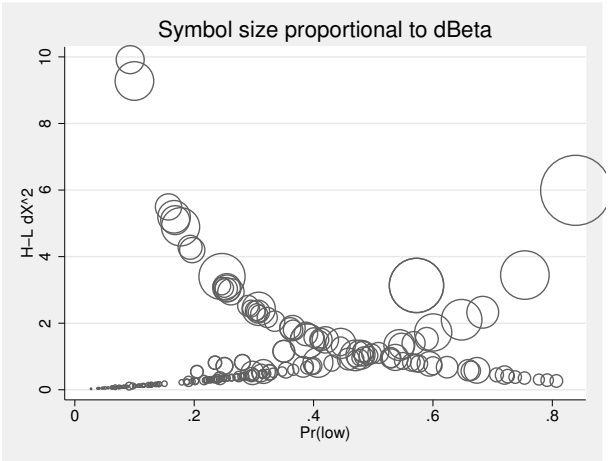
|-------------------------------------------------------------------------------------------------------------|
|       p          r   pattern          d          rs          h                                             |
| .8391283 -2.283885       117 -1.911621    -2.4478  .1294439                                                 |
|-------------------------------------------------------------------------------------------------------------|
|          dx2              dd              db                                                                |
|     5.991726        4.197658        .8909163                                                                |
+-------------------------------------------------------------------------------------------------------------+
```

Hosmer and Lemeshow (2000, 180) suggest a graph that combines two of the influence measures:

```
. scatter dx2 p [w=db], title("Symbol size proportional to dBeta") mfcolor(none)
(analytic weights assumed)
```



We can easily spot the most influential points by the `dbeta` and `dx2` measures.

estat classification

▷ Example 1

`estat classification` presents the classification statistics and classification table after `logistic`.

```
. use http://www.stata-press.com/data/r12/lbw, clear
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
  (output omitted)
. estat classification
Logistic model for low
                 -------- True --------
Classified |         D             ~D  |        Total
-----------+--------------------------+-----------------
     +     |        21             12  |           33
     -     |        38            118  |          156
-----------+--------------------------+-----------------
   Total   |        59            130  |          189
Classified + if predicted Pr(D) >= .5
True D defined as low != 0
--------------------------------------------------------
Sensitivity                     Pr( +| D)   35.59%
Specificity                     Pr( -|~D)   90.77%
Positive predictive value       Pr( D| +)   63.64%
Negative predictive value       Pr(~D| -)   75.64%
--------------------------------------------------------
False + rate for true ~D        Pr( +|~D)    9.23%
False - rate for true D         Pr( -| D)   64.41%
False + rate for classified +   Pr(~D| +)   36.36%
False - rate for classified -   Pr( D| -)   24.36%
--------------------------------------------------------
Correctly classified                        73.54%
--------------------------------------------------------
```

By default, estat classification uses a cutoff of 0.5, although you can vary this with the cutoff() option. You can use the lsens command to review the potential cutoffs; see *lsens* below.

◁

estat gof

estat gof computes goodness-of-fit tests: either the Pearson χ^2 test or the Hosmer–Lemeshow test.

By default, estat classification, estat gof, lroc, and lsens compute statistics for the estimation sample by using the last model fit by logistic. However, samples other than the estimation sample can be specified; see *Samples other than the estimation sample* later in this entry.

▷ Example 2

estat gof, typed without options, presents the Pearson χ^2 goodness-of-fit test for the fitted model. The Pearson χ^2 goodness-of-fit test is a test of the observed against expected number of responses using cells defined by the covariate patterns; see *predict with the number option* earlier in this entry for the definition of covariate patterns.

```
. estat gof
Logistic model for low, goodness-of-fit test
       number of observations =       189
 number of covariate patterns =       182
            Pearson chi2(173) =       179.24
                  Prob > chi2 =         0.3567
```

Our model fits reasonably well. However, the number of covariate patterns is close to the number of observations, making the applicability of the Pearson χ^2 test questionable but not necessarily inappropriate. Hosmer and Lemeshow (2000, 147–150) suggest regrouping the data by ordering on the predicted probabilities and then forming, say, 10 nearly equal-sized groups. estat gof with the group() option does this:

```
. estat gof, group(10)
Logistic model for low, goodness-of-fit test
  (Table collapsed on quantiles of estimated probabilities)
     number of observations =       189
           number of groups =        10
    Hosmer-Lemeshow chi2(8) =         9.65
                  Prob > chi2 =         0.2904
```

Again we cannot reject our model. If we specify the table option, estat gof displays the groups along with the expected and observed number of positive responses (low-birthweight babies):

```
. estat gof, group(10) table
```

Logistic model for low, goodness-of-fit test

(Table collapsed on quantiles of estimated probabilities)

Group	Prob	Obs_1	Exp_1	Obs_0	Exp_0	Total
1	0.0827	0	1.2	19	17.8	19
2	0.1276	2	2.0	17	17.0	19
3	0.2015	6	3.2	13	15.8	19
4	0.2432	1	4.3	18	14.7	19
5	0.2792	7	4.9	12	14.1	19

8	0.4828	7	8.2	12	10.8	19
9	0.5941	10	10.3	9	8.7	19
10	0.8391	13	12.8	5	5.2	18

```
      number of observations =       189
            number of groups =        10
    Hosmer-Lemeshow chi2(8) =      9.65
                Prob > chi2 =      0.2904
```

◁

❑ Technical note

`estat gof` with the `group()` option puts all observations with the same predicted probabilities into the same group. If, as in the previous example, we request 10 groups, the groups that `estat gof` makes are $[p_0, p_{10}]$, $(p_{10}, p_{20}]$, $(p_{20}, p_{30}]$, …, $(p_{90}, p_{100}]$, where p_k is the kth percentile of the predicted probabilities, with p_0 the minimum and p_{100} the maximum.

If there are many ties at the quantile boundaries, as will often happen if all independent variables are categorical and there are only a few of them, the sizes of the groups will be uneven. If the totals in some of the groups are small, the χ^2 statistic for the Hosmer–Lemeshow test may be unreliable. In this case, fewer groups should be specified, or the Pearson goodness-of-fit test may be a better choice.

❑

▷ Example 3

The `table` option can be used without the `group()` option. We would not want to specify this for our current model because there were 182 covariate patterns in the data, caused by including the two continuous variables, `age` and `lwt`, in the model. As an aside, we fit a simpler model and specify `table` with `estat gof`:

```
. logistic low i.race smoke ui
Logistic regression                               Number of obs   =        189
                                                  LR chi2(4)      =      18.80
                                                  Prob > chi2     =     0.0009
Log likelihood = -107.93404                       Pseudo R2       =     0.0801
```

```

◁

❑ Technical note

`logistic` and `estat gof` keep track of the estimation sample. If you type `logistic ... if x==1`, then when you type `estat gof`, the statistics will be calculated on the `x==1` subsample of the data automatically.

You should specify `if` or `in` with `estat gof` only when you wish to calculate statistics for a set of observations other than the estimation sample. See *Samples other than the estimation sample* later in this entry.

If the `logistic` model was fit with `fweights`, `estat gof` properly accounts for the weights in its calculations. (`estat gof` does not allow `pweights`.) You do not have to specify the weights when you run `estat gof`. Weights should be specified with `estat gof` only when you wish to use a different set of weights.

❑

lroc

Stata also has a suite of commands for performing both parametric and nonparametric receiver operating characteristic (ROC) analysis. See [R] **roc** for an overview of these commands.

`lroc` graphs the ROC curve—a graph of sensitivity versus one minus specificity as the cutoff c is varied—and calculates the area under it. Sensitivity is the fraction of observed positive-outcome cases that are correctly classified; specificity is the fraction of observed negative-outcome cases that are correctly classified. When the purpose of the analysis is classification, you must choose a cutoff.

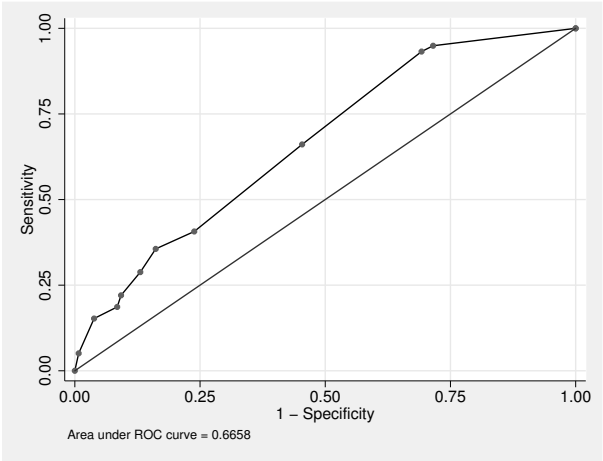
The curve starts at $(0, 0)$, corresponding to $c = 1$, and continues to $(1, 1)$, corresponding to $c = 0$. A model with no predictive power would be a 45° line. The greater the predictive power, the more bowed the curve, and hence the area beneath the curve is often used as a measure of the predictive power. A model with no predictive power has area 0.5; a perfect model has area 1.

The ROC curve was first discussed in signal detection theory (Peterson, Birdsall, and Fox 1954) and then was quickly introduced into psychology (Tanner and Swets 1954). It has since been applied in other fields, particularly medicine (for instance, Metz [1978]). For a classic text on ROC techniques, see Green and Swets (1966).

▷ Example 4

ROC curves are typically used when the point of the analysis is classification—which it is not in our low-birthweight model. Nevertheless, the ROC curve is

```
. lroc
Logistic model for low
number of observations =       189
area under ROC curve   =    0.6658
```

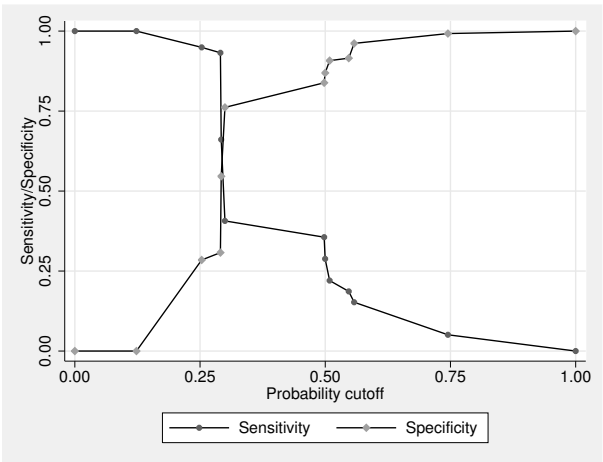


We see that the area under the curve is 0.6658.

lsens

`lsens` also plots sensitivity and specificity; it plots both sensitivity and specificity versus probability cutoff c. The graph is equivalent to what you would get from `estat classification` if you varied the cutoff probability from 0 to 1.

```
. lsens
```



`lsens` optionally creates new variables containing the probability cutoff, sensitivity, and specificity.

```
. lsens, genprob(p) gensens(sens) genspec(spec) nograph
```

The variables created will have $M + 2$ distinct nonmissing values: one for each of the M covariate patterns, one for $c = 0$, and another for $c = 1$. Values are recorded for $p = 0$, for each of the observed predicted probabilities, and for $p = 1$. The total number of observations required to do this can be fewer than _N, the same as _N, or _N + 1, or _N + 2. If more observations are added, they are added at the end of the dataset and the values of the original variables are set to missing in the added observations. How the values added align with existing observations is irrelevant.

Samples other than the estimation sample

`estat gof`, `estat classification`, `lroc`, and `lsens` can be used with samples other than the estimation sample. By default, these commands remember the estimation sample used with the last `logistic` command. To override this, simply use an `if` or `in` restriction to select another set of observations, or specify the `all` option to force the command to use all the observations in the dataset.

If you use `estat gof` with a sample that is completely different from the estimation sample (that is, no overlap), you should also specify the `outsample` option so that the χ^2 statistic properly adjusts the degrees of freedom upward. For an overlapping sample, the conservative thing to do is to leave the degrees of freedom the same as they are for the estimation sample.

▷ Example 5

We want to develop a model for predicting low-birthweight babies. One approach would be to divide our data into two groups, a developmental sample and a validation sample. See Lemeshow and Gall (1994) and Tilford, Roberson, and Fiser (1995) for more information on developing prediction models and severity-scoring systems.

We will do this with the low-birthweight data that we considered previously. First, we randomly divide the data into two samples.

```
. use http://www.stata-press.com/data/r12/lbw, clear
(Hosmer & Lemeshow data)
. set seed 1
. gen r = runiform()
. sort r
. gen group = 1 if _n <= _N/2
(95 missing values generated)
. replace group = 2 if group >=.
(95 real changes made)
```

Then we fit a model using the first sample (`group` = 1), which is our developmental sample.

```
. logistic low age lwt i.race smoke ptl ht ui if group==1
Logistic regression                             Number of obs   =         94
                                                LR chi2(8)      =      29.14
                                                Prob > chi2     =     0.0003
Log likelihood = -44.293342                     Pseudo R2       =     0.2475

------------------------------------------------------------------------------
         low | Odds Ratio   Std. Err.      z    P>|z|     [95% Conf. Interval]

         ptl |   3.033543   1.507048     2.23   0.025     1.145718     8.03198
          ht |   21.07656   22.64788     2.84   0.005     2.565304    173.1652
          ui |    .988479   .6699458    -0.02   0.986     .2618557    3.731409
       _cons |   30.73641   56.82168     1.85   0.064     .8204589    1151.462
------------------------------------------------------------------------------
```

To test calibration in the developmental sample, we calculate the Hosmer–Lemeshow goodness-of-fit test by using `estat gof`.

```
. estat gof, group(10)
Logistic model for low, goodness-of-fit test
  (Table collapsed on quantiles of estimated probabilities)
      number of observations =        94
            number of groups =        10
     Hosmer-Lemeshow chi2(8) =      6.67
                 Prob > chi2 =      0.5721
```

We did not specify an `if` statement with `estat gof` because we wanted to use the estimation sample. Because the test is not significant, we are satisfied with the fit of our model.

Running `lroc` gives a measure of the discrimination:

```
. lroc, nograph
Logistic model for low
number of observations =       94
area under ROC curve   =   0.8156
```

Now we test the calibration of our model by performing a goodness-of-fit test on the validation sample. We specify the `outsample` option so that the number of degrees of freedom is 10 rather than 8.

```
. estat gof if group==2, group(10) table outsample
Logistic model for low, goodness-of-fit test
  (Table collapsed on quantiles of estimated probabilities)
```

Group	Prob	Obs_1	Exp_1	Obs_0	Exp_0	Total
1	0.0725	1	0.4	9	9.6	10
2	0.1202	4	0.8	5	8.2	9
3	0.1549	3	1.3	7	8.7	10
4	0.1888	1	1.5	8	7.5	9
5	0.2609	3	2.2	7	7.8	10
6	0.3258	4	2.7	5	6.3	9
7	0.4217	2	3.7	8	6.3	10
8	0.4915	3	4.1	6	4.9	9
9	0.6265	4	5.5	6	4.5	10
10	0.9737	4	7.1	5	1.9	9

```
      number of observations =        95
            number of groups =        10
    Hosmer-Lemeshow chi2(10) =        28.03
                Prob > chi2 =         0.0018
```

We must acknowledge that our model does not fit well on the validation sample. The model's discrimination in the validation sample is appreciably lower, as well.

```
. lroc if group==2, nograph
Logistic model for low
number of observations =       95
area under ROC curve   =   0.5839
```

◁

Models other than the last fitted model

By default, `estat classification`, `estat gof`, `lroc`, and `lsens` use the last model fit by `logistic`. You may also directly specify the model to `lroc` and `lsens` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable *depvar* to these commands.

▷ Example 6

Suppose that someone publishes the following logistic model of low birthweight:

$$\Pr(\texttt{low}=1) = F(-0.02\,\texttt{age} - 0.01\,\texttt{lwt} + 1.3\,\texttt{black} + 1.1\,\texttt{smoke} + 0.5\,\texttt{ptl} + 1.8\,\texttt{ht} + 0.8\,\texttt{ui} + 0.5)$$

where F is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `_cons` for the constant (see [P] **matrix define** and [P] **matrix rownames**).

```
. use http://www.stata-press.com/data/r12/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons
```

Here we use `lroc` to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
number of observations =      189
area under ROC curve   =   0.7275
```

The area under the curve indicates that this model does have some predictive power. We could also obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

◁

Saved results

`estat classification` saves the following in `r()`:

Scalars

`r(P_corr)`	percent correctly classified
`r(P_p1)`	sensitivity
`r(P_n0)`	specificity
`r(P_p0)`	false-positive rate given true negative
`r(P_n1)`	false-negative rate given true positive
`r(P_1p)`	positive predictive value
`r(P_0n)`	negative predictive value
`r(P_0p)`	false-positive rate given classified positive
`r(P_1n)`	false-negative rate given classified negative

`estat gof` saves the following in `r()`:

Scalars

`r(N)`	number of observations
`r(m)`	number of covariate patterns or groups
`r(df)`	degrees of freedom
`r(chi2)`	χ^2

`lroc` saves the following in `r()`:

Scalars

`r(N)`	number of observations
`r(area)`	area under the ROC curve

`lsens` saves the following in `r()`:

Scalars

`r(N)`	number of observations

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Methods and formulas are presented under the following headings:

estat gof
predict after logistic
estat classification and lsens
lroc

estat gof

Let M be the total number of covariate patterns among the N observations. View the data as collapsed on covariate patterns $j = 1, 2, \ldots, M$, and define m_j as the total number of observations having covariate pattern j and y_j as the total number of positive responses among observations with covariate pattern j. Define p_j as the predicted probability of a positive outcome in covariate pattern j.

The Pearson χ^2 goodness-of-fit statistic is

$$\chi^2 = \sum_{j=1}^{M} \frac{(y_j - m_j p_j)^2}{m_j p_j (1 - p_j)}$$

This χ^2 statistic has approximately $M - k$ degrees of freedom for the estimation sample, where k is the number of independent variables, including the constant. For a sample outside the estimation sample, the statistic has M degrees of freedom.

The Hosmer–Lemeshow goodness-of-fit χ^2 (Hosmer and Lemeshow 1980; Lemeshow and Hosmer 1982; Hosmer, Lemeshow, and Klar 1988) is calculated similarly, except that rather than using the M covariate patterns as the group definition, the quantiles of the predicted probabilities are used to form groups. Let $G = \#$ be the number of quantiles requested with `group(#)`. The smallest index $1 \leq q(i) \leq M$, such that

$$W_{q(i)} = \sum_{j=1}^{q(i)} m_j \geq \frac{N}{G}$$

gives $p_{q(i)}$ as the upper boundary of the ith quantile for $i = 1, 2, \ldots, G$. Let $q(0) = 1$ denote the first index.

The groups are then

$$[p_{q(0)}, p_{q(1)}], (p_{q(1)}, p_{q(2)}], \ldots, (p_{q(G-1)}, p_{q(G)}]$$

If the `table` option is given, the upper boundaries $p_{q(1)}, \ldots, p_{q(G)}$ of the groups appear next to the group number on the output.

The resulting χ^2 statistic has approximately $G - 2$ degrees of freedom for the estimation sample. For a sample outside the estimation sample, the statistic has G degrees of freedom.

predict after logistic

Index j will now be used to index observations, not covariate patterns. Define M_j for each observation as the total number of observations sharing j's covariate pattern. Define Y_j as the total number of positive responses among observations sharing j's covariate pattern.

The Pearson residual for the jth observation is defined as

$$r_j = \frac{Y_j - M_j p_j}{\sqrt{M_j p_j (1 - p_j)}}$$

For $M_j > 1$, the deviance residual d_j is defined as

$$d_j = \pm \left(2 \left[Y_j \ln\left(\frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln\left\{ \frac{M_j - Y_j}{M_j (1 - p_j)} \right\} \right] \right)^{1/2}$$

where the sign is the same as the sign of $(Y_j - M_j p_j)$. In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} -\sqrt{2M_j|\ln(1-p_j)|} & \text{if } Y_j = 0 \\ \sqrt{2M_j|\ln p_j|} & \text{if } Y_j = M_j \end{cases}$$

The *unadjusted* diagonal elements of the hat matrix $h_{\mathrm{U}j}$ are given by $h_{\mathrm{U}j} = (\mathbf{X}\mathbf{V}\mathbf{X}')_{jj}$, where V is the estimated covariance matrix of parameters. The adjusted diagonal elements h_j created by `hat` are then $h_j = M_j p_j(1-p_j)h_{\mathrm{U}j}$.

The standardized Pearson residual $r_{\mathrm{S}j}$ is $r_j/\sqrt{1-h_j}$.

The Pregibon (1981) $\Delta\widehat{\beta}_j$ influence statistic is

$$\Delta\widehat{\beta}_j = \frac{r_j^2 h_j}{(1-h_j)^2}$$

The corresponding change in the Pearson χ^2 is $r_{\mathrm{S}j}^2$. The corresponding change in the deviance residual is $\Delta D_j = d_j^2/(1-h_j)$.

estat classification and lsens

Again let j index observations. Define c as the `cutoff()` specified by the user or, if not specified, as 0.5. Let p_j be the predicted probability of a positive outcome and y_j be the actual outcome, which we will treat as 0 or 1, although Stata treats it as 0 and non-0, excluding missing observations.

A prediction is classified as *positive* if $p_j \geq c$ and otherwise is classified as *negative*. The classification is *correct* if it is *positive* and $y_j = 1$ or if it is *negative* and $y_j = 0$.

Sensitivity is the fraction of $y_j = 1$ observations that are correctly classified. *Specificity* is the percentage of $y_j = 0$ observations that are correctly classified.

lroc

The ROC curve is a graph of *specificity* against $(1 - \textit{sensitivity})$. This is guaranteed to be a monotone nondecreasing function because the number of correctly predicted successes increases and the number of correctly predicted failures decreases as the classification cutoff c decreases.

The area under the ROC curve is the area on the bottom of this graph and is determined by integrating the curve. The vertices of the curve are determined by sorting the data according to the predicted index, and the integral is computed using the trapezoidal rule.

Title

logit — Logistic regression, reporting coefficients

Syntax

`logit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`noconstant`	suppress constant term
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`asis`	retain perfect predictor variables
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`or`	report odds ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`nocoef`	do not display coefficient table; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `nocoef`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`nocoef` and `coeflegend` do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Binary outcomes > Logistic regression

Description

`logit` fits a logit model for a binary response by maximum likelihood; it models the probability of a positive outcome given a set of regressors. *depvar* equal to nonzero and nonmissing (typically *depvar* equal to one) indicates a positive outcome, whereas *depvar* equal to zero indicates a negative outcome.

Also see [R] **logistic**; `logistic` displays estimates as odds ratios. Many users prefer the `logistic` command to `logit`. Results are the same regardless of which you use—both are the maximum-likelihood estimator. Several auxiliary commands that can be run after `logit`, `probit`, or `logistic` estimation are described in [R] **logistic postestimation**. A list of related estimation commands is given in [R] **logistic**.

If estimating on grouped data, see [R] **glogit**.

Options

Model

`noconstant`, `offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`or` reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The following options are available with `logit` but are not shown in the dialog box:

`nocoef` specifies that the coefficient table not be displayed. This option is sometimes used by program writers but is of no use interactively.

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Basic usage
Model identification

Basic usage

`logit` fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (or, more precisely, coded as 0 and not-0).

▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a logit model explaining whether a car is foreign on the basis of its weight and mileage. Here is an overview of our data:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. keep make mpg weight foreign
. describe
Contains data from http://www.stata-press.com/data/r12/auto.dta
  obs:            74                          1978 Automobile Data
 vars:             4                          13 Apr 2011 17:45
 size:         1,702                          (_dta has notes)
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------

mpg             int    %8.0g                  Mileage (mpg)
weight          int    %8.0gc                 Weight (lbs.)
foreign         byte   %8.0g       origin     Car type
-------------------------------------------------------------------------------
Sorted by:  foreign
     Note:  dataset has changed since last saved
. inspect foreign
foreign:  Car type                              Number of Observations
-----------------------                    ------------------------------
                                                Total   Integers   Nonintegers
|   #                          Negative           -          -          -
|   #                          Zero              52         52          -
|   #                          Positive          22         22          -
|   #                                           ----       ----       ----
|   #   #                      Total              74         74          -
|   #   #                      Missing            -
+-----------------------                        ----
0                       1                      74
   (2 unique values)
      foreign is labeled and all values are documented in the label.
```

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\texttt{foreign} = 1) = F(\beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{mpg})$$

where $F(z) = e^z/(1 + e^z)$ is the cumulative logistic distribution.

To fit this model, we type

```
. logit foreign weight mpg
Iteration 0:   log likelihood =  -45.03321
Iteration 1:   log likelihood = -29.238536
Iteration 2:   log likelihood = -27.244139
Iteration 3:   log likelihood = -27.175277
Iteration 4:   log likelihood = -27.175156
Iteration 5:   log likelihood = -27.175156
Logistic regression                               Number of obs   =         74
                                                  LR chi2(2)      =      35.72
                                                  Prob > chi2     =     0.0000
Log likelihood = -27.175156                       Pseudo R2       =     0.3966
------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]

         mpg |  -.1685869   .0919175    -1.83   0.067    -.3487418     .011568
       _cons |   13.70837   4.518709     3.03   0.002     4.851859    22.56487
------------------------------------------------------------------------------
```

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

◁

❑ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `logit` y x, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = \frac{\exp(\mathbf{x}_j\boldsymbol{\beta})}{1+\exp(\mathbf{x}_j\boldsymbol{\beta})}$$

❑

Model identification

The `logit` command has one more feature, and it is probably the most useful. `logit` automatically checks the model for identification and, if it is underidentified, drops whatever variables and observations are necessary for estimation to proceed. (`logistic`, `probit`, and `ivprobit` do this as well.)

▷ Example 2

Have you ever fit a logit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

Outcome y	Independent variable x
0	1
0	1
0	0
1	0

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero whenever the independent variable is one. In our data, $\Pr(y = 0 \mid x = 1) = 1$, which means that the logit coefficient on x must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have a lot of independent variables in your model. If you have ever had such difficulties, you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. In the meantime, you have been waiting. The estimates that you finally receive, if you receive any at all, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts us, fixes them, and properly fits the model.

Let's return to our automobile data. Among the variables we have in the data is one called `repair`, which takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
. use http://www.stata-press.com/data/r12/repair, clear
(1978 Automobile Data)
. tabulate foreign repair
```

	repair			
Car type	1	2	3	Total
Domestic	10	27	9	46
Foreign	0	3	9	12
Total	10	30	18	58

All the cars with poor repair records (`repair` = 1) are domestic. If we were to attempt to predict `foreign` on the basis of the repair records, the predicted probability for the `repair` = 1 category would have to be zero. This in turn means that the logit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try Stata on this problem.

```
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
      1.repair dropped and 10 obs not used
Iteration 0:   log likelihood = -26.992087
Iteration 1:   log likelihood = -22.483187
Iteration 2:   log likelihood = -22.230498
Iteration 3:   log likelihood = -22.229139
Iteration 4:   log likelihood = -22.229138
Logistic regression                               Number of obs   =         48
                                                  LR chi2(1)      =       9.53
                                                  Prob > chi2     =     0.0020

```

Remember that all the cars with poor repair records (`repair` = 1) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact "note: 1.repair !=0 predicts failure perfectly". This is Stata's mathematically precise way of saying what we said in English. When `repair` is 1, the car is domestic.

Stata then went on to say "1.repair dropped and 10 obs not used". This is Stata eliminating the problem. First `1.repair` had to be removed from the model because it would have an infinite coefficient. Then the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports "(empty)" in the row for `repair` = 1.

◁

❑ Technical note

Stata is pretty smart about catching problems like this. It will catch "one-way causation by a dummy variable", as we demonstrated above.

Stata also watches for "two-way causation", that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says, "so-and-so predicts outcome perfectly" and stops. Statistics dictates that no model can be fit.

Stata also checks your data for collinear variables; it will say, "so-and-so omitted because of collinearity". No observations need to be eliminated in this case, and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model `age`, and if all the persons over 65 died within the year, Stata would say, "age $>$ 65 predicts failure perfectly". It would then inform us about the fix-up it takes and fit what can be fit of our model.

logit (and logistic, probit, and ivprobit) will also occasionally display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

There are two causes for a message like this. The first—and most unlikely—case occurs when a continuous variable (or a combination of a continuous variable with other continuous or dummy variables) is simply a great predictor of the dependent variable. Consider Stata's auto.dta dataset with 6 observations removed.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. drop if foreign==0 & gear_ratio > 3.1
(6 observations deleted)
. logit foreign mpg weight gear_ratio, nolog
Logistic regression                             Number of obs   =         68
                                                LR chi2(3)      =      72.64
                                                Prob > chi2     =     0.0000
Log likelihood = -6.4874814                     Pseudo R2       =     0.8484

------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         mpg |  -.4944907   .2655508    -1.86   0.063    -1.014961    .0259792
      weight |  -.0060919    .003101    -1.96   0.049    -.0121698   -.000014
  gear_ratio |   15.70509   8.166234     1.92   0.054     -.300436    31.71061
       _cons |  -21.39527   25.41486    -0.84   0.400    -71.20747    28.41694
------------------------------------------------------------------------------
Note: 4 failures and 0 successes completely determined.
```

There are no missing standard errors in the output. If you receive the "completely determined" message and have one or more missing standard errors in your output, see the second case discussed below.

Note gear_ratio's large coefficient. logit thought that the 4 observations with the smallest predicted probabilities were essentially predicted perfectly.

```
. predict p
(option pr assumed; Pr(foreign))
. sort p
. list p in 1/4

     +-----------+
     |         p |
     |-----------|
  1. | 1.34e-10  |
  2. | 6.26e-09  |
  3. | 7.84e-09  |
  4. | 1.49e-08  |
     +-----------+
```

If this happens to you, you do not have to do anything. Computationally, the model is sound. The second case discussed below requires careful examination.

The second case occurs when the independent terms are all dummy variables or continuous ones with repeated values (for example, age). Here one or more of the estimated coefficients will have missing standard errors. For example, consider this dataset consisting of 5 observations.

```
. use http://www.stata-press.com/data/r12/logitxmpl, clear
. list, separator(0)

          x2 |     18.3704          .        .       .            .           .
       _cons |    -18.3704   1.414214   -12.99   0.000    -21.14221    -15.5986
------------------------------------------------------------------------------
Note: 2 failures and 0 successes completely determined.
convergence not achieved
r(430);
```

Three things are happening here. First, `logit` iterates almost forever and then declares nonconvergence. Second, `logit` can fit the outcome (`y` = 0) for the covariate pattern `x1` = 0 and `x2` = 0 (that is, the first two observations) perfectly. This observation is the "2 failures and 0 successes completely determined". Third, if this observation is dropped, then `x1`, `x2`, and the constant are collinear.

This is the cause of the nonconvergence, the message "completely determined", and the missing standard errors. It happens when you have a covariate pattern (or patterns) with only one outcome and there is collinearity when the observations corresponding to this covariate pattern are dropped.

If this happens to you, confirm the causes. First, identify the covariate pattern with only one outcome. (For your data, replace `x1` and `x2` with the independent variables of your model.)

```
. egen pattern = group(x1 x2)
. quietly logit y x1 x2, iterate(100)
. predict p
(option pr assumed; Pr(y))
```

```
. summarize p
```

Variable	Obs	Mean	Std. Dev.	Min	Max
p	6	.3333333	.2581989	1.05e-08	.5

If successes were completely determined, that means that there are predicted probabilities that are almost 1. If failures were completely determined, that means that there are predicted probabilities that are almost 0. The latter is the case here, so we locate the corresponding value of `pattern`:

```
. tabulate pattern if p < 1e-7
```

group(x1 x2)	Freq.	Percent	Cum.
1	2	100.00	100.00
Total	2	100.00	

Once we omit this covariate pattern from the estimation sample, `logit` can deal with the collinearity:

```
. logit y x1 x2 if pattern !=1, nolog
note: x2 omitted because of collinearity
Logistic regression                             Number of obs   =          4
                                                LR chi2(1)      =       0.00
                                                Prob > chi2     =     1.0000
Log likelihood = -2.7725887                     Pseudo R2       =     0.0000
```

y	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
x1	0	2	0.00	1.000	-3.919928	3.919928
x2	0	(omitted)				
_cons	0	1.414214	0.00	1.000	-2.771808	2.771808

We omit the collinear variable. Then we must decide whether to include or omit the observations with `pattern` $= 1$. We could include them,

```
. logit y x1, nolog
Logistic regression                             Number of obs   =          6
                                                LR chi2(1)      =       0.37
                                                Prob > chi2     =     0.5447
Log likelihood = -3.6356349                     Pseudo R2       =     0.0480
```

y	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
x1	1.098612	1.825742	0.60	0.547	-2.479776	4.677001
_cons	-1.098612	1.154701	-0.95	0.341	-3.361784	1.164559

or exclude them,

```
. logit y x1 if pattern != 1, nolog
Logistic regression                             Number of obs   =          4
                                                LR chi2(1)      =       0.00
                                                Prob > chi2     =     1.0000
Log likelihood = -2.7725887                     Pseudo R2       =     0.0000

------------------------------------------------------------------------------
           y |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
          x1 |          0           2     0.00   1.000    -3.919928    3.919928
       _cons |          0    1.414214     0.00   1.000    -2.771808    2.771808
------------------------------------------------------------------------------
```

If the covariate pattern that predicts outcome perfectly is meaningful, you may want to exclude these observations from the model. Here you would report that covariate pattern such and such predicted outcome perfectly and that the best model for the rest of the data is .... But, more likely, the perfect prediction was simply the result of having too many predictors in the model. Then you would omit the extraneous variables from further consideration and report the best model for all the data.

❑

Saved results

`logit` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(N_cds)`	number of completely determined successes
`e(N_cdf)`	number of completely determined failures
`e(k)`	number of parameters
`e(k_eq)`	number of equations in `e(b)`
`e(k_eq_model)`	number of equations in overall model test
`e(k_dv)`	number of dependent variables
`e(df_m)`	model degrees of freedom
`e(r2_p)`	pseudo-R-squared
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(chi2)`	χ^2
`e(p)`	significance of model test
`e(rank)`	rank of `e(V)`
`e(ic)`	number of iterations
`e(rc)`	return code
`e(converged)`	`1` if converged, `0` otherwise

Macros

e(cmd)	logit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(mns)	vector of means of the independent variables
e(rules)	information about perfect predictors
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

logit is implemented as an ado-file.

Cramer (2003, chap. 9) surveys the prehistory and history of the logit model. The word "logit" was coined by Berkson (1944) and is analogous to the word "probit". For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2010), Greene (2012), Jones (2007), Long (1997), Long and Freese (2006), Pampel (2000), or Powers and Xie (2008).

The likelihood function for logit is

$$\ln L = \sum_{j \in S} w_j \ln F(\mathbf{x}_j\mathbf{b}) + \sum_{j \notin S} w_j \ln\{1 - F(\mathbf{x}_j\mathbf{b})\}$$

where S is the set of all observations j, such that $y_j \neq 0$, $F(z) = e^z/(1+e^z)$, and w_j denotes the optional weights. $\ln L$ is maximized as described in [R] **maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. The scores are calculated as $\mathbf{u}_j = \{1 - F(\mathbf{x}_j\mathbf{b})\}\mathbf{x}_j$ for the positive outcomes and $-F(\mathbf{x}_j\mathbf{b})\mathbf{x}_j$ for the negative outcomes.

`logit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Joseph Berkson (1899–1982) was born in New York City and studied at the College of the City of New York, Columbia, and Johns Hopkins, earning both an MD and a doctorate in statistics. He then worked at Johns Hopkins before moving to the Mayo Clinic in 1931 as a biostatistician. Among many other contributions, his most influential one drew upon a long-sustained interest in the logistic function, especially his 1944 paper on bioassay, in which he introduced the term "logit". Berkson was a frequent participant in controversy—sometimes humorous, sometimes bitter—on subjects such as the evidence for links between smoking and various diseases and the relative merits of probit and logit methods and of different calculation methods.

Title

logit postestimation — Postestimation tools for logit

Description

The following postestimation commands are of special interest after `logit`:

Command	Description
`estat classification`	report various summary statistics, including the classification table
`estat gof`	Pearson or Hosmer–Lemeshow goodness-of-fit test
`lroc`	compute area under ROC curve and graph the curve
`lsens`	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate after the `svy` prefix.

For information about these commands, see [R] **logistic postestimation**.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

statistic	Description
Main	
pr	probability of a positive outcome; the default
xb	linear prediction
stdp	standard error of the prediction
* dbeta	Pregibon (1981) $\Delta\widehat{\beta}$ influence statistic
* deviance	deviance residual
* dx2	Hosmer and Lemeshow (2000) $\Delta\,\chi^2$ influence statistic
* ddeviance	Hosmer and Lemeshow (2000) $\Delta\,D$ influence statistic
* hat	Pregibon (1981) leverage
* number	sequential number of the covariate pattern
* residuals	Pearson residuals; adjusted for number sharing covariate pattern
* rstandard	standardized Pearson residuals; adjusted for number sharing covariate pattern
score	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981) $\Delta\widehat{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer and Lemeshow (2000, 144–145) jargon, this statistic is M-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

`deviance` calculates the deviance residual.

`dx2` calculates the Hosmer and Lemeshow (2000, 174) $\Delta\chi^2$ influence statistic, reflecting the decrease in the Pearson χ^2 that is due to deletion of the observation and all others that share the same covariate pattern.

`ddeviance` calculates the Hosmer and Lemeshow (2000, 174) ΔD influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

`hat` calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

`number` numbers the covariate patterns—observations with the same covariate pattern have the same `number`. Observations not used in estimation have `number` set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

`residuals` calculates the Pearson residual as given by Hosmer and Lemeshow (2000, 145) and adjusted for the number of observations that share the same covariate pattern.

`rstandard` calculates the standardized Pearson residual as given by Hosmer and Lemeshow (2000, 173) and adjusted for the number of observations that share the same covariate pattern.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

Options

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `logit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

`asif` requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model.

Remarks

Once you have fit a logit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] **20 Estimation and postestimation commands** and [R] **predict**. Here we will make only a few more comments.

`predict` without arguments calculates the predicted probability of a positive outcome, that is, $\Pr(y_j = 1) = F(\mathbf{x}_j\mathbf{b})$. With the `xb` option, `predict` calculates the linear combination $\mathbf{x}_j\mathbf{b}$, where $\mathbf{x}_j$ are the independent variables in the jth observation and $\mathbf{b}$ is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations, unless `rules` or `asif` is specified. For information about the other statistics available after `predict`, see [R] **logistic postestimation**.

▷ Example 1

In example 2 of [R] **logit**, we fit the logit model `logit foreign b3.repair`. To obtain predicted probabilities, type

```
. use http://www.stata-press.com/data/r12/repair
(1978 Automobile Data)
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
      1.repair dropped and 10 obs not used
  (output omitted)
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
```

```
. summarize foreign p
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
     foreign |         58    .2068966    .4086186          0          1
           p |         48         .25    .1956984         .1         .5
```

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. `logit` dropped the variable `1.repair` from our model and excluded 10 observations. Thus when we typed `predict p`, those same 10 observations were again excluded, and their predictions were set to missing.

`predict`'s `rules` option uses the rules in the prediction. During estimation, we were told "1.repair != 0 predicts failure perfectly", so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
(option pr assumed; Pr(foreign))
. summarize foreign p p2
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
     foreign |         58    .2068966    .4086186          0          1
           p |         48         .25    .1956984         .1         .5
          p2 |         58    .2068966    .2016268          0         .5
```

`predict`'s `asif` option ignores the rules and exclusion criteria and calculates predictions for all observations possible by using the estimated parameters from the model:

```
. predict p3, asif
(option pr assumed; Pr(foreign))
. summarize foreign p p2 p3
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
     foreign |         58    .2068966    .4086186          0          1
           p |         48         .25    .1956984         .1         .5
          p2 |         58    .2068966    .2016268          0         .5
          p3 |         58    .2931035    .2016268         .1         .5
```

Which is right? What `predict` does by default is the most conservative approach. If many observations had been excluded because of a simple rule, we could be reasonably certain that the `rules` prediction is correct. The `asif` prediction is correct only if the exclusion is a fluke, and we would be willing to exclude the variable from the analysis anyway. Then, however, we would refit the model to include the excluded observations.

◁

▷ Example 2

We can use the command `margins, contrast` after `logit` to make comparisons on the probability scale. Let's fit a model predicting low birthweight from characteristics of the mother:

```
. use http://www.stata-press.com/data/r12/lbw, clear
(Hosmer & Lemeshow data)
```

```
. logit low age i.race i.smoke ptl i.ht i.ui
Iteration 0:   log likelihood =   -117.336
Iteration 1:   log likelihood = -103.81846
Iteration 2:   log likelihood = -103.40486
Iteration 3:   log likelihood = -103.40384
Iteration 4:   log likelihood = -103.40384
Logistic regression                             Number of obs   =        189
                                                LR chi2(7)      =      27.86
                                                Prob > chi2     =     0.0002
Log likelihood = -103.40384                     Pseudo R2       =     0.1187
```

low	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	-.0403293	.0357127	-1.13	0.259	-.1103249	.0296663
race						
2	1.009436	.5025122	2.01	0.045	.0245302	1.994342
3	1.001908	.4248342	2.36	0.018	.1692485	1.834568
1.smoke	.9631876	.3904357	2.47	0.014	.1979477	1.728427
ptl	.6288678	.3399067	1.85	0.064	-.0373371	1.295073
1.ht	1.358142	.6289555	2.16	0.031	.125412	2.590872
1.ui	.8001832	.4572306	1.75	0.080	-.0959724	1.696339
_cons	-1.184127	.9187461	-1.29	0.197	-2.984837	.6165818

The coefficients are log odds-ratios: conditional on the other predictors, smoking during pregnancy is associated with an increase of 0.96 in the log odds-ratios of low birthweight. The model is linear in the log odds-scale, so the estimate of 0.96 has the same interpretation, whatever the values of the other predictors might be. We could convert 0.96 to an odds ratio by replaying the results with `logit, or`.

But what if we want to talk about the probability of low birthweight, and not the odds? Then we will need the command `margins, contrast`. We will use the `r.` contrast operator to compare each level of `smoke` with a reference level. (`smoke` has only two levels, so there will be only one comparison: a comparison of smokers with nonsmokers.)

```
. margins r.smoke, contrast
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(low), predict()
```

	df	chi2	P>chi2
smoke	1	6.32	0.0119

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
smoke (1 vs 0)	.1832779	.0728814	.0404329	.3261229

We see that maternal smoking is associated with an 18.3% increase in the probability of low birthweight. (We received a contrast in the probability scale because predicted probabilities are the default when `margins` is used after `logit`.)

The contrast of 18.3% is a difference of margins that are computed by averaging over the predictions for observations in the estimation sample. If the values of the other predictors were different, the contrast for `smoke` would be different, too. Let's estimate the contrast for 25-year-old mothers:

```
. margins r.smoke, contrast at(age=25)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(low), predict()
at           : age             =          25
```

	df	chi2	P>chi2
smoke	1	6.19	0.0129

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
smoke (1 vs 0)	.1808089	.0726777	.0383632	.3232547

Specifying a maternal `age` of 25 changed the contrast to 18.1%. Our contrast of probabilities changed because the `logit` model is nonlinear in the probability scale. A contrast of log odds-ratios would not have changed.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

See *Methods and formulas* of [R] **logistic postestimation** for details.

Title

loneway — Large one-way ANOVA, random effects, and reliability

Syntax

`loneway` *response_var group_var* [*if*] [*in*] [*weight*] [, *options*]

options	Description
Main	
`mean`	expected value of F distribution; default is 1
`median`	median of F distribution; default is 1
`exact`	exact confidence intervals (groups must be equal with no weights)
`level(#)`	set confidence level; default is `level(95)`

`by` is allowed; see [D] **by**.
`aweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Linear models and related > ANOVA/MANOVA > Large one-way ANOVA

Description

`loneway` fits one-way analysis-of-variance (ANOVA) models on datasets with many levels of *group_var* and presents different ancillary statistics from `oneway` (see [R] **oneway**):

Feature	`oneway`	`loneway`
Fit one-way model	x	x
on fewer than 376 levels	x	x
on more than 376 levels		x
Bartlett's test for equal variance	x	
Multiple-comparison tests	x	
Intragroup correlation and SE		x
Intragroup correlation confidence interval		x
Est. reliability of group-averaged score		x
Est. SD of group effect		x
Est. SD within group		x

Options

Main

`mean` specifies that the expected value of the $F_{k-1,N-k}$ distribution be used as the reference point F_m in the estimation of ρ instead of the default value of 1.

`median` specifies that the median of the $F_{k-1,N-k}$ distribution be used as the reference point F_m in the estimation of ρ instead of the default value of 1.

`exact` requests that exact confidence intervals be computed, as opposed to the default asymptotic confidence intervals. This option is allowed only if the groups are equal in size and weights are not used.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

Remarks

Remarks are presented under the following headings:

The one-way ANOVA model
R-squared
The random-effects ANOVA model
Intraclass correlation
Estimated reliability of the group-averaged score

The one-way ANOVA model

▷ Example 1

`loneway`'s output looks like that of `oneway`, except that `loneway` presents more information at the end. Using our automobile dataset, we have created a (numeric) variable called `manufacturer_grp` identifying the manufacturer of each car, and within each manufacturer we have retained a maximum of four models, selecting those with the lowest mpg. We can compute the intraclass correlation of mpg for all manufacturers with at least four models as follows:

```
. use http://www.stata-press.com/data/r12/auto7
(1978 Automobile Data)
. loneway mpg manufacturer_grp if nummake == 4
              One-way Analysis of Variance for mpg: Mileage (mpg)

                                              Number of obs =        36
                                                  R-squared =    0.5228

    Source                SS         df       MS            F     Prob > F
------------------------------------------------------------------------
Between manufactur~p   621.88889       8    77.736111      3.70     0.0049
Within manufactur~p       567.75      27    21.027778
------------------------------------------------------------------------
Total                  1189.6389      35    33.989683

         Intraclass       Asy.
         correlation      S.E.       [95% Conf. Interval]
         ------------------------------------------------
            0.40270     0.18770        0.03481     0.77060

         Estimated SD of manufactur~p effect     3.765247
         Estimated SD within manufactur~p        4.585605
         Est. reliability of a manufactur~p mean   .72950
              (evaluated at n=4.00)
```

◁

In addition to the standard one-way ANOVA output, `loneway` produces the R-squared, the estimated standard deviation of the group effect, the estimated standard deviation within group, the intragroup correlation, the estimated reliability of the group-averaged mean, and, for unweighted data, the asymptotic standard error and confidence interval for the intragroup correlation.

R-squared

The R-squared is, of course, simply the underlying R^2 for a regression of *response_var* on the levels of *group_var*, or `mpg` on the various manufacturers here.

The random-effects ANOVA model

`loneway` assumes that we observe a variable, y_{ij}, measured for n_i elements within k groups or classes such that

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}, \quad i = 1, 2, \ldots, k, \quad j = 1, 2, \ldots, n_i$$

and α_i and ϵ_{ij} are independent zero-mean random variables with variance σ_α^2 and σ_ϵ^2, respectively. This is the random-effects ANOVA model, also known as the components-of-variance model, in which it is typically assumed that the y_{ij} are normally distributed.

The interpretation with respect to our example is that the observed value of our response variable, `mpg`, is created in two steps. First, the ith manufacturer is chosen, and a value, α_i, is determined—the typical `mpg` for that manufacturer less the overall `mpg` μ. Then a deviation, ϵ_{ij}, is chosen for the jth model within this manufacturer. This is how much that particular automobile differs from the typical `mpg` value for models from this manufacturer.

For our sample of 36 car models, the estimated standard deviations are $\sigma_\alpha = 3.8$ and $\sigma_\epsilon = 4.6$. Thus a little more than half of the variation in `mpg` between cars is attributable to the car model, with the rest attributable to differences between manufacturers. These standard deviations differ from those that would be produced by a (standard) fixed-effects regression in that the regression would require the sum within each manufacturer of the ϵ_{ij}, $\epsilon_{i.}$ for the ith manufacturer, to be zero, whereas these estimates merely impose the constraint that the sum is *expected* to be zero.

Intraclass correlation

There are various estimators of the intraclass correlation, such as the pairwise estimator, which is defined as the Pearson product-moment correlation computed over all possible pairs of observations that can be constructed within groups. For a discussion of various estimators, see Donner (1986). `loneway` computes what is termed the analysis of variance, or ANOVA, estimator. This intraclass correlation is the theoretical upper bound on the variation in *response_var* that is explainable by *group_var*, of which R-squared is an overestimate because of the serendipity of fitting. This correlation is comparable to an R-squared—you do not have to square it.

In our example, the intra-`manu` correlation, the correlation of `mpg` within manufacturer, is 0.40. Because `aweights` were not used and the default correlation was computed (that is, the `mean` and `median` options were not specified), `loneway` also provided the asymptotic confidence interval and standard error of the intraclass correlation estimate.

Estimated reliability of the group-averaged score

The estimated reliability of the group-averaged score or mean has an interpretation similar to that of the intragroup correlation; it is a comparable number if we average *response_var* by *group_var*, or `mpg` by `manu` in our example. It is the theoretical upper bound of a regression of manufacturer-averaged `mpg` on characteristics of manufacturers. Why would we want to collapse our 36-observation dataset into a 9-observation dataset of manufacturer averages? Because the 36 observations might be a mirage. When General Motors builds cars, do they sometimes put a Pontiac label and sometimes a Chevrolet label on them, so that it appears in our data as if we have two cars when we really have

only one, replicated? If that were the case, and if it were the case for many other manufacturers, then we would be forced to admit that we do not have data on 36 cars; we instead have data on nine manufacturer-averaged characteristics.

Saved results

`loneway` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(rho_t)`	estimated reliability
`r(rho)`	intraclass correlation	`r(se)`	asymp. SE of intraclass correlation
`r(lb)`	lower bound of 95% CI for rho	`r(sd_w)`	estimated SD within group
`r(ub)`	upper bound of 95% CI for rho	`r(sd_b)`	estimated SD of group effect

Methods and formulas

`loneway` is implemented as an ado-file.

The mean squares in the `loneway`'s ANOVA table are computed as

$$\text{MS}_\alpha = \sum_i w_{i\cdot}(\overline{y}_{i\cdot} - \overline{y}_{\cdot\cdot})^2/(k-1)$$

and

$$\text{MS}_\epsilon = \sum_i \sum_j w_{ij}(y_{ij} - \overline{y}_{i\cdot})^2/(N-k)$$

in which

$$w_{i\cdot} = \sum_j w_{ij} \quad w_{\cdot\cdot} = \sum_i w_{i\cdot} \quad \overline{y}_{i\cdot} = \sum_j w_{ij}y_{ij}/w_{i\cdot} \quad \text{and} \quad \overline{y}_{\cdot\cdot} = \sum_i w_{i\cdot}\overline{y}_{i\cdot}/w_{\cdot\cdot}$$

The corresponding expected values of these mean squares are

$$E(\text{MS}_\alpha) = \sigma^2_\epsilon + g\sigma^2_\alpha \qquad \text{and} \qquad E(\text{MS}_\epsilon) = \sigma^2_\epsilon$$

in which

$$g = \frac{w_{\cdot\cdot} - \sum_i w^2_{i\cdot}/w_{\cdot\cdot}}{k-1}$$

In the unweighted case, we get

$$g = \frac{N - \sum_i n^2_i/N}{k-1}$$

As expected, $g = m$ for the case of no weights and equal group sizes in the data, that is, $n_i = m$ for all i. Replacing the expected values with the observed values and solving yields the ANOVA estimates of σ^2_α and σ^2_ϵ. Substituting these into the definition of the intraclass correlation

$$\rho = \frac{\sigma^2_\alpha}{\sigma^2_\alpha + \sigma^2_\epsilon}$$

yields the ANOVA estimator of the intraclass correlation:

$$\rho_A = \frac{F_{\text{obs}} - 1}{F_{\text{obs}} - 1 + g}$$

F_{obs} is the observed value of the F statistic from the ANOVA table. For no weights and equal n_i, ρ_A = roh, which is the intragroup correlation defined by Kish (1965). Two slightly different estimators are available through the `mean` and `median` options (Gleason 1997). If either of these options is specified, the estimate of ρ becomes

$$\rho = \frac{F_{\text{obs}} - F_m}{F_{\text{obs}} + (g-1)F_m}$$

For the `mean` option, $F_m = E(F_{k-1,N-K}) = (N-k)/(N-k-2)$, that is, the expected value of the ANOVA table's F statistic. For the `median` option, F_m is simply the median of the F statistic. Setting F_m to 1 gives ρ_A, so for large samples, these different point estimators are essentially the same. Also, because the intraclass correlation of the random-effects model is by definition nonnegative, for any of the three possible point estimators, ρ is truncated to zero if F_{obs} is less than F_m.

For no weighting, interval estimators for ρ_A are computed. If the groups are equal sized (all n_i equal) and the `exact` option is specified, the following exact (assuming that the y_{ij} are normally distributed) $100(1-\alpha)\%$ confidence interval is computed:

$$\left\{ \frac{F_{\text{obs}} - F_m F_u}{F_{\text{obs}} + (g-1)F_m F_u}, \frac{F_{\text{obs}} - F_m F_l}{F_{\text{obs}} + (g-1)F_m F_l} \right\}$$

with $F_m = 1$, $F_l = F_{\alpha/2,k-1,N-k}$, and $F_u = F_{1-\alpha/2,k-1,N-k}$, $F_{\cdot,k-1,N-k}$ being the cumulative distribution function for the F distribution with $k-1$ and $N-k$ degrees of freedom. If `mean` or `median` is specified, F_m is defined as above. If the groups are equal sized and `exact` is not specified, the following asymptotic $100(1-\alpha)\%$ confidence interval for ρ_A is computed,

$$\left[\rho_A - z_{\alpha/2}\sqrt{V(\rho_A)}, \rho_A + z_{\alpha/2}\sqrt{V(\rho_A)} \right]$$

where $z_{\alpha/2}$ is the $100(1-\alpha/2)$ percentile of the standard normal distribution and $\sqrt{V(\rho_A)}$ is the asymptotic standard error of ρ defined below. This confidence interval is also available for unequal groups. It is not applicable and, therefore, not computed for the estimates of ρ provided by the `mean` and `median` options. Again, because the intraclass coefficient is nonnegative, if the lower bound is negative for either confidence interval, it is truncated to zero. As might be expected, the coverage probability of a truncated interval is higher than its nominal value.

The asymptotic standard error of ρ_A, assuming that the y_{ij} are normally distributed, is also computed when appropriate, namely, for unweighted data and when ρ_A is computed (neither the `mean` option nor the `median` option is specified):

$$V(\rho_A) = \frac{2(1-\rho)^2}{g^2}(A + B + C)$$

with

$$A = \frac{\{1+\rho(g-1)\}^2}{N-k}$$

$$B = \frac{(1-\rho)\{1+\rho(2g-1)\}}{k-1}$$

$$C = \frac{\rho^2\{\sum n_i^2 - 2N^{-1}\sum n_i^3 + N^{-2}(\sum n_i^2)^2\}}{(k-1)^2}$$

and ρ_A is substituted for ρ (Donner 1986).

The estimated reliability of the group-averaged score, known as the Spearman–Brown prediction formula in the psychometric literature (Winer, Brown, and Michels 1991, 1014), is

$$\rho_t = \frac{t\rho}{1 + (t-1)\rho}$$

for group size t. `loneway` computes ρ_t for $t = g$.

The estimated standard deviation of the group effect is $\sigma_\alpha = \sqrt{(\text{MS}_\alpha - \text{MS}_\epsilon)/g}$. This deviation comes from the assumption that an observation is derived by adding a group effect to a within-group effect.

The estimated standard deviation within group is the square root of the mean square due to error, or $\sqrt{\text{MS}_\epsilon}$.

Acknowledgment

We thank John Gleason of Syracuse University (retired) for his contributions to improving `loneway`.

yvar and *xvar* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

Menu

Statistics > Nonparametric analysis > Lowess smoothing

Description

`lowess` carries out a locally weighted regression of *yvar* on *xvar*, displays the graph, and optionally saves the smoothed variable.

Warning: `lowess` is computationally intensive and may therefore take a long time to run on a slow computer. Lowess calculations on 1,000 observations, for instance, require performing 1,000 regressions.

Options

Main

`mean` specifies running-mean smoothing; the default is running-line least-squares smoothing.

`noweight` prevents the use of Cleveland's (1979) tricube weighting function; the default is to use the weighting function.

`bwidth(#)` specifies the bandwidth. Centered subsets of `bwidth()` $\times N$ observations are used for calculating smoothed values for each point in the data except for the end points, where smaller, uncentered subsets are used. The greater the `bwidth()`, the greater the smoothing. The default is 0.8.

`logit` transforms the smoothed *yvar* into logits. Predicted values less than 0.0001 or greater than 0.9999 are set to $1/N$ and $1 - 1/N$, respectively, before taking logits.

`adjust` adjusts the mean of the smoothed *yvar* to equal the mean of *yvar* by multiplying by an appropriate factor. This option is useful when smoothing binary (0/1) data.

`nograph` suppresses displaying the graph.

`generate(`*newvar*`)` creates *newvar* containing the smoothed values of *yvar*.

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Smoothed line

`lineopts(`*cline_options*`)` affects the rendition of the lowess-smoothed line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall, By

twoway_options are any of the options documented in [G-3] ***twoway_options***. These include options for titling the graph (see [G-3] ***title_options***), options for saving the graph to disk (see [G-3] ***saving_option***), and the `by()` option (see [G-3] ***by_option***).

Remarks

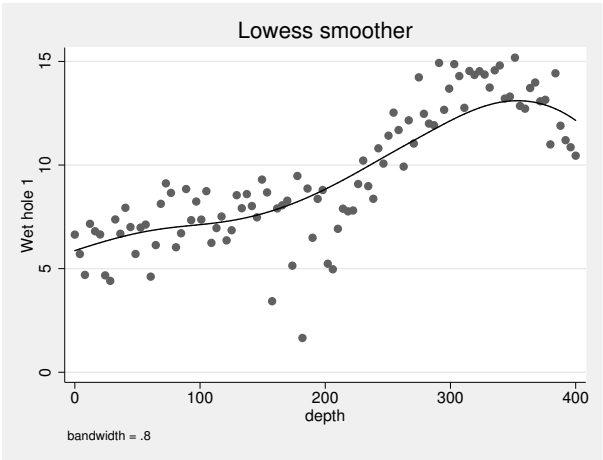
By default, `lowess` provides locally weighted scatterplot smoothing. The basic idea is to create a new variable (*newvar*) that, for each *yvar* y_i, contains the corresponding smoothed value. The smoothed values are obtained by running a regression of *yvar* on *xvar* by using only the data (x_i, y_i) and a few of the data near this point. In `lowess`, the regression is weighted so that the central point (x_i, y_i) gets the highest weight and points that are farther away (based on the distance $|x_j - x_i|$) receive less weight. The estimated regression line is then used to predict the smoothed value $\widehat{y}_i$ for y_i only. The procedure is repeated to obtain the remaining smoothed values, which means that a separate weighted regression is performed for every point in the data.

Lowess is a desirable smoother because of its locality—it tends to follow the data. Polynomial smoothing methods, for instance, are global in that what happens on the extreme left of a scatterplot can affect the fitted values on the extreme right.

Example 1

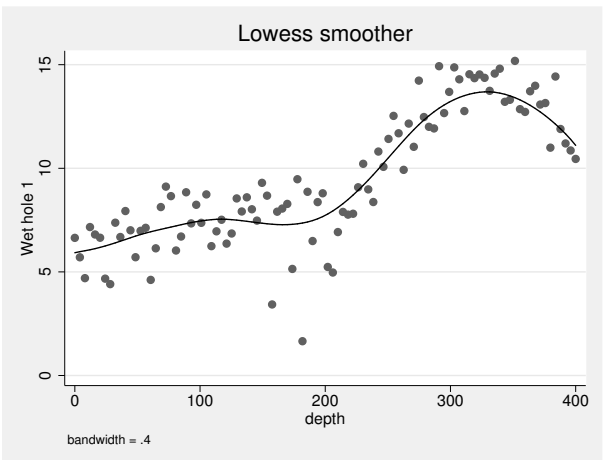
The amount of smoothing is affected by `bwidth(#)`. You are warned to experiment with different values. For instance,

```
. use http://www.stata-press.com/data/r12/lowess1
(example data for lowess)
. lowess h1 depth
```



Now compare that with

```
. lowess h1 depth, bwidth(.4)
```

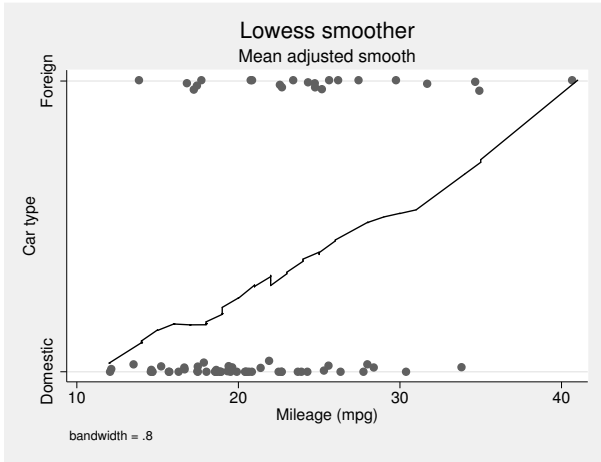


In the first case, the default bandwidth of 0.8 is used, meaning that 80% of the data are used in smoothing each point. In the second case, we explicitly specified a bandwidth of 0.4. Smaller bandwidths follow the original data more closely.

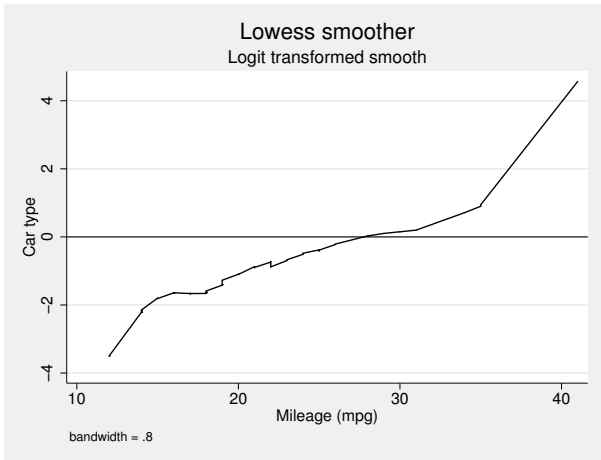
Example 2

Two `lowess` options are especially useful with binary (0/1) data: `adjust` and `logit`. `adjust` adjusts the resulting curve (by multiplication) so that the mean of the smoothed values is equal to the mean of the unsmoothed values. `logit` specifies that the smoothed curve be in terms of the log of the odds ratio:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. lowess foreign mpg, ylabel(0 "Domestic" 1 "Foreign") jitter(5) adjust
```



```
. lowess foreign mpg, logit yline(0)
```



With binary data, if you do not use the `logit` option, it is a good idea to specify `graph`'s `jitter()` option; see [G-2] **graph twoway scatter**. Because the underlying data (whether the car was manufactured outside the United States here) take on only two values, raw data points are more likely to be on top of each other, thus making it impossible to tell how many points there are. `graph`'s `jitter()` option adds some noise to the data to shift the points around. This noise affects only the location of points on the graph, not the lowess curve.

When you specify the `logit` option, the display of the raw data is suppressed.

◁

❑ Technical note

`lowess` can be used for more than just lowess smoothing. Lowess can be usefully thought of as a combination of two smoothing concepts: the use of predicted values from regression (rather than means) for imputing a smoothed value and the use of the tricube weighting function (rather than a constant weighting function). `lowess` allows you to combine these concepts freely. You can use line smoothing without weighting (specify `noweight`), mean smoothing with tricube weighting (specify `mean`), or mean smoothing without weighting (specify `mean` and `noweight`).

❑

Methods and formulas

`lowess` is implemented as an ado-file.

Let y_i and x_i be the two variables, and assume that the data are ordered so that $x_i \leq x_{i+1}$ for $i = 1, \ldots, N-1$. For each y_i, a smoothed value y_i^s is calculated.

The subset used in calculating y_i^s is indices $i_- = \max(1, i-k)$ through $i_+ = \min(i+k, N)$, where $k = \lfloor (N \times \texttt{bwidth} - 0.5)/2 \rfloor$. The weights for each of the observations between $j = i_-, \ldots, i_+$ are either 1 (`noweight`) or the tricube (default),

$$w_j = \left\{ 1 - \left(\frac{|x_j - x_i|}{\Delta} \right)^3 \right\}^3$$

where $\Delta = 1.0001 \max(x_{i_+} - x_i, x_i - x_{i_-})$. The smoothed value y_i^s is then the (weighted) mean or the (weighted) regression prediction at x_i.

William Swain Cleveland (1943–) studied mathematics and statistics at Princeton and Yale. He worked for several years at Bell Labs in New Jersey and now teaches statistics and computer science at Purdue. He has made key contributions in many areas of statistics, including graphics and data visualization, time series, environmental applications, and analysis of Internet traffic data.

Acknowledgment

`lowess` is a modified version of a command originally written by Patrick Royston of the MRC Clinical Trials Unit, London.

Statistics > Nonparametric analysis > Local polynomial smoothing

Description

lpoly performs a kernel-weighted local polynomial regression of *yvar* on *xvar* and displays a graph of the smoothed values with (optional) confidence bands.

Options

Main

kernel(*kernel*) specifies the kernel function for use in calculating the weighted local polynomial estimate. The default is kernel(epanechnikov).

bwidth(*#* | *varname*) specifies the half-width of the kernel—the width of the smoothing window around each point. If bwidth() is not specified, a rule-of-thumb (ROT) bandwidth estimator is calculated and used. A local variable bandwidth may be specified in *varname*, in conjunction with an explicit smoothing grid using the at() option.

degree(*#*) specifies the degree of the polynomial to be used in the smoothing. The default is degree(0), meaning local-mean smoothing.

generate([*newvar*$_x$] *newvar*$_s$) stores the smoothing grid in *newvar*$_x$ and the smoothed values in *newvar*$_s$. If at() is not specified, then both *newvar*$_x$ and *newvar*$_s$ must be specified. Otherwise, only *newvar*$_s$ is to be specified.

n(*#*) specifies the number of points at which the smooth is to be calculated. The default is $\min(N, 50)$, where N is the number of observations.

at(*varname*) specifies a variable that contains the values at which the smooth should be calculated. By default, the smoothing is done on an equally spaced grid, but you can use at() to instead perform the smoothing at the observed x's, for example. This option also allows you to more easily obtain smooths for different variables or different subsamples of a variable and then overlay the estimates for comparison.

nograph suppresses drawing the graph of the estimated smooth. This option is often used with the generate() option.

noscatter suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.

SE/CI

`ci` plots confidence bands, using the confidence level specified in `level()`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`se(`*newvar*`)` stores the estimates of the standard errors in *newvar*. This option requires specifying `generate()` or `at()`.

`pwidth(#)` specifies the pilot bandwidth to be used for standard-error computations. The default is chosen to be 1.5 times the value of the ROT bandwidth selector. If you specify `pwidth()` without specifying `se()` or `ci`, then the `ci` option is assumed.

`var(#` | *varname*`)` specifies an estimate of a constant residual variance or a variable containing estimates of the residual variances at each grid point required for standard-error computation. By default, the residual variance at each smoothing point is estimated by the normalized weighted residual sum of squares obtained from locally fitting a polynomial of order $p + 2$, where p is the degree specified in `degree()`. `var(`*varname*`)` is allowed only if `at()` is specified. If you specify `var()` without specifying `se()` or `ci`, then the `ci` option is assumed.

Scatterplot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Smoothed line

`lineopts(`*cline_options*`)` affects the rendition of the smoothed line; see [G-3] ***cline_options***.

CI plot

`ciopts(`*cline_options*`)` affects the rendition of the confidence bands; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Remarks are presented under the following headings:

Introduction
Local polynomial smoothing
Choice of a bandwidth
Confidence bands

Introduction

The last 25 years or so has seen a significant outgrowth in the literature on scatterplot smoothing, otherwise known as univariate nonparametric regression. Of most appeal is the idea of making no assumptions about the functional form for the expected value of a response given a regressor, but instead allowing the data to "speak for themselves". Various methods and estimators fall into the category of nonparametric regression, including local mean smoothing as described independently by Nadaraya (1964) and Watson (1964), the Gasser and Müller (1979) estimator, locally weighted scatterplot smoothing (LOWESS) as described by Cleveland (1979), wavelets (for example, Donoho [1995]), and splines (Eubank 1999), to name a few. Much of the vast literature focuses on automating the amount of smoothing to be performed and dealing with the bias/variance tradeoff inherent to this type of estimation. For example, for Nadaraya–Watson the amount of smoothing is controlled by choosing a *bandwidth*.

Smoothing via local polynomials is by no means a new idea but instead one that has been rediscovered in recent years in articles such as Fan (1992). A natural extension of the local mean smoothing of Nadaraya–Watson, local polynomial regression involves fitting the response to a polynomial form of the regressor via locally weighted least squares. Higher-order polynomials have better bias properties than the zero-degree local polynomials of the Nadaraya–Watson estimator; in general, higher-order polynomials do not require bias adjustment at the boundary of the regression space. For a definitive reference on local polynomial smoothing, see Fan and Gijbels (1996).

Local polynomial smoothing

Consider a set of scatterplot data $\{(x_1, y_1), \ldots, (x_n, y_n)\}$ from the model

$$y_i = m(x_i) + \sigma(x_i)\epsilon_i \tag{1}$$

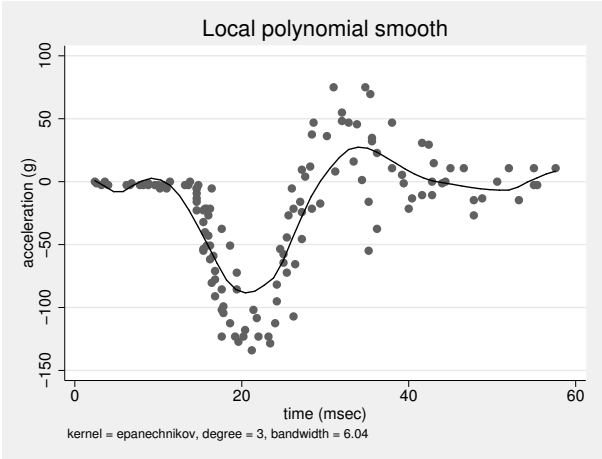
for some unknown mean and variance functions $m(\cdot)$ and $\sigma^2(\cdot)$, and symmetric errors ϵ_i with $E(\epsilon_i) = 0$ and $\mathrm{Var}(\epsilon_i) = 1$. The goal is to estimate $m(x_0) = E[Y|X = x_0]$, making no assumption about the functional form of $m(\cdot)$.

`lpoly` estimates $m(x_0)$ as the constant term (intercept) of a regression, weighted by the kernel function specified in `kernel()`, of *yvar* on the polynomial terms $(xvar - x_0), (xvar - x_0)^2, \ldots, (xvar - x_0)^p$ for each smoothing point x_0. The degree of the polynomial, p, is specified in `degree()`, the amount of smoothing is controlled by the bandwidth specified in `bwidth()`, and the chosen kernel function is specified in `kernel()`.

▷ Example 1

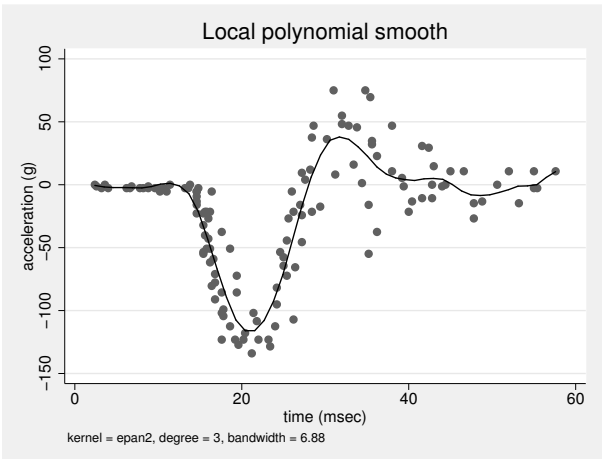
Consider the motorcycle data as examined (among other places) in Fan and Gijbels (1996). The data consist of 133 observations and measure the acceleration (`accel` measured in grams [g]) of a dummy's head during impact over time (`time` measured in milliseconds). For these data, we use `lpoly` to fit a local cubic polynomial with the default bandwidth (obtained using the ROT method) and the default Epanechnikov kernel.

```
. use http://www.stata-press.com/data/r12/motorcycle
(Motorcycle data from Fan & Gijbels (1996))
. lpoly accel time, degree(3)
```



The default bandwidth and kernel settings do not provide a satisfactory fit in this example. To improve the fit, we can either supply a different bandwidth by using the `bwidth()` option or specify a different kernel by using the `kernel()` option. For example, using the alternative Epanechnikov kernel, `kernel(epan2)`, below provides a better fit for these data.

```
. lpoly accel time, degree(3) kernel(epan2)
```



◁

❑ Technical note

`lpoly` allows specifying in `degree()` both odd and even orders of the polynomial to be used for the smoothing. However, the odd-order, $2k+1$, polynomial approximations are preferable. They have

an extra parameter compared with the even-order, $2k$, approximations, which leads to a significant bias reduction and there is no increase of variability associated with adding this extra parameter. Using an odd order when estimating the regression function is therefore usually sufficient. For a more thorough discussion, see Fan and Gijbels (1996).

❑

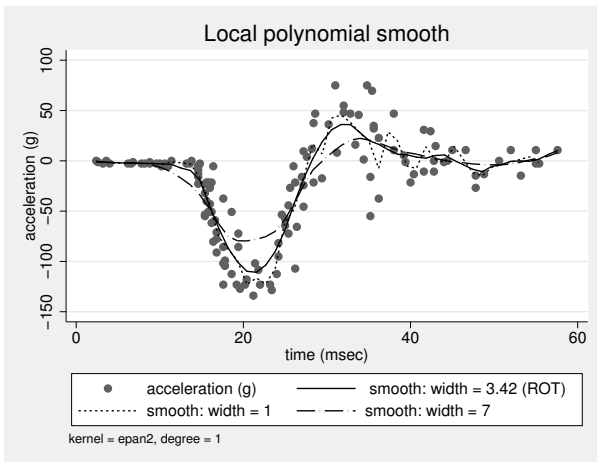
Choice of a bandwidth

The choice of a bandwidth is crucial for many smoothing techniques, including local polynomial smoothing. In general, using a large bandwidth gives smooths with a large bias, whereas a small bandwidth may result in highly variable smoothed values. Various techniques exist for optimal bandwidth selection. By default, `lpoly` uses the ROT method to estimate the bandwidth used for the smoothing; see *Methods and formulas* for details.

▷ Example 2

Using the `motorcycle` data, we demonstrate how a local linear polynomial fit changes using different bandwidths.

```
. lpoly accel time, degree(1) kernel(epan2) bwidth(1) generate(at smooth1)
> nograph
. lpoly accel time, degree(1) kernel(epan2) bwidth(7) at(at) generate(smooth2)
> nograph
. label variable smooth1 "smooth: width = 1"
. label variable smooth2 "smooth: width = 7"
. lpoly accel time, degree(1) kernel(epan2) at(at) addplot(line smooth* at)
> legend(label(2 "smooth: width = 3.42 (ROT)")) note("kernel = epan2, degree = 1")
```

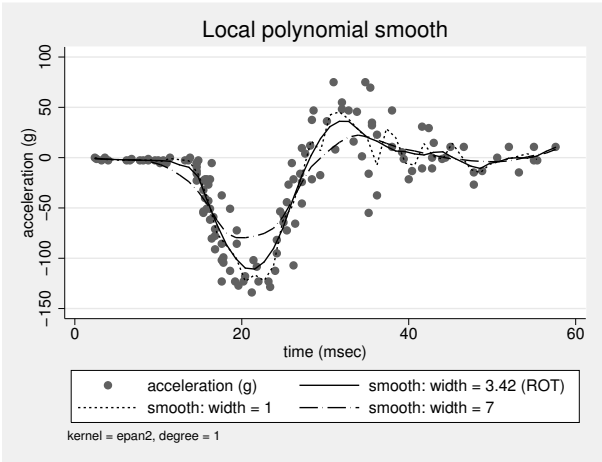


From this graph, we can see that the local linear polynomial fit with larger bandwidth (`width = 7`) corresponds to a smoother line but fails to fit the curvature of the scatterplot data. The smooth obtained using the width equal to one seems to fit most data points, but the corresponding line has several spikes indicating larger variability. The smooth obtained using the ROT bandwidth estimator seems to have a good tradeoff between the fit and variability in this example.

In the above, we also demonstrated how the `generate()` and `addplot()` options may be used to produce overlaid plots obtained from `lpoly` with different options. The `nograph` option saves time when you need to save only results with `generate()`.

However, to avoid generating variables manually, one can use `twoway lpoly` instead; see [G-2] **graph twoway lpoly** for more details.

```
. twoway scatter accel time ||
>         lpoly accel time, degree(1) kernel(epan2) lpattern(solid) ||
>         lpoly accel time, degree(1) kernel(epan2) bwidth(1)       ||
>         lpoly accel time, degree(1) kernel(epan2) bwidth(7)       ||
>     , legend(label(2 "smooth: width = 3.42 (ROT)") label(3 "smooth: width = 1")
>              label(4 "smooth: width = 7"))
>       title("Local polynomial smooth") note("kernel = epan2, degree = 1")
>       xtitle("time (msec)") ytitle("acceleration (g)")
```



The ROT estimate is commonly used as an initial guess for the amount of smoothing; this approach may be sufficient when the choice of a bandwidth is less important. In other cases, you can pick your own bandwidth.

When the shape of the regression function has a combination of peaked and flat regions, a variable bandwidth may be preferable over the constant bandwidth to allow for different degrees of smoothness in different regions. The `bwidth()` option allows you to specify the values of the local variable bandwidths as those stored in a variable in your data.

Similar issues with bias and variability arise when choosing a pilot bandwidth (the `pwidth()` option) used to compute standard errors of the local polynomial smoother. The default value is chosen to be $1.5 \times$ ROT. For a review of methods for pilot bandwidth selection, see Fan and Gijbels (1996).

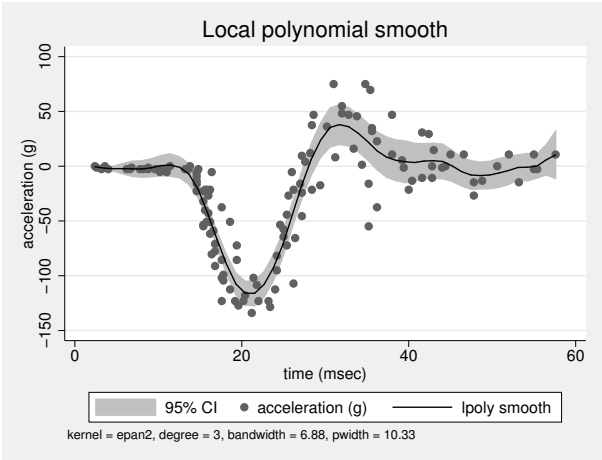
Confidence bands

The established asymptotic normality of the local polynomial estimators under certain conditions allows the construction of approximate confidence bands. `lpoly` offers the `ci` option to plot these bands.

▷ Example 3

Let us plot the confidence bands for the local polynomial fit from example 1.

```
. lpoly accel time, degree(3) kernel(epan2) ci
```



You can obtain graphs with overlaid confidence bands by using `twoway lpolyci`; see [G-2] **graph twoway lpolyci** for examples.

◁

Constructing the confidence intervals involves computing standard errors obtained by taking a square root of the estimate of the conditional variance of the local polynomial estimator at each grid point x_0. Estimating the conditional variance requires fitting a polynomial of a higher order locally by using a different bandwidth, the pilot bandwidth. The value of the pilot bandwidth may be supplied by using `pwidth()`. By default, the value of $1.5 \times$ ROT is used. Also, estimates of the residual variance $\sigma^2(x_0)$ at each grid point, x_0, are required to obtain the estimates of the conditional variances. These estimates may be supplied by using the `var()` option. By default, they are computed using the normalized weighted residual sum of squares from a local polynomial fit of a higher order. See *Methods and formulas* for details. The standard errors may be saved by using `se()`.

Saved results

`lpoly` saves the following in `r()`:

Scalars

`r(degree)`	smoothing polynomial degree	`r(bwidth)`	bandwidth of the smooth
`r(ngrid)`	number of successful regressions	`r(pwidth)`	pilot bandwidth
`r(N)`	sample size		

Macros

`r(kernel)`	name of kernel

Methods and formulas

`lpoly` is implemented as an ado-file.

Consider model (1), written in matrix notation,

$$\mathbf{y} = m(\mathbf{x}) + \epsilon$$

where $\mathbf{y}$ and $\mathbf{x}$ are the $n \times 1$ vectors of scatterplot values, ϵ is the $n \times 1$ vector of errors with zero mean and covariance matrix $\mathbf{\Sigma} = \text{diag}\{\sigma(x_i)\}\mathbf{I}_n$, and $m()$ and $\sigma()$ are some unknown functions. Define $m(x_0) = E[Y|X = x_0]$ and $\sigma^2(x_0) = \text{Var}[Y|X = x_0]$ to be the conditional mean and conditional variance of random variable Y (residual variance), respectively, for some realization x_0 of random variable X.

The method of local polynomial smoothing is based on the approximation of $m(x)$ locally by a pth order polynomial in $(x - x_0)$ for some x in the neighborhood of x_0. For the scatterplot data $\{(x_1, y_1), \ldots, (x_n, y_n)\}$, the pth-order local polynomial smooth $\widehat{m}(x_0)$ is equal to $\widehat{\beta}_0$, an estimate of the intercept of the weighted linear regression,

$$\widehat{\beta} = (\mathbf{X}^T\mathbf{W}\mathbf{X})^{-1}\mathbf{X}^T\mathbf{W}\mathbf{y} \tag{2}$$

where $\widehat{\beta} = (\widehat{\beta}_0, \widehat{\beta}_1, \ldots, \widehat{\beta}_p)^T$ is the vector of estimated regression coefficients (with $\{\widehat{\beta}_j = (j!)^{-1}\widehat{m}^{(j)}(x)|_{x=x_0},\ j = 0, \ldots, p\}$ also representing estimated coefficients from a corresponding Taylor expansion); $\mathbf{X} = \{(x_i - x_0)^j\}_{i,j=1,0}^{n,p}$ is a design matrix; and $\mathbf{W} = \text{diag}\{K_h(x_i - x_0)\}_{n\times n}$ is a weighting matrix with weights $K_h(\cdot)$ defined as $K_h(x) = h^{-1}K(x/h)$, with $K(\cdot)$ being a kernel function and h defining a bandwidth. The kernels are defined in *Methods and formulas* of [R] **kdensity**.

The default bandwidth is obtained using the ROT method of bandwidth selection. The ROT bandwidth is the plugin estimator of the asymptotically optimal constant bandwidth. This is the bandwidth that minimizes the conditional weighted mean integrated squared error. The ROT plugin bandwidth selector for the smoothing bandwidth h is defined as follows; assuming constant residual variance $\sigma^2(x_0) = \sigma^2$ and odd degree p:

$$\widehat{h} = C_{0,p}(K)\left[\frac{\widehat{\sigma}^2 \int w_0(x)dx}{n\int\{\widehat{m}^{(p+1)}(x)\}^2 w_0(x)f(x)dx}\right]^{1/(2p+3)} \tag{3}$$

where $C_{0,p}(K)$ is a constant, as defined in Fan and Gijbels (1996), that depends on the kernel function $K(\cdot)$, and the degree of a polynomial p and w_0 is chosen to be an indicator function on the interval $[\min_{\mathbf{x}} + 0.05 \times \text{range}_{\mathbf{x}}, \max_{\mathbf{x}} - 0.05 \times \text{range}_{\mathbf{x}}]$ with $\min_{\mathbf{x}}$, $\max_{\mathbf{x}}$, and $\text{range}_{\mathbf{x}}$ being, respectively, the minimum, maximum, and the range of $\mathbf{x}$. To obtain the estimates of a constant residual variance, $\widehat{\sigma}^2$, and $(p+1)$th order derivative of $m(x)$, denoted as $\widehat{m}^{(p+1)}(x)$, a polynomial in $\mathbf{x}$ of order $(p+3)$ is fit globally to $\mathbf{y}$. $\widehat{\sigma}^2$ is estimated as a standardized residual sum of squares from this fit.

The expression for the asymptotically optimal constant bandwidth used in constructing the ROT bandwidth estimator is derived for the odd-order polynomial approximations. For even-order polynomial fits the expression would depend not only on $m^{(p+1)}(x)$ but also on $m^{(p+2)}(x)$ and the design density and its derivative, $f(x)$ and $f'(x)$. Therefore, the ROT bandwidth selector would require estimation of these additional quantities. Instead, for an even-degree p of the local polynomial, `lpoly` uses the value of the ROT estimator (3) computed using degree $p + 1$. As such, for even degrees this is not a plugin estimator of the asymptotically optimal constant bandwidth.

The estimates of the conditional variance of local polynomial estimators are obtained using

$$\widehat{\mathrm{Var}}\{\widehat{m}(x_0)|X=x_0\} = \widehat{\sigma}^2_m(x_0) = (\mathbf{X}^T\mathbf{W}\mathbf{X})^{-1}(\mathbf{X}^T\mathbf{W}^2\mathbf{X})(\mathbf{X}^T\mathbf{W}\mathbf{X})^{-1}\widehat{\sigma}^2(x_0) \qquad (4)$$

where $\widehat{\sigma}^2(x_0)$ is estimated by the normalized weighted residual sum of squares from the $(p+2)$th order polynomial fit using pilot bandwidth $h^\star$.

When the bias is negligible the normal-approximation method yields a $(1-\alpha)\times 100\%$ confidence interval for $m(x_0)$,

$$\left\{\widehat{m}(x_0) - z_{(1-\alpha/2)}\widehat{\sigma}_m(x_0),\ \widehat{m}(x_0) + z_{(1-\alpha/2)}\widehat{\sigma}_m(x_0)\right\}$$

where $z_{(1-\alpha/2)}$ is the $(1-\alpha/2)$th quantile of the standard Gaussian distribution, and $\widehat{m}(x_0)$ and $\widehat{\sigma}_m(x_0)$ are as defined in (2) and (4), respectively.

Title

lrtest — Likelihood-ratio test after estimation

Syntax

`lrtest` *modelspec*$_1$ [*modelspec*$_2$] [`,` *options*]

where *modelspec* is

name | `.` | `(`*namelist*`)`

where *name* is the name under which estimation results were saved using `estimates store` (see [R] **estimates store**), and "`.`" refers to the last estimation results, whether or not these were already stored.

options	Description
`stats`	display statistical information about the two models
`dir`	display descriptive information about the two models
`df(#)`	override the automatic degrees-of-freedom calculation; seldom used
`force`	force testing even when apparently invalid

Menu

Statistics > Postestimation > Tests > Likelihood-ratio test

Description

`lrtest` performs a likelihood-ratio test of the null hypothesis that the parameter vector of a statistical model satisfies some smooth constraint. To conduct the test, both the unrestricted and the restricted models must be fit using the maximum likelihood method (or some equivalent method), and the results of at least one must be stored using `estimates store`; see [R] **estimates store**.

modelspec$_1$ and *modelspec*$_2$ specify the restricted and unrestricted model in any order. *modelspec*$_1$ and *modelspec*$_2$ cannot have names in common; for example, `lrtest (A B C) (C D E)` is not allowed because both model specifications include `C`. If *modelspec*$_2$ is not specified, the last estimation result is used; this is equivalent to specifying *modelspec*$_2$ as a period (`.`).

`lrtest` supports composite models specified by a parenthesized list of model names. In a composite model, we assume that the log likelihood and dimension (number of free parameters) of the full model are obtained as the sum of the log-likelihood values and dimensions of the constituting models.

`lrtest` provides an important alternative to `test` (see [R] **test**) for models fit via maximum likelihood or equivalent methods.

Options

`stats` displays statistical information about the unrestricted and restricted models, including the information indices of Akaike and Schwarz.

`dir` displays descriptive information about the unrestricted and restricted models; see `estimates dir` in [R] **estimates store**.

`df(#)` is seldom specified; it overrides the automatic degrees-of-freedom calculation.

`force` forces the likelihood-ratio test calculations to take place in situations where `lrtest` would normally refuse to do so and issue an error. Such situations arise when one or more assumptions of the test are violated, for example, if the models were fit with `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweights`; when the dependent variables in the two models differ; when the null log likelihoods differ; when the samples differ; or when the estimation commands differ. If you use the `force` option, there is no guarantee as to the validity or interpretability of the resulting test.

Remarks

The standard way to use `lrtest` is to do the following:

1. Fit either the restricted model or the unrestricted model by using one of Stata's estimation commands and then store the results using `estimates store` *name*.
2. Fit the alternative model (the unrestricted or restricted model) and then type '`lrtest` *name* `.`'. `lrtest` determines for itself which of the two models is the restricted model by comparing the degrees of freedom.

Often you may want to store the alternative model with `estimates store` $name_2$, for instance, if you plan additional tests against models yet to be fit. The likelihood-ratio test is then obtained as `lrtest` *name* $name_2$.

Remarks are presented under the following headings:

Nested models
Composite models

Nested models

`lrtest` may be used with any estimation command that reports a log likelihood, including `heckman`, `logit`, `poisson`, `stcox`, and `streg`. You must check that one of the model specifications implies a statistical model that is *nested within* the model implied by the other specification. Usually, this means that both models are fit with the same estimation command (for example, both are fit by `logit`, with the same dependent variables) and that the set of covariates of one model is a subset of the covariates of the other model. Second, `lrtest` is valid only for models that are fit by maximum likelihood or by some equivalent method, so it does not apply to models that were fit with probability weights or clusters. Specifying the `vce(robust)` option similarly would indicate that you are worried about the valid specification of the model, so you would not use `lrtest`. Third, `lrtest` assumes that under the null hypothesis, the test statistic is (approximately) distributed as chi-squared. This assumption is not true for likelihood-ratio tests of "boundary conditions", such as tests for the presence of overdispersion or random effects (Gutierrez, Carter, and Drukker 2001).

▷ Example 1

We have data on infants born with low birthweights along with the characteristics of the mother (Hosmer and Lemeshow 2000; see also [R] **logistic**). We fit the following model:

```
. use http://www.stata-press.com/data/r12/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
Logistic regression                               Number of obs   =        189
                                                  LR chi2(8)      =      33.22
                                                  Prob > chi2     =     0.0001
Log likelihood =   -100.724                       Pseudo R2       =     0.1416

------------------------------------------------------------------------------
         low | Odds Ratio   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         age |   .9732636   .0354759    -0.74   0.457     .9061578    1.045339
         lwt |   .9849634   .0068217    -2.19   0.029     .9716834    .9984249
             |
        race |
          2  |   3.534767   1.860737     2.40   0.016     1.259736    9.918406
          3  |   2.368079   1.039949     1.96   0.050     1.001356    5.600207
             |
       smoke |   2.517698    1.00916     2.30   0.021     1.147676    5.523162
         ptl |   1.719161   .5952579     1.56   0.118     .8721455    3.388787
          ht |   6.249602   4.322408     2.65   0.008     1.611152    24.24199
          ui |     2.1351   .9808153     1.65   0.099     .8677528      5.2534
       _cons |   1.586014   1.910496     0.38   0.702     .1496092    16.8134
------------------------------------------------------------------------------
```

We now wish to test the constraint that the coefficients on `age`, `lwt`, `ptl`, and `ht` are all zero or, equivalently here, that the odds ratios are all 1. One solution is to type

```
. test age lwt ptl ht
 ( 1)  [low]age = 0
 ( 2)  [low]lwt = 0
 ( 3)  [low]ptl = 0
 ( 4)  [low]ht = 0
           chi2(  4) =   12.38
         Prob > chi2 =    0.0147
```

This test is based on the inverse of the information matrix and is therefore based on a quadratic approximation to the likelihood function; see [R] **test**. A more precise test would be to refit the model, applying the proposed constraints, and then calculate the likelihood-ratio test.

We first save the current model:

```
. estimates store full
```

We then fit the constrained model, which here is the model omitting `age`, `lwt`, `ptl`, and `ht`:

```
. logistic low i.race smoke ui
Logistic regression                               Number of obs   =        189
                                                  LR chi2(4)      =      18.80
                                                  Prob > chi2     =     0.0009
Log likelihood = -107.93404                       Pseudo R2       =     0.0801

------------------------------------------------------------------------------
         low | Odds Ratio   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
        race |
          2  |   3.052746   1.498087     2.27   0.023     1.166747    7.987382
          3  |   2.922593   1.189229     2.64   0.008     1.316457    6.488285
             |
       smoke |   2.945742   1.101838     2.89   0.004     1.415167    6.131715
          ui |   2.419131   1.047359     2.04   0.041     1.035459    5.651788
       _cons |   .1402209   .0512295    -5.38   0.000     .0685216    .2869447
------------------------------------------------------------------------------
```

That done, `lrtest` compares this model with the model we previously saved:

```
. lrtest full .
Likelihood-ratio test                                 LR chi2(4)  =     14.42
(Assumption: . nested in full)                        Prob > chi2 =    0.0061
```

Let's compare results. `test` reported that `age`, `lwt`, `ptl`, and `ht` were jointly significant at the 1.5% level; `lrtest` reports that they are significant at the 0.6% level. Given the quadratic approximation made by `test`, we could argue that `lrtest`'s results are more accurate.

`lrtest` explicates the assumption that, from a comparison of the degrees of freedom, it has assessed that the last fit model (`.`) is nested within the model stored as `full`. In other words, `full` is the unconstrained model and `.` is the constrained model.

The names in "`(Assumption: . nested in full)`" are actually links. Click on a name, and the results for that model are replayed.

◁

Aside: The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; see [R] **nestreg**. In the previous example, we fit a full `logistic` model, used `estimates store` to store the `full` model, fit a constrained `logistic` model, and used `lrtest` to report a likelihood-ratio test between two models. To do this with one call to `nestreg`, use the `lrtable` option.

❑ Technical note

`lrtest` determines the degrees of freedom of a model as the rank of the (co)variance matrix `e(V)`. There are two issues here. First, the *numerical* determination of the rank of a matrix is a subtle problem that can, for instance, be affected by the scaling of the variables in the model. The rank of a matrix depends on the number of (independent) linear combinations of coefficients that sum exactly to zero. In the world of numerical mathematics, it is hard to tell whether a very small number is really nonzero or is a real zero that happens to be slightly off because of roundoff error from the finite precision with which computers make floating-point calculations. Whether a small number is being classified as one or the other, typically on the basis of a threshold, affects the determined degrees of freedom. Although Stata generally makes sensible choices, it is bound to make mistakes occasionally. The moral of this story is to make sure that the calculated degrees of freedom are as you expect before interpreting the results.

❑

❑ Technical note

A second issue involves `regress` and related commands such as `anova`. Mainly for historical reasons, `regress` does not treat the residual variance, σ^2, the same way that it treats the regression coefficients. Type `estat vce` after `regress`, and you will see the regression coefficients, not $\widehat{\sigma}^2$. Most estimation commands for models with ancillary parameters (for example, `streg` and `heckman`) treat all parameters as equals. There is nothing technically wrong with `regress` here; we are usually focused on the regression coefficients, and their estimators are uncorrelated with $\widehat{\sigma}^2$. But, formally, σ^2 adds a degree of freedom to the model, which does not matter if you are comparing two regression models by a likelihood-ratio test. This test depends on the difference in the degrees of freedom, and hence being "off by 1" in each does not matter. But, if you are comparing a regression model with a larger model—for example, a heteroskedastic regression model fit by `arch`—the automatic determination of the degrees of freedom is incorrect, and you must specify the `df(#)` option.

❑

Example 2

Returning to the low-birthweight data in the example 1, we now wish to test that the coefficient on `2.race` is equal to that on `3.race`. The base model is still stored under the name `full`, so we need only fit the constrained model and perform the test. With z as the index of the logit model, the base model is

$$z = \beta_0 + \beta_1\texttt{age} + \beta_2\texttt{lwt} + \beta_3\texttt{2.race} + \beta_4\texttt{3.race} + \cdots$$

If $\beta_3 = \beta_4$, this can be written as

$$z = \beta_0 + \beta_1\texttt{age} + \beta_2\texttt{lwt} + \beta_3(\texttt{2.race} + \texttt{3.race}) + \cdots$$

We can fit the constrained model as follows:

```
. constraint 1 2.race = 3.race
. logistic low age lwt i.race smoke ptl ht ui, constraints(1)
Logistic regression                                     Number of obs   =        189
                                                        Wald chi2(7)    =      25.17
Log likelihood =  -100.9997                             Prob > chi2     =     0.0007
 ( 1)  [low]2.race - [low]3.race = 0
```

low	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.9716799	.0352638	-0.79	0.429	.9049649	1.043313
lwt	.9864971	.0064627	-2.08	0.038	.9739114	.9992453
race						
2	2.728186	1.080207	2.53	0.011	1.255586	5.927907
3	2.728186	1.080207	2.53	0.011	1.255586	5.927907
smoke	2.664498	1.052379	2.48	0.013	1.228633	5.778414
ptl	1.709129	.5924776	1.55	0.122	.8663666	3.371691
ht	6.116391	4.215585	2.63	0.009	1.58425	23.61385
ui	2.09936	.9699702	1.61	0.108	.8487997	5.192407
_cons	1.309371	1.527398	0.23	0.817	.1330839	12.8825

Comparing this model with our original model, we obtain

```
. lrtest full .
Likelihood-ratio test                                   LR chi2(1)  =      0.55
(Assumption: . nested in full)                          Prob > chi2 =    0.4577
```

By comparison, typing `test 2.race=3.race` after fitting our base model results in a significance level of 0.4572. Alternatively, we can first store the restricted model, here using the name `equal`. Next `lrtest` is invoked specifying the names of the restricted and unrestricted models (we do not care about the order). This time, we also add the option `stats` requesting a table of model statistics, including the model selection indices AIC and BIC.

```
. estimates store equal
. lrtest equal full, stats
Likelihood-ratio test                                   LR chi2(1)  =      0.55
(Assumption: equal nested in full)                      Prob > chi2 =    0.4577
```

Model	Obs	ll(null)	ll(model)	df	AIC	BIC
equal	189	.	-100.9997	8	217.9994	243.9334
full	189	-117.336	-100.724	9	219.448	248.6237

Note: N=Obs used in calculating BIC; see **[R] BIC note**

Composite models

`lrtest` supports composite models; that is, models that can be fit by fitting a series of simpler models or by fitting models on subsets of the data. Theoretically, a composite model is one in which the likelihood function, $L(\theta)$, of the parameter vector, θ, can be written as the product

$$L(\theta) = L_1(\theta_1) \times L_2(\theta_2) \times \cdots \times L_k(\theta_k)$$

of likelihood terms with $\theta = (\theta_1, \ldots, \theta_k)$ a partitioning of the full parameter vector. In such a case, the full-model likelihood $L(\theta)$ is maximized by maximizing the likelihood terms $L_j(\theta_j)$ in turn. Obviously, $\log L(\widehat{\theta}) = \sum_{j=1}^{k} \log L_j(\widehat{\theta}_j)$. The degrees of freedom for the composite model is obtained as the sum of the degrees of freedom of the constituting models.

▷ Example 3

As an example of the application of composite models, we consider a test of the hypothesis that the coefficients of a statistical model do not differ between different portions ("regimes") of the covariate space. Economists call a test for such a hypothesis a *Chow test*.

We continue the analysis of the data on children of low birthweight by using logistic regression modeling and study whether the regression coefficients are the same among the three races: white, black, and other. A likelihood-ratio Chow test can be obtained by fitting the logistic regression model for each of the races and then comparing the combined results with those of the model previously stored as `full`. Because the full model included dummies for the three races, this version of the Chow test allows the intercept of the logistic regression model to vary between the regimes (races).

```
. logistic low age lwt smoke ptl ht ui if 1.race, nolog
Logistic regression                             Number of obs   =         96
                                                LR chi2(6)      =      13.86
                                                Prob > chi2     =     0.0312
Log likelihood = -45.927061                     Pseudo R2       =     0.1311

We are now ready to perform the likelihood-ratio Chow test:

```
. lrtest (full) (white black other), stats
Likelihood-ratio test                             LR chi2(12) =       9.83
                                                  Prob > chi2 =     0.6310

Assumption: (full) nested in (white, black, other)

-----------------------------------------------------------------------------
       Model |  Obs       ll(null)   ll(model)     df          AIC         BIC
-------------+---------------------------------------------------------------
        full |  189       -117.336    -100.724      9      219.448    248.6237

       other |   67       -44.26039   -37.22844      7    88.45689    103.8897
-----------------------------------------------------------------------------
                Note:  N=Obs used in calculating BIC; see [R] BIC note
```

We cannot reject the hypothesis that the logistic regression model applies to each of the races at any reasonable significance level. By specifying the `stats` option, we can verify the degrees of freedom of the test: $12 = 7 + 7 + 7 - 9$. We can obtain the same test by fitting an expanded model with interactions between all covariates and `race`.

```
. logistic low race##c.(age lwt smoke ptl ht ui)
Logistic regression                               Number of obs   =        189

```

Applying `lrtest` for the full model against the model with all interactions yields the same test statistic and p-value as for the full model against the composite model for the three regimes. Here the specification of the model with interactions was convenient, and `logistic` had no problem computing the estimates for the expanded model. In models with more complicated likelihoods, such as Heckman's selection model (see [R] **heckman**) or complicated survival-time models (see [ST] **streg**), fitting the models with all interactions may be numerically demanding and may be much more time consuming than fitting a series of models separately for each regime.

Given the model with all interactions, we could also test the hypothesis of no differences among the regions (races) by a Wald version of the Chow test by using the `testparm` command; see [R] **test**.

```
. testparm race#c.(age lwt smoke ptl ht ui)
 ( 1)  [low]2.race#c.age = 0
 ( 2)  [low]3.race#c.age = 0
 ( 3)  [low]2.race#c.lwt = 0
 ( 4)  [low]3.race#c.lwt = 0
 ( 5)  [low]2.race#c.smoke = 0
 ( 6)  [low]3.race#c.smoke = 0
 ( 7)  [low]2.race#c.ptl = 0
 ( 8)  [low]3.race#c.ptl = 0
 ( 9)  [low]2.race#c.ht = 0
 (10)  [low]3.race#c.ht = 0
 (11)  [low]2.race#c.ui = 0
 (12)  [low]3.race#c.ui = 0
           chi2( 12) =    8.24
         Prob > chi2 =    0.7663
```

We conclude that, here, the Wald version of the Chow test is similar to the likelihood-ratio version of the Chow test.

◁

Saved results

`lrtest` saves the following in `r()`:

Scalars

`r(p)`	level of significance
`r(df)`	degrees of freedom
`r(chi2)`	LR test statistic

Programmers wishing their estimation commands to be compatible with `lrtest` should note that `lrtest` requires that the following results be returned:

`e(cmd)`	name of estimation command
`e(ll)`	log likelihood
`e(V)`	variance–covariance matrix of the estimators
`e(N)`	number of observations

`lrtest` also verifies that `e(N)`, `e(ll_0)`, and `e(depvar)` are consistent between two noncomposite models.

Methods and formulas

`lrtest` is implemented as an ado-file.

Let L_0 and L_1 be the log-likelihood values associated with the full and constrained models, respectively. The test statistic of the likelihood-ratio test is $\text{LR} = -2(L_1 - L_0)$. If the constrained model is true, LR is approximately χ^2 distributed with $d_0 - d_1$ degrees of freedom, where d_0 and d_1 are the model degrees of freedom associated with the full and constrained models, respectively (Greene 2012, 526–527).

`lrtest` determines the degrees of freedom of a model as the rank of `e(V)`, computed as the number of nonzero diagonal elements of `invsym(e(V))`.

Title

lv — Letter-value displays

Syntax

```
lv [varlist] [if] [in] [, generate tail(#)]
```

by is allowed; see [D] **by**.

Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Letter-value display

Description

lv shows a letter-value display (Tukey 1977, 44–49; Hoaglin 1983) for each variable in *varlist*. If no variables are specified, letter-value displays are shown for each numeric variable in the data.

Options

Main

generate adds four new variables to the data: _mid, containing the midsummaries; _spread, containing the spreads; _psigma, containing the pseudosigmas; and _z2, containing the squared values from a standard normal distribution corresponding to the particular letter value. If the variables _mid, _spread, _psigma, and _z2 already exist, their contents are replaced. At most, only the first 11 observations of each variable are used; the remaining observations contain missing. If *varlist* specifies more than one variable, the newly created variables contain results for the last variable specified. The generate option may not be used with the by prefix.

tail(#) indicates the inverse of the tail density through which letter values are to be displayed: 2 corresponds to the median (meaning half in each tail), 4 to the fourths (roughly the 25th and 75th percentiles), 8 to the eighths, and so on. # may be specified as 4, 8, 16, 32, 64, 128, 256, 512, or 1,024 and defaults to a value of # that has corresponding depth just greater than 1. The default is taken as 1,024 if the calculation results in a number larger than 1,024. Given the intelligent default, this option is rarely specified.

Remarks

Letter-value displays are a collection of observations drawn systematically from the data, focusing especially on the tails rather than the middle of the distribution. The displays are called letter-value displays because letters have been (almost arbitrarily) assigned to tail densities:

Letter	Tail area	Letter	Tail area
M	1/2	B	1/64
F	1/4	A	1/128
E	1/8	Z	1/256
D	1/16	Y	1/512
C	1/32	X	1/1024

Example 1

We have data on the mileage ratings of 74 automobiles. To obtain a letter-value display, we type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. lv mpg
 #      74              Mileage (mpg)
                  ------------------------------

 M      37.5 |                  20              |    spread  pseudosigma
 F        19 |          18     21.5          25 |         7    5.216359
 E        10 |          15     21.5          28 |        13    5.771728
 D       5.5 |          14    22.25        30.5 |      16.5    5.576303
 C         3 |          14     24.5          35 |        21    5.831039
 B         2 |          12     23.5          35 |        23    5.732448
 A       1.5 |          12       25          38 |        26    6.040635
         1   |          12     26.5          41 |        29     6.16562

                                                |  # below     # above
inner fence  |         7.5                 35.5 |         0           1
outer fence  |          -3                   46 |         0           0
```

The decimal points can be made to line up and thus the output made more readable by specifying a display format for the variable; see [U] **12.5 Formats: Controlling how data are displayed**.

```
. format mpg %9.2f
. lv mpg
 #      74              Mileage (mpg)
                  ------------------------------

```

At the top, the number of observations is indicated as 74. The first line shows the statistics associated with M, the letter value that puts half the density in each tail, or the median. The median has *depth* 37.5 (that is, in the ordered data, M is 37.5 observations in from the extremes) and has value 20. The next line shows the statistics associated with F or the fourths. The fourths have depth 19 (that is, in the ordered data, the lower fourth is observation 19, and the upper fourth is observation $74 - 19 + 1$), and the values of the lower and upper fourths are 18 and 25. The number in the middle is the point halfway between the fourths—called a midsummary. If the distribution were perfectly symmetric, the midsummary would equal the median. The spread is the difference between the lower and upper summaries ($25 - 18 = 7$). For fourths, half the data lie within a 7-mpg band. The pseudosigma is a calculation of the standard deviation using only the lower and upper summaries and assuming that the variable is normally distributed. If the data really were normally distributed, all the pseudosigmas would be roughly equal.

After the letter values, the line labeled with depth 1 reports the minimum and maximum values. Here the halfway point between the extremes is 26.5, which is greater than the median, indicating that 41 is more extreme than 12, at least relative to the median. And with each letter value, the

midsummaries are increasing—our data are skewed. The pseudosigmas are also increasing, indicating that the data are spreading out relative to a normal distribution, although, given the evident skewness, this elongation may be an artifact of the skewness.

At the end is an attempt to identify outliers, although the points so identified are merely outside some predetermined cutoff. Points outside the inner fence are called *outside values* or *mild outliers*. Points outside the outer fence are called *severe outliers*. The inner fence is defined as $(3/2)$IQR and the outer fence as 3IQR above and below the F summaries, where the interquartile range (IQR) is the spread of the fourths.

◁

❑ Technical note

The form of the letter-value display has varied slightly with different authors. `lv` displays appear as described by Hoaglin (1983) but as modified by Emerson and Stoto (1983), where they included the midpoint of each of the spreads. This format was later adopted by Hoaglin (1985). If the distribution is symmetric, the midpoints will all be roughly equal. On the other hand, if the midpoints vary systematically, the distribution is skewed.

The pseudosigmas are obtained from the lower and upper summaries for each letter value. For each letter value, they are the standard deviation a normal distribution would have if its spread for the given letter value were to equal the observed spread. If the pseudosigmas are all roughly equal, the data are said to have *neutral elongation*. If the pseudosigmas increase systematically, the data are said to be more elongated than a normal, that is, have thicker tails. If the pseudosigmas decrease systematically, the data are said to be less elongated than a normal, that is, have thinner tails.

Interpretation of the number of mild and severe outliers is more problematic. The following discussion is drawn from Hamilton (1991):

Obviously, the presence of any such outliers does not rule out that the data have been drawn from a normal distribution; in large datasets, there will most certainly be observations outside $(3/2)$IQR and 3IQR. Severe outliers, however, make up about two per million (0.0002%) of a normal population. In samples, they lie far enough out to have substantial effects on means, standard deviations, and other classical statistics. The 0.0002%, however, should be interpreted carefully; outliers appear more often in small samples than one might expect from population proportions because of sampling variation in estimated quartiles. Monte Carlo simulation by Hoaglin, Iglewicz, and Tukey (1986) obtained these results on the percentages and numbers of outliers in random samples from a normal population:

	percentage		number	
n	any outliers	severe	any outliers	severe
10	2.83	.362	.283	.0362
20	1.66	.074	.332	.0148
50	1.15	.011	.575	.0055
100	.95	.002	.95	.002
200	.79	.001	1.58	.002
300	.75	.001	2.25	.003
∞	.70	.0002	∞	∞

Thus the presence of any severe outliers in samples of less than 300 is sufficient to reject normality. Hoaglin, Iglewicz, and Tukey (1981) suggested the approximation $0.00698 + 0.4/n$ for the fraction of mild outliers in a sample of size n or, equivalently, $0.00698n + 0.4$ for the number of outliers.

❑

Example 2

The `generate` option adds the `_mid`, `_spread`, `_psigma`, and `_z2` variables to our data, making possible many of the diagnostic graphs suggested by Hoaglin (1985).

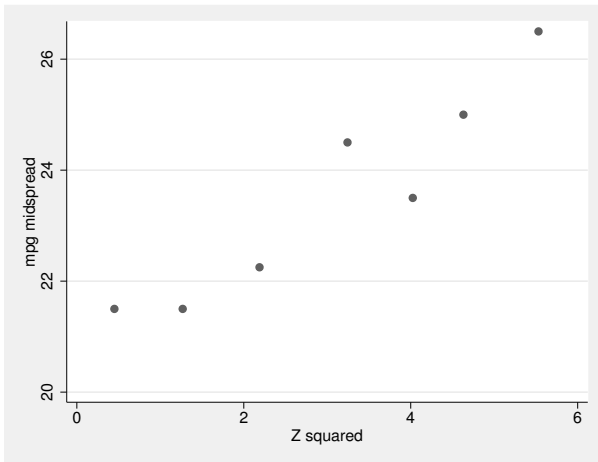
```
. lv mpg, generate
  (output omitted)
. list _mid _spread _psigma _z2 in 1/12
```

	_mid	_spread	_psigma	_z2
1.	20	.	.	.
2.	21.5	7	5.216359	.4501955
3.	21.5	13	5.771728	1.26828
4.	22.25	16.5	5.576303	2.188846
5.	24.5	21	5.831039	3.24255
6.	23.5	23	5.732448	4.024532
7.	25	26	6.040635	4.631499
8.	.	.	.	.
9.	.	.	.	.
10.	.	.	.	.
11.	26.5	29	6.16562	5.53073
12.	.	.	.	.

Observations 12 through the end are missing for these new variables. The definition of the observations is always the same. The first observation contains the M summary; the second, the F; the third, the E; and so on. Observation 11 always contains the summary for depth 1. Observations 8–10—corresponding to letter values Z, Y, and X—contain missing because these statistics were not calculated. We have only 74 observations, and their depth would be 1.

Hoaglin (1985) suggests graphing the midsummary against z^2. If the distribution is not skewed, the points in the resulting graph will be along a horizontal line:

```
. scatter _mid _z2
```



The graph clearly indicates the skewness of the distribution. We might also graph `_psigma` against `_z2` to examine elongation.

Saved results

lv saves the following in r():

Scalars

r(N)	number of observations	r(u_C)	upper 32nd
r(min)	minimum	r(l_B)	lower 64th
r(max)	maximum	r(u_B)	upper 64th
r(median)	median	r(l_A)	lower 128th
r(l_F)	lower 4th	r(u_A)	upper 128th
r(u_F)	upper 4th	r(l_Z)	lower 256th
r(l_E)	lower 8th	r(u_Z)	upper 256th
r(u_E)	upper 8th	r(l_Y)	lower 512th
r(l_D)	lower 16th	r(u_Y)	upper 512th
r(u_D)	upper 16th	r(l_X)	lower 1024th
r(l_C)	lower 32nd	r(u_X)	upper 1024th

The lower/upper 8ths, 16ths, ..., 1024ths will be defined only if there are sufficient data.

Methods and formulas

lv is implemented as an ado-file.

Let N be the number of (nonmissing) observations on x, and let $x_{(i)}$ refer to the ordered data when i is an integer. Define $x_{(i+0.5)} = (x_{(i)} + x_{(i+1)})/2$; the median is defined as $x_{\{(N+1)/2\}}$.

Define $x_{[d]}$ as the pair of numbers $x_{(d)}$ and $x_{(N+1-d)}$, where d is called the *depth*. Thus $x_{[1]}$ refers to the minimum and maximum of the data. Define $m = (N+1)/2$ as the depth of the median, $f = (\lfloor m \rfloor + 1)/2$ as the depth of the fourths, $e = (\lfloor f \rfloor + 1)/2$ as the depth of the eighths, and so on. Depths are reported on the far left of the letter-value display. The corresponding fourths of the data are $x_{[f]}$, the eighths are $x_{[e]}$, and so on. These values are reported inside the display. The middle value is defined as the corresponding midpoint of $x_{[\cdot]}$. The spreads are defined as the difference in $x_{[\cdot]}$.

The corresponding point z_i on a standard normal distribution is obtained as (Hoaglin 1985, 456–457)

$$z_i = \begin{cases} F^{-1}\{(d_i - 1/3)/(N + 1/3)\} & \text{if } d_i > 1 \\ F^{-1}\{0.695/(N + 0.390)\} & \text{otherwise} \end{cases}$$

where d_i is the depth of the letter value. The corresponding pseudosigma is obtained as the ratio of the spread to $-2z_i$ (Hoaglin 1985, 431).

Define $(F_l, F_u) = x_{[f]}$. The inner fence has cutoffs $F_l - \frac{3}{2}(F_u - F_l)$ and $F_u + \frac{3}{2}(F_u - F_l)$. The outer fence has cutoffs $F_l - 3(F_u - F_l)$ and $F_u + 3(F_u - F_l)$.

The inner-fence values reported by lv are almost equal to those used by graph, box to identify outside points. The only difference is that graph uses a slightly different definition of fourths, namely, the 25th and 75th percentiles as defined by summarize; see [R] **summarize**.

Title

margins — Marginal means, predictive margins, and marginal effects

Syntax

`margins` [*marginlist*] [*if*] [*in*] [*weight*] [`,` *response_options* *options*]

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

```
. margins i.sex i.group i.sex#i.group
. margins sex group sex#i.group
. margins sex##group
```

response_options	Description
Main	
`predict(`*pred_opt*`)`	estimate margins for `predict,` *pred_opt*
`expression(`*pnl_exp*`)`	estimate margins for *pnl_exp*
`dydx(`*varlist*`)`	estimate marginal effect of variables in *varlist*
`eyex(`*varlist*`)`	estimate elasticities of variables in *varlist*
`dyex(`*varlist*`)`	estimate semielasticity—$d(y)/d(\ln x)$
`eydx(`*varlist*`)`	estimate semielasticity—$d(\ln y)/d(x)$
`continuous`	treat factor-level indicators as continuous

options	Description
Main	
`grand`	add the overall margin; default if no *marginlist*
At	
`at(`*atspec*`)`	estimate margins at specified values of covariates
`atmeans`	estimate margins at the means of covariates
`asbalanced`	treat all factor variables as balanced
if/in/over	
`over(`*varlist*`)`	estimate margins at unique values of *varlist*
`subpop(`*subspec*`)`	estimate margins for subpopulation
Within	
`within(`*varlist*`)`	estimate margins at unique values of the nesting factors in *varlist*
SE	
`vce(delta)`	estimate SEs using delta method; the default
`vce(unconditional)`	estimate SEs allowing for sampling of covariates
`nose`	do not estimate SEs

Advanced

noweights	ignore weights specified in estimation
noesample	do not restrict margins to the estimation sample
emptycells(*empspec*)	treatment of empty cells for balanced factors
estimtolerance(*tol*)	specify numerical tolerance used to determine estimable functions; default is estimtolerance(1e-5)
noestimcheck	suppress estimability checks
force	estimate margins despite potential problems
chainrule	use the chain rule when computing derivatives
nochainrule	do not use the chain rule

Reporting

level(#)	set confidence level; default is level(95)
mcompare(*method*)	adjust for multiple comparisons; default is mcompare(noadjust)
noatlegend	suppress legend of fixed covariate values
post	post margins and their VCE as estimation results
display_options	control column formats, row spacing, and line width

method	Description
noadjust	do not adjust for multiple comparisons; the default
bonferroni [adjustall]	Bonferroni's method; adjust across all terms
sidak [adjustall]	Šidák's method; adjust across all terms
scheffe	Scheffé's method

Time-series operators are allowed if they were used in the estimation.

See at() under *Options* for a description of *atspec*.

fweights, aweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Postestimation > Marginal means and predictive margins

Statistics > Postestimation > Marginal effects

Description

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates.

The margins command estimates margins of responses for specified values of covariates and presents the results as a table.

Capabilities include estimated marginal means, least-squares means, average and conditional marginal and partial effects (which may be reported as derivatives or as elasticities), average and conditional adjusted predictions, and predictive margins.

Options

Warning: The option descriptions are brief and use jargon. Skip to Remarks if you are reading about `margins` *for the first time.*

Main

`predict(`*pred_opt*`)` and `expression(`*pnl_exp*`)` are mutually exclusive; they specify the response. If neither is specified, the response will be the default prediction that would be produced by `predict` after the underlying estimation command.

`predict(`*pred_opt*`)` specifies the option(s) to be specified with the `predict` command to produce the variable that will be used as the response. After estimation by `logistic`, you could specify `predict(xb)` to obtain linear predictions rather than the `predict` command's default, the probabilities.

`expression(`*pnl_exp*`)` specifies the response as an expression. See [R] **predictnl** for a full description of *pnl_exp*. After estimation by `logistic`, you might specify `expression(exp(predict(xb)))` to use relative odds rather than probabilities as the response. For examples, see *Example 12: Margins of a specified expression*.

`dydx(`*varlist*`)`, `eyex(`*varlist*`)`, `dyex(`*varlist*`)`, and `eydx(`*varlist*`)` request that `margins` report derivatives of the response with respect to *varlist* rather than on the response itself. `eyex()`, `dyex()`, and `eydx()` report derivatives as elasticities; see *Expressing derivatives as elasticities*.

`continuous` is relevant only when one of `dydx()` or `eydx()` is also specified. It specifies that the levels of factor variables be treated as continuous; see *Derivatives versus discrete differences*. This option is implied if there is a single-level factor variable specified in `dydx()` or `eydx()`.

`grand` specifies that the overall margin be reported. `grand` is assumed when *marginlist* is empty.

At

`at(`*atspec*`)` specifies values for covariates to be treated as fixed.

`at(age=20)` fixes covariate `age` to the value specified. `at()` may be used to fix continuous or factor covariates.

`at(age=20 sex=1)` simultaneously fixes covariates `age` and `sex` at the values specified.

`at(age=(20 30 40 50))` fixes age first at 20, then at 30, ... `margins` produces separate results for each specified value.

`at(age=(20(10)50))` does the same as `at(age=(20 30 40 50))`; that is, you may specify a numlist.

`at((mean) age (median) distance)` fixes the covariates at the summary statistics specified. `at((p25) _all)` fixes all covariates at their 25th percentile values. See *Syntax of at()* for the full list of summary-statistic modifiers.

`at((mean) _all (median) x x2=1.2 z=(1 2 3))` is read from left to right, with latter specifiers overriding former ones. Thus all covariates are fixed at their means except for `x` (fixed at its median), `x2` (fixed at 1.2), and `z` (fixed first at 1, then at 2, and finally at 3).

`at((means) _all (asobserved) x2)` is a convenient way to set all covariates except `x2` to the mean.

Multiple `at()` options can be specified, and each will produce a different set of margins.

See *Syntax of at()* for more information.

`atmeans` specifies that covariates be fixed at their means and is shorthand for `at((mean) _all)`. `atmeans` differs from `at((mean) _all)` in that `atmeans` will affect subsequent `at()` options. For instance,

```
. margins ..., atmeans  at((p25) x)  at((p75) x)
```

produces two sets of margins with both sets evaluated at the means of all covariates except `x`.

`asbalanced` is shorthand for `at((asbalanced) _factor)` and specifies that factor covariates be evaluated as though there were an equal number of observations in each level; see *Obtaining margins as though the data were balanced*. `asbalanced` differs from `at((asbalanced) _factor)` in that `asbalanced` will affect subsequent `at()` options in the same way as `atmeans` does.

if/in/over

`over(`*varlist*`)` specifies that separate sets of margins be estimated for the groups defined by *varlist*. The variables in *varlist* must contain nonnegative integer values. The variables need not be covariates in your model. When `over()` is combined with the `vce(unconditional)` option, each group is treated as a subpopulation; see [SVY] **subpopulation estimation**.

`subpop(`[*varname*] [*if*]`)` is intended for use with the `vce(unconditional)` option. It specifies that margins be estimated for the single subpopulation identified by the indicator variable or by the `if` expression or by both. Zero indicates that the observation be excluded; nonzero, that it be included; and missing value, that it be treated as outside of the population (and so ignored). See [SVY] **subpopulation estimation** for why `subpop()` is preferred to `if` expressions and `in` ranges when also using `vce(unconditional)`. If `subpop()` is used without `vce(unconditional)`, it is treated merely as an additional `if` qualifier.

Within

`within(`*varlist*`)` allows for nested designs. *varlist* contains the nesting variable(s) over which margins are to be estimated. See *Obtaining margins with nested designs*. As with `over(`*varlist*`)`, when `within(`*varlist*`)` is combined with `vce(unconditional)`, each level of the variables in *varlist* is treated as a subpopulation.

SE

`vce(delta)` and `vce(unconditional)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions and allows for correlation among the observations in the same manner as `vce(robust)` and `vce(cluster ...)`, which may have been specified with the estimation command. This method also accounts for complex survey designs if the data are `svyset`. See *Obtaining margins with survey data and representative samples*.

`nose` suppresses calculation of the VCE and standard errors. See *Requirements for model specification* for an example of the use of this option.

Advanced

noweights specifies that any weights specified on the previous estimation command be ignored by margins. By default, margins uses the weights specified on the estimator to average responses and to compute summary statistics. If weights are specified on the margins command, they override previously specified weights, making it unnecessary to specify noweights. The noweights option is not allowed after svy: estimation when the vce(unconditional) option is specified.

noesample specifies that margins not restrict its computations to the estimation sample used by the previous estimation command. See *Example 15: Margins evaluated out of sample*.

With the default delta-method VCE, noesample margins may be estimated on samples other than the estimation sample; such results are valid under the assumption that the data used are treated as being given.

You can specify noesample and vce(unconditional) together, but if you do, you should be sure that the data in memory correspond to the original e(sample). To show that you understand that, you must also specify the force option. Be aware that making the vce(unconditional) calculation on a sample different from the estimation sample would be equivalent to estimating the coefficients on one set of data and computing the scores used by the linearization on another set; see [P] **_robust**.

emptycells(strict) and emptycells(reweight) are relevant only when the asbalanced option is also specified. emptycells() specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced; see *Obtaining margins as though the data were balanced*.

emptycells(strict) is the default; it specifies that margins involving empty cells be treated as not estimable.

emptycells(reweight) specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margin estimable but changes its interpretation. emptycells(reweight) is implied when the within() option is specified.

estimtolerance(*tol*) specifies the numerical tolerance used to determine estimable functions. The default is estimtolerance(1e-5).

A linear combination of the model coefficients z is found to be not estimable if

$$\texttt{mreldif}(z,\ z \times H) > tol$$

where H is defined in *Methods and formulas*.

noestimcheck specifies that margins not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If noestimcheck is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations. See *Estimability of margins*.

force instructs margins to proceed in some situations where it would otherwise issue an error message because of apparent violations of assumptions. Do not be casual about specifying force. You need to understand and fully evaluate the statistical issues. For an example of the use of force, see *Using margins after the estimates use command*.

chainrule and nochainrule specify whether margins uses the chain rule when numerically computing derivatives. You need not specify these options when using margins after any official Stata estimator; margins will choose the appropriate method automatically.

Specify nochainrule after estimation by a user-written command. We recommend using nochainrule, even though chainrule is usually safe and is always faster. nochainrule is safer because it makes no assumptions about how the parameters and covariates join to form the response.

nochainrule is implied when the expression() option is specified.

Reporting

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.7 Specifying the width of confidence intervals.

mcompare(*method*) specifies the method for computing p-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, α_c, to achieve a prespecified experimentwise error rate, α_e.

mcompare(noadjust) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$\alpha_e \leq m\alpha_c$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

mcompare(sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the m comparisons are independent.

mcompare(scheffe) controls the experimentwise error rate using the F or χ^2 distribution with degrees of freedom equal to the rank of the term.

mcompare(*method* adjustall) specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginslist*. This option is compatible only with the bonferroni and sidak methods.

noatlegend specifies that the legend showing the fixed values of covariates be suppressed.

post causes margins to behave like a Stata estimation (e-class) command. margins posts the vector of estimated margins along with the estimated variance–covariance matrix to e(), so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use test to perform simultaneous tests of hypotheses on the margins, or you could use lincom to create linear combinations. See *Example 10: Testing margins—contrasts of margins*.

display_options: vsquish, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch.

vsquish specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

cformat(%*fmt*) specifies how to format margins, standard errors, and confidence limits in the table of estimated margins.

`pformat(%`*fmt*`)` specifies how to format p-values in the table of estimated margins.

`sformat(%`*fmt*`)` specifies how to format test statistics in the table of estimated margins.

`nolstretch` specifies that the width of the table of estimated margins not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of estimated margins up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

Glossary

Introduction

margins is a postestimation command, a command for use after you have fit a model using an estimation command such as regress or logistic, or using almost any other estimation command.

margins estimates and reports margins of responses and margins of derivatives of responses, also known as marginal effects. A margin is a statistic based on a fitted model in which some of or all the covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

Obtaining margins of responses

What we call margins of responses are also known as predictive margins, adjusted predictions, and recycled predictions. When applied to balanced data, margins of responses are also called estimated marginal means and least-squares means.

A margin is a statistic based on a fitted model calculated over a dataset in which some of or all the covariates are fixed at values different from what they really are. For instance, after a linear regression fit on males and females, the marginal mean (margin of mean) for males is the predicted mean of the dependent variable, where every observation is treated as if it represents a male; thus those observations that in fact do represent males are included, as well as those observations that represent females. The marginal mean for female would be similarly obtained by treating all observations as if they represented females.

In making the calculation, sex is treated as male or female everywhere it appears in the model. The model might be

```
. regress y age bp i.sex sex#c.age sex#c.bp
```

and then, in making the marginal calculation of the mean for males and females, margins not only accounts for the direct effect of i.sex but also for the indirect effects of sex#c.age and sex#c.bp.

The response being margined can be any statistic produced by [R] **predict**, or any expression of those statistics.

Standard errors are obtained by the delta method, at least by default. The delta method assumes that the values at which the covariates are evaluated to obtain the marginal responses are fixed. When your sample represents a population, whether you are using svy or not (see [SVY] **svy**), you can specify margins' vce(unconditional) option and margins will produce standard errors that account for the sampling variability of the covariates. Some researchers reserve the term predictive margins to describe this.

The best way to understand margins is to see some examples. You can run the following examples yourself if you type

```
. use http://www.stata-press.com/data/r12/margex
(Artificial data for margins)
```

Example 1: A simple case after regress

```
. regress y i.sex i.group
  (output omitted)
. margins sex
Predictive margins                              Number of obs   =       3000
Model VCE    : OLS
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	60.56034	.5781782	104.74	0.000	59.42713	61.69355
1	78.88236	.5772578	136.65	0.000	77.75096	80.01377

The numbers reported in the "Margin" column are average values of `y`. Based on a linear regression of `y` on `sex` and `group`, 60.6 would be the average value of `y` if everyone in the data were treated as if they were male, and 78.9 would be the average value if everyone were treated as if they were female.

Example 2: A simple case after logistic

`margins` may be used after almost any estimation command.

```
. logistic outcome i.sex i.group
  (output omitted)
. margins sex
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1286796	.0111424	11.55	0.000	.106841	.1505182
1	.1905087	.0089719	21.23	0.000	.1729241	.2080933

The numbers reported in the "Margin" column are average predicted probabilities. Based on a logistic regression of `outcome` on `sex` and `group`, 0.13 would be the average probability of `outcome` if everyone in the data were treated as if they were male, and 0.19 would be the average probability if everyone were treated as if they were female.

`margins` reports average values after `regress` and average probabilities after `logistic`. By default, `margins` makes tables of whatever it is that `predict` (see [R] **predict**) predicts by default. Alternatively, `margins` can make tables of anything that `predict` can produce if you use `margins`' `predict()` option; see *Example 11: Margins of a specified prediction*.

Example 3: Average response versus response at average

In example 2, margins reported average probabilities of outcome for sex = 0 and sex = 1. If we instead wanted the predicted probabilities evaluated at the mean of the covariates, we would specify margins' atmeans option. We previously typed

```
. logistic outcome i.sex i.group
  (output omitted)
. margins sex
  (output omitted)
```

and now we type

```
. margins sex, atmeans
Adjusted predictions                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
at           : 0.sex           =    .4993333 (mean)
               1.sex           =    .5006667 (mean)
               1.group         =    .3996667 (mean)
               2.group         =    .3726667 (mean)
               3.group         =    .2276667 (mean)
```

	Delta-method Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.0966105	.0089561	10.79	0.000	.0790569	.1141641
1	.1508362	.0118064	12.78	0.000	.127696	.1739764

The prediction at the average of the covariates is different from the average of the predictions. The first is the expected probability of a person with average characteristics, a person who, in another problem, might be 3/4 married and have 1.2 children. The second is the average of the probability among actual persons in the data.

When you specify atmeans or any other at option, margins reports the values used for the covariates in the legend above the table. margins lists the values for all the covariates, including values it may not use, in the results that follow. In this example, margins reported means for sex even though those means were not used. They were not used because we asked for the margins of sex, so sex was fixed first at 0 and then at 1.

If you wish to suppress this legend, specify the nolegend option.

Example 4: Multiple margins from one command

More than one margin can be reported by just one margins command. You can type

```
. margins sex group
```

and doing that is equivalent in terms of the output to typing

```
. margins sex
. margins group
```

When multiple margins are requested on the same command, each is estimated separately. There is, however, a difference when you also specify margins' post option. Then the variance–covariance matrix for all margins requested is posted, and that is what allows you to test equality of margins, etc. Testing equality of margins is covered in *Example 10: Testing margins—contrasts of margins*.

In any case, below we request margins for sex and for group.

```
. margins sex group
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1286796	.0111424	11.55	0.000	.106841	.1505182
1	.1905087	.0089719	21.23	0.000	.1729241	.2080933
group						
1	.2826207	.0146234	19.33	0.000	.2539593	.311282
2	.1074814	.0094901	11.33	0.000	.0888812	.1260817
3	.0291065	.0073417	3.96	0.000	.0147169	.043496

Example 5: Margins with interaction terms

The estimation command on which margins bases its calculations may contain interaction terms, such as an interaction of sex and group:

```
. logistic outcome i.sex i.group sex#group
  (output omitted)
. margins sex group
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1561738	.0132774	11.76	0.000	.1301506	.182197
1	.1983749	.0101546	19.54	0.000	.1784723	.2182776
group						
1	.3211001	.0176403	18.20	0.000	.2865257	.3556744
2	.1152127	.0099854	11.54	0.000	.0956417	.1347838
3	.0265018	.0109802	2.41	0.016	.0049811	.0480226

We fit the model by typing logistic outcome i.sex i.group sex#group, but the meaning would have been the same had we typed logistic outcome sex##group.

As mentioned in example 4, the results for sex and the results for group are calculated independently, and we would have obtained the same results had we typed margins sex followed by margins group.

The margin for male (sex = 0) is 0.16. The probability 0.16 is the average probability if everyone in the data were treated as if sex = 0, including sex = 0 in the main effect and sex = 0 in the interaction of sex with group.

Had we specified margins sex, atmeans, we would have obtained not average probabilities but the probabilities evaluated at the average. Rather than obtaining 0.16, we would have obtained 0.10

for sex = 0. The 0.10 is calculated by taking the fitted model, plugging in sex = 0 everywhere, and plugging in the average value of the group indicator variables everywhere they are used. That is, rather than treating the group indicators as being (1, 0, 0), (0, 1, 0), or (0, 0, 1) depending on observation, the group indicators are treated as being (0.40, 0.37, 0.23), which are the average values of group = 1, group = 2, and group = 3.

Example 6: Margins with continuous variables

To the above example, we will add the continuous covariate age to the model and then rerun margins sex group.

```
. logistic outcome i.sex i.group sex#group age
  (output omitted)
. margins sex group
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1600644	.0125653	12.74	0.000	.1354368	.184692
1	.1966902	.0100043	19.66	0.000	.1770821	.2162983
group						
1	.2251302	.0123233	18.27	0.000	.200977	.2492834
2	.150603	.0116505	12.93	0.000	.1277685	.1734376
3	.0736157	.0337256	2.18	0.029	.0075147	.1397167

Compared with the results presented in example 5, results for sex change little, but results for groups 1 and 3 change markedly. The tables differ because now we are adjusting for the continuous covariate age, as well as for sex and group.

We will continue examining interactions in example 8. Because we have added a continuous variable, let's take a detour to explain how to obtain margins for continuous variables and to explain their interpretation.

Example 7: Margins of continuous variables

Continuing with our example of

```
. logistic outcome i.sex i.group sex#group age
```

let's examine the continuous covariate age.

You are not allowed to type margins age; doing that will produce an error:

```
. margins age
'age' not found in list of covariates
r(322);
```

The message "'age' not found in list of covariates" is margins' way of saying, "Yes, age might be in the model, but if it is, it is not included as a factor variable; it is in as a continuous variable." Sometimes, Stata is overly terse. margins might also say that because age is continuous there are an infinite number of values at which it could evaluate the margins. At what value(s) should age be fixed? margins requires more guidance with continuous covariates. We can provide that guidance by using the at() option and typing

```
. margins, at(age=40)
```

To understand why that yields the desired result, let us tell you that if you were to type

```
. margins
```

`margins` would report the overall margin—the margin that holds nothing constant. Because our model is logistic, the average value of the predicted probabilities would be reported. The `at()` option fixes one or more covariates to the value(s) specified and can be used with both factor and continuous variables. Thus, if you typed `margins, at(age=40)`, then `margins` would average over the data the responses for everybody, setting `age=40`. Here is what happens when you type that:

```
. margins, at(age=40)
Predictive margins                                Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
at           : age             =          40
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_cons	.1133603	.0070731	16.03	0.000	.0994972	.1272234

Reported is the margin for `age` $= 40$, adjusted for the other covariates in our model.

If we wanted to obtain the margins for age 30, 35, 40, 45, and 50, we could type

```
. margins, at(age=(30 35 40 45 50))
```

or, equivalently,

```
. margins, at(age=(30(5)50))
```

Example 8: Margins of interactions

Our model is

```
. logistic outcome i.sex i.group sex#group age
```

We can obtain the margins of all possible combinations of the levels of `sex` and the levels of `group` by typing

```
. margins sex#group
Predictive margins                                Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex#group						
0 1	.2379605	.0237178	10.03	0.000	.1914745	.2844465
0 2	.0658294	.0105278	6.25	0.000	.0451953	.0864636
0 3	.0538001	.0136561	3.94	0.000	.0270347	.0805656
1 1	.2158632	.0112968	19.11	0.000	.1937218	.2380045
1 2	.2054406	.0183486	11.20	0.000	.1694781	.2414032
1 3	.085448	.0533914	1.60	0.110	-.0191973	.1900932

The first line in the table reports the marginal probability for sex = 0 and group = 1. That is, it reports the estimated probability if everyone in the data were treated as if they were sex = 0 and group = 1.

Also reported are all the other combinations of sex and group.

By the way, we could have typed margins sex#group even if our fitted model did not include sex#group. Estimation is one thing, and asking questions about the nature of the estimates is another. margins does, however, require that i.sex and i.group appear somewhere in the model, because fixing a value outside the model would just produce the grand margin, and you can separately ask for that if you want it by typing margins without arguments.

Example 9: Decomposing margins

We have the model

```
. logistic outcome i.sex i.group sex#group age
```

In example 6, we typed margins sex and obtained 0.160 for males and 0.197 for females. We are going to decompose each of those numbers. Let us explain:

1. The margin for males, 0.160, treats everyone as if they were male, and that amounts to simultaneously
    1a. treating males as males and
    1b. treating females as males.
2. The margin for females, 0.197, treats everyone as if they were female, and that amounts to simultaneously
    2a. treating males as females and
    2b. treating females as females.

The margins 1a and 1b are the decomposition of 1, and the margins 2a and 2b are the decomposition of 2.

We could obtain 1a and 2a by typing

```
. margins if sex==0, at(sex=(0 1))
```

because the qualifier if sex==0 would restrict margins to running on only the males. Similarly, we could obtain 1b and 2b by typing

```
. margins if sex==1, at(sex=(0 1))
```

We run these examples below:

```
. margins if sex==0, at(sex=(0 1))
Predictive margins                                Number of obs   =       1498
Model VCE    : OIM
Expression   : Pr(outcome), predict()
1._at        : sex             =           0
2._at        : sex             =           1
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_at						
1	.0794393	.0062147	12.78	0.000	.0672586	.0916199
2	.1335584	.0127351	10.49	0.000	.1085981	.1585187

```
. margins if sex==1, at(sex=(0 1))
Predictive margins                                Number of obs   =       1502
Model VCE    : OIM
Expression   : Pr(outcome), predict()
1._at        : sex             =           0
2._at        : sex             =           1
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_at						
1	.2404749	.0199709	12.04	0.000	.2013326	.2796171
2	.2596538	.0104756	24.79	0.000	.2391219	.2801857

Putting together the results from example 6 and the results above, we have

Margin treating everybody as themself	0.170
Margin treating everybody as male	0.160
Margin treating male as male	0.079
Margin treating female as male	0.240
Margin treating everybody as female	0.197
Margin treating male as female	0.134
Margin treating female as female	0.260

Example 10: Testing margins—contrasts of margins

Continuing with the previous example, it would be interesting to test the equality of 2b and 1b, to test whether the average probability of a positive outcome for females treated as females is equal to that for females treated as males. That test would be different from testing the overall significance of `sex` in our model. The test performed on our model would be a test of whether the probability of a positive outcome differs between males and females when they have equal values of the other covariates. The test of equality of margins is a test of whether the *average* probabilities differ given the different pattern of values of the other covariates that the two sexes have in our data.

We can also perform such tests by treating the results from `margins` as estimation results. There are three steps required to perform tests on margins. First, you must arrange it so that all the margins of interest are reported by just one `margins` command. Second, you must specify `margins`' `post` option. Third, you perform the test with the `test` command.

Such tests and comparisons can be readily performed by contrasting margins; see [R] **margins, contrast**. Also see *Contrasts of margins—effects (discrete marginal effects)* in [R] **marginsplot**.

In the previous example, we used two commands to obtain our results, namely,

```
. margins if sex==0, at(sex=(0 1))
. margins if sex==1, at(sex=(0 1))
```

We could, however, have obtained the same results by typing just one command:

```
. margins, over(sex) at(sex=(0 1))
```

Performing `margins, over(sex)` first restricts the sample to `sex==0` and then restricts it to `sex==1`, and that is equivalent to the two different `if` conditions that we specified before.

To test whether females treated as females is equal to females treated as males, we will need to type

```
. margins, over(sex) at(sex=(0 1)) post
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We admit that the second command may seem to have come out of nowhere. When we specify `post` on the `margins` command, `margins` behaves as if it were an estimation command, which means that 1) it posts its estimates and full VCE to `e()`, 2) it gains the ability to replay results just as any estimation command can, and 3) it gains access to the standard postestimation commands. Item 3 explains why we could use `test`. We learned that we wanted to test `_b[2._at#1.sex]` and `_b[1._at#1.sex]` by replaying the estimation results, but this time with the standard estimation command `coeflegend` option. So what we typed was

```
. margins, over(sex) at(sex=(0 1)) post
. margins, coeflegend
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We will let you try `margins, coeflegend` for yourself. The results of running the other two commands are

```
. margins, over(sex) at(sex=(0 1)) post
Predictive margins                                 Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : sex
1._at        : 0.sex
                    sex              =           0
               1.sex
                    sex              =           0
2._at        : 0.sex
                    sex              =           1
               1.sex
                    sex              =           1
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_at#sex						
1 0	.0794393	.0062147	12.78	0.000	.0672586	.0916199
1 1	.2404749	.0199709	12.04	0.000	.2013326	.2796171
2 0	.1335584	.0127351	10.49	0.000	.1085981	.1585187
2 1	.2596538	.0104756	24.79	0.000	.2391219	.2801857

```
. test _b[2._at#1.sex] = _b[1._at#1.sex]
 ( 1)  - 1bn._at#1.sex + 2._at#1.sex = 0
           chi2(  1) =    0.72
         Prob > chi2 =    0.3951
```

We can perform the same test in one command using contrasts of margins:

```
. logistic outcome i.sex i.group sex#group age
  (output omitted)
. margins, over(sex) at(sex=(0 1)) contrast(atcontrast(r._at) wald)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : sex
1._at        : 0.sex
                    sex             =           0
               1.sex
                    sex             =           0
2._at        : 0.sex
                    sex             =           1
               1.sex
                    sex             =           1
```

	df	chi2	P>chi2
_at@sex			
(2 vs 1) 0	1	14.59	0.0001
(2 vs 1) 1	1	0.72	0.3951
Joint	2	16.13	0.0003

	Delta-method			
	Contrast	Std. Err.	[95% Conf.	Interval]
_at@sex				
(2 vs 1) 0	.0541192	.0141706	.0263453	.081893
(2 vs 1) 1	.0191789	.0225516	-.0250215	.0633793

We refitted our logistic model because its estimation results were replaced when we posted our margins. The syntax to perform the contrast we want is admittedly not obvious. Contrasting (testing) across `at()` groups is more difficult than contrasting across the margins themselves or across `over()` groups, because we have no natural place for the contrast operators (`r.`, in our case). We also explicitly requested Wald tests of the contrasts, which are not provided by default. Nevertheless, the chi-squared statistic and its p-value for `(2 vs 1)` for `sex` $= 1$ matches the results of our `test` command. We also obtain the test of whether the response of males treated as males is equal to the response of males treated as females.

For a gentler introduction to contrasts of margins, see [R] **margins, contrast**.

Example 11: Margins of a specified prediction

We will fit the model

```
. use http://www.stata-press.com/data/r12/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we will tell the following story about the variables: We run a peach orchard where we allow people to pick their own peaches. A person receives one empty basket in exchange for $20, along with the right to enter the orchard. There is no official limit on how many peaches a person can pick, but only 90 peaches will fit into a basket. The dependent variable in the above tobit model, `ycn`, is the number of peaches picked. We use tobit, a special case of censored-normal regression, because `ycn` is censored at 90.

After fitting this model, if we typed

```
. margins sex
```

we would obtain the margins for males and for females of the uncensored number of peaches picked. We would obtain that because `predict` after `tobit` produces the uncensored number by default. To obtain the censored prediction, we would have to specify `predict`'s `ystar(.,90)` option. If we want the margins based on that response, we type

```
. margins sex, predict(ystar(.,90))
```

The results of typing that are

```
. tobit ycn i.sex i.group sex#group age, ul(90)
  (output omitted)
. margins sex, predict(ystar(.,90))
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : E(ycn*|ycn<90), predict(ystar(.,90))
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	62.21804	.5996928	103.75	0.000	61.04266	63.39342
1	78.34272	.455526	171.98	0.000	77.4499	79.23553

In our previous examples, `sex` = 1 has designated females, so evidently the females visiting our orchard are better at filling baskets than the men.

Example 12: Margins of a specified expression

Continuing with our peach orchard example and the previously fit model

```
. use http://www.stata-press.com/data/r12/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

let's examine how well our baskets are working for us. What is the proportion of the number of peaches actually picked to the number that would have been picked were the baskets larger? As mentioned in example 11, `predict, ystar(.,90)` produces the expected number picked given the limit of basket size. `predict, xb` would predict the expected number without a limit. We want the ratio of those two predictions. That ratio will measure as a proportion how well the baskets work. Thus we could type

```
. margins sex, expression(predict(ystar(.,90))/predict(xb))
```

That would give us the proportion for everyone treated as male and everyone treated as female, but what we want to know is how well baskets work for true males and true females, so we will type

```
. margins, over(sex) expression(predict(ystar(.,90))/predict(xb))
```

```
. margins, over(sex) expression(predict(ystar(0,90))/predict(xb))
Predictive margins                                Number of obs   =       3000
Model VCE    : OIM
Expression   : predict(ystar(0,90))/predict(xb)
over         : sex
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.9811785	.0013037	752.60	0.000	.9786233	.9837337
1	.9419962	.0026175	359.88	0.000	.936866	.9471265

By the way, we could count the number of peaches saved by the limited basket size during the period of data collection by typing

```
. count
  3000
. margins, expression(3000*(predict(xb)-predict(ystar(.,90))))
  (output omitted)
```

The number of peaches saved turns outs to be 9,183.

Example 13: Margins with multiple outcomes (responses)

Estimation commands such as `mlogit` and `mprobit` (see [R] **mlogit** and [R] **mprobit**) calculate multiple responses, and those multiple responses are reflected in the options available with `predict` after estimation. Obtaining margins for such estimators is thus the same as obtaining margins of a specified prediction, which was demonstrated in example 11. The solution is to include the *predict_opt* that selects the desired response in `margins`' `predict(`*predict_opt*`)` option.

If we fit the multinomial logistic model

```
. mlogit group i.sex age
```

then to obtain the margins for the probability that `group` = 1, we would type

```
. margins sex, predict(outcome(1))
```

and to obtain the margins for the probability that `group` = 3, we would type

```
. margins sex, predict(outcome(3))
```

We learned about the `outcome(1)` and `outcome(3)` options by looking in [R] **mlogit postestimation**. For an example using `margins` with a multiple-outcome estimator, see example 4 in [R] **mlogit postestimation**.

Example 14: Margins with multiple equations

Estimation commands such as `mvreg`, `manova`, `sureg`, and `reg3` (see [R] **mvreg**, [MV] **manova**, [R] **sureg**, and [R] **reg3**) fit multiple equations. Obtaining margins for such estimators is the same as obtaining margins with multiple outcomes (see example 13), which in turn is the same as obtaining margins of a specified prediction (see example 11). You place the relevant option from the estimator's `predict` command into `margins`' `predict(`*predict_opt*`)` option.

If we fit the seemingly unrelated regression model

```
. sureg (y = i.sex age) (distance = i.sex i.group)
```

we can obtain the marginal means of y for males and females by typing

```
. margins sex, predict(equation(y))
```

and we can obtain the marginal means of distance by typing

```
. margins sex, predict(equation(distance))
```

We could obtain the difference between the margins of y and distance by typing

```
. margins sex, expression(predict(equation(y)) -
> predict(equation(distance)))
```

More examples can be found in [MV] **manova** and [MV] **manova postestimation**.

Example 15: Margins evaluated out of sample

You can fit your model on one dataset and use margins on another if you specify margins' noesample option. Remember that margins reports estimated average responses, and, unless you lock all the covariates at fixed values by using the at() option, the remaining variables are allowed to vary as they are observed to vary in the data. That is indeed the point of using margins. The fitted model provides the basis for adjusting for the remaining variables, and the data provide their values. The predictions produced by margins are of interest assuming the data used by margins are in some sense interesting or representative. In some cases, you might need to fit your model on one set of data and perform margins on another.

In example 11, we fit the model

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we told a story about our peach orchard in which we charged people $20 to collect a basket of peaches, where baskets could hold at most 90 peaches. Let us now tell you that we believe the data on which we estimated those margins were unrepresentative, or at least, we have a more representative sample stored in another .dta file. That dataset includes the demographics of our customers but does not include counts of peaches picked. It is a lot of work counting those peaches.

Thus we will fit our model just as we did previously using the detailed data, but we will bring the other, more representative dataset into memory before issuing the margins sex, predict(ystar(.,90)) command, and we will add noesample to it.

```
. use http://www.stata-press.com/data/r12/margex
(Artificial data for margins)
. tobit ycn i.sex i.group sex#group age, ul(90)
  (output omitted)
. use http://www.stata-press.com/data/r12/peach
. margins sex, predict(ystar(.,90)) noesample
Predictive margins                              Number of obs   =       2727
Model VCE    : OIM
Expression   : E(ycn*|ycn<90), predict(ystar(.,90))
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	56.79774	1.003727	56.59	0.000	54.83047	58.76501
1	75.02146	.643742	116.54	0.000	73.75975	76.28317

In example 12, we produced an estimate of the number of peaches saved by the limited-size baskets. We can update that estimate using the new demographic data by typing

```
. count
  2727
. margins, exp(2727*(predict(xb)-predict(ystar(.,90)))) noesample
  (output omitted)
```

By running the above, we find that the updated number of peaches saved is 6,408.

Obtaining margins of derivatives of responses (a.k.a. marginal effects)

Derivatives of responses are themselves responses, so everything said above in *Obtaining margins of responses* is equally true of derivatives of responses, and every example above could be repeated here substituting the derivative of the response for the response.

Derivatives are of interest because they are an informative way of summarizing fitted results. The change in a response for a change in the covariate is easy to understand and to explain. In simple models, one hardly needs `margins` to assist in obtaining such margins. Consider the simple linear regression

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \epsilon$$

The derivatives of the responses are

$$dy/d(\text{sex}) = \beta_1$$
$$dy/d(\text{age}) = \beta_2$$

The derivatives are the fitted coefficients. How does y change between males and females? It changes by β_1. How does y change with age? It changes by β_2 per year.

If you make the model a little more complicated, however, the need for margins arises. Consider the model

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \epsilon$$

Now the derivative with respect to age is

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age}$$

The change in y for a change in age itself changes with age, and so to better understand the fitted results, you might want to make a table of the change in y for a change in age for age $= 30$, age $= 40$, and age $= 50$. `margins` can do that.

Consider an even more complicated model, such as

$$\begin{aligned} y = {} & \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} \\ & + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \end{aligned} \tag{1}$$

The derivatives are

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp}$$

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age}$$
$$dy/d(\text{bp}) = \beta_4 + \beta_5 \times \text{sex}$$

$$dy/d(\text{tmt}) = \beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$$

At this point, `margins` becomes indispensable.

Do not specify marginlist when you mean over()

`margins` has the same syntax when used with derivatives of responses as when used with responses. To obtain derivatives, one specifies the `dydx()` option. If we wanted to examine the response variable $dy/d(\text{tmt})$, we would specify `margins`' `dydx(tmt)` option. The rest of the `margins` command has the same syntax as ordinarily, although one tends to specify different syntactical elements. For instance, one usually does not specify a *marginlist*. If we typed

```
. margins sex, dydx(tmt)
```

we would obtain $dy/d(\text{tmt})$ calculated first as if everyone were male and then as if everyone were female. At the least, we would probably want to specify

```
. margins sex, dydx(tmt) grand
```

so as also to obtain $dy/d(\text{tmt})$, the overall margin, the margin with everyone having their own value of sex. Usually, however, all we want is the overall margin, and because `grand` is the default when the *marginlist* is not specified, we would just type

```
. margins, dydx(tmt)
```

Alternatively, if we were interested in the decomposition by sex, then rather than type `margins sex, dydx(tmt)`, we probably want to type

```
. margins, over(sex) dydx(tmt)
```

This command gives us the average effect of tmt for males and again for females rather than the average effect with everyone treated as male and then again with everyone treated as female.

Use at() freely, especially with continuous variables

Another option one tends to use more often with derivatives of responses than one does with responses is `at()`. Such use is often to better understand or to communicate how the response varies, or, in technical jargon, to explore the nature of the response surface.

For instance, the effect $dy/d(\text{tmt})$ in (1) is equal to $\beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$, and so simply to understand how treatment varies with age, we may want to fix age at various values. We might type

```
. margins, dydx(tmt) over(sex) at(age=(30 40 50))
```

Expressing derivatives as elasticities

You specify the `dydx(`*varname*`)` option on the `margins` command to use $dy/d(\textit{varname})$ as the response variable. If you want that derivative expressed as an elasticity, you can specify `eyex(`*varname*`)`, `eydx(`*varname*`)`, or `dyex(`*varname*`)`. You substitute `e` for `d` where you want an elasticity. The formulas are

$$\begin{aligned}
\texttt{dydx()} &= dy/dx \\
\texttt{eyex()} &= dy/dx \times (x/y) \\
\texttt{eydx()} &= dy/dx \times (1/y) \\
\texttt{dyex()} &= dy/dx \times (x)
\end{aligned}$$

and the interpretations are

`dydx()`:		change in y for a		change in x
`eyex()`:	proportional	change in y for a	proportional	change in x
`eydx()`:	proportional	change in y for a		change in x
`dyex()`:		change in y for a	proportional	change in x

As `margins` always does with response functions, calculations are made at the observational level and are then averaged. Let's assume that in observation 5, $dy/dx = 0.5$, $y = 15$, and $x = 30$; then

$$\texttt{dydx()} = 0.5$$
$$\texttt{eyex()} = 1.0$$
$$\texttt{eydx()} = 0.03$$
$$\texttt{dyex()} = 15.0$$

Many social scientists would informally explain the meaning of `eyex()` $= 1$ as "y increases 100% when x increases 100%" or as "y doubles when x doubles", although neither statement is literally true. `eyex()`, `eydx()`, and `dyex()` are rates evaluated at a point, just as `dydx()` is a rate, and all such interpretations are valid only for small (infinitesimal) changes in x. It is true that `eyex()` $= 1$ means y increases with x at a rate such that, if the rate were constant, y would double if x doubled. This issue of casual interpretation is no different from casually interpreting `dydx()` as if it represents the response to a unit change. It is not necessarily true that `dydx()` $= 0.5$ means that "y increases by 0.5 if x increases by 1". It is true that "y increases with x at a rate such that, if the rate were constant, y would increase by 0.5 if x increased by 1".

`dydx()`, `eyex()`, `eydx()`, and `dyex()` may be used with continuous x variables. `dydx()` and `eydx()` may also be used with factor variables.

Derivatives versus discrete differences

In (1),

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon$$

Let us call your attention to the derivatives of y with respect to age and sex:

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \tag{2}$$

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp} \tag{3}$$

`age` is presumably a continuous variable and (2) is precisely how `margins` calculates its derivatives when you type `margins, dydx(age)`. `sex`, however, is presumably a factor variable, and `margins` does not necessarily make the calculation using (3) were you to type `margins, dydx(sex)`. We will explain, but let us first clarify what we mean by a continuous and a factor variable. Say that you fit (1) by typing

```
. regress y i.sex age c.age#c.age i.bp bp#sex
> i.tmt tmt#c.age tmt#c.age#c.age
```

It is important that sex entered the model as a factor variable. It would not do to type regress y sex ... because then sex would be a continuous variable, or at least it would be a continuous variable from Stata's point of view. The model estimates would be the same, but margins' understanding of those estimates would be a little different. With the model estimated using i.sex, margins understands that either sex is 0 or sex is 1. With the model estimated using sex, margins thinks sex is continuous and, for instance, sex = 1.5 is a possibility.

margins calculates dydx() differently for continuous and for factor variables. For continuous variables, margins calculates dy/dx. For factor variables, margins calculates the discrete first-difference from the base category. To obtain that for sex, write down the model and then subtract from it the model evaluated at the base category for sex, which is sex = 0. If you do that, you will get the same formula as we obtained for the derivative, namely,

$$\text{discrete difference}\{(\text{sex}=1)-(\text{sex}=0)\} = \beta_1 + \beta_5 \times \text{bp}$$

We obtain the same formula because our model is linear regression. Outside of linear regression, and outside of linear response functions generally, the discrete difference is not equal to the derivative. The discrete difference is not equal to the derivative for logistic regression, probit, etc. The discrete difference calculation is generally viewed as better for factor variables than the derivative calculation because the discrete difference is what would actually be observed.

If you want the derivative calculation for your factor variables, specify the continuous option on the margins command.

Example 16: Average marginal effect (partial effects)

Concerning the title of this example, the way we use the term marginal effect, the effects of factor variables are calculated using discrete first-differences. If you wanted the continuous calculation, you would specify margins' continuous option in what follows.

```
. use http://www.stata-press.com/data/r12/margex
(Artificial data for margins)
. logistic outcome treatment##group age c.age#c.age treatment#c.age
  (output omitted)
. margins, dydx(treatment)
Average marginal effects                        Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment
```

	dy/dx	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
1.treatment	.0385625	.0162848	2.37	0.018	.0066449	.0704801

```
Note: dy/dx for factor levels is the discrete change from the base level.
```

The average marginal effect of treatment on the probability of a positive outcome is 0.039.

Example 17: Average marginal effect of all covariates

We will continue with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

if we wanted the average marginal effects for all covariates, we would type `margins, dydx(*)` or `margins, dydx(_all)`; they mean the same thing. This is probably the most common way `margins, dydx()` is used.

```
. margins, dydx(*)
Average marginal effects                        Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.group age
```

	dy/dx	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
1.treatment	.0385625	.0162848	2.37	0.018	.0066449	.0704801
group						
2	-.0776906	.0181584	-4.28	0.000	-.1132805	-.0421007
3	-.1505652	.0400882	-3.76	0.000	-.2291366	-.0719937
age	.0095868	.0007796	12.30	0.000	.0080589	.0111148

```
Note: dy/dx for factor levels is the discrete change from the base level.
```

Example 18: Evaluating marginal effects over the response surface

Continuing with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

What follows maps out the entire response surface of our fitted model. We report the marginal effect of treatment evaluated at `age` $= 20, 30, \ldots, 60$, by each level of group.

```
. margins group, dydx(treatment) at(age=(20(10)60))
Conditional marginal effects                      Number of obs   =       3000
Model VCE    : OIM

Expression   : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment

1._at        : age             =          20

2._at        : age             =          30

3._at        : age             =          40

4._at        : age             =          50

5._at        : age             =          60
```

	dy/dx	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
1.treatment						
_at#group						
1 1	-.0208409	.0152862	-1.36	0.173	-.0508013	.0091196

5 3	.1688268	.1642191	1.03	0.304	-.1530368	.4906904

Note: dy/dx for factor levels is the discrete change from the base level.

Obtaining margins with survey data and representative samples

The standard errors and confidence intervals produced by `margins` are based by default on the delta method applied to the VCE of the current estimates. Delta-method standard errors treat the covariates at which the response is evaluated as given or fixed. Such standard errors are appropriate if you specify `at()` to fix the covariates, and they are appropriate when you are making inferences about groups exactly like your sample whether you specify `at()` or not.

On the other hand, if you have a representative sample of the population or if you have complex survey data and if you want to make inferences about the underlying population, you need to account for the variation in the covariates that would arise in repeated sampling. You do that using `vce(unconditional)`, which invokes a different standard-error calculation based on Korn and Graubard (1999). Syntactically, there are three cases. They all involve specifying the `vce(unconditional)` option on the `margins` command:

1. *You have a representative random sample, and you have not* `svyset` *your data.*
   When you fit the model, you need to specify the `vce(robust)` or `vce(cluster` *clustvar*`)` option. When you issue the `margins` command, you need to specify the `vce(unconditional)` option.

2. *You have a weighted sample, and you have not* `svyset` *your data.*
   You need to specify `[pw=weight]` when you fit the model and, of course, specify the `vce(unconditional)` option on the `margins` command. You do not need to specify the weights on the `margins` command because `margins` will obtain them from the estimation results.

3. *You have* `svyset` *your data, whether it be a simple random sample or something more complex including weights, strata, sampling units, or poststratification.*
   You need to use the `svy` prefix when you fit the model. You need to specify `vce(unconditional)` when you issue the `margins` command. You do not need to respecify the weights.

   Even though the data are `svyset`, and even though the estimation was `svy` estimation, `margins` does not default to `vce(unconditional)`. It does not default to `vce(unconditional)` because there are valid reasons to want the data-specific, `vce(delta)` standard-error estimates. Whether you specify `vce(unconditional)` or not, `margins` uses the weights, so you do not need to respecify them even if you are using `vce(unconditional)`.

`vce(unconditional)` is allowed only after estimation with `vce(robust)`, `vce(cluster ...)`, or the `svy` prefix. If the VCE of the current estimates was specified as clustered, so will be the VCE estimates of `margins`. If the estimates were from a survey estimation, the survey settings in the dataset will be used by `margins`.

When you use `vce(unconditional)`, never specify `if` *exp* or `in` *range* on the `margins` command; instead, specify the `subpop(if` *exp*`)` option. You do that for the usual reasons; see [SVY] **subpopulation estimation**. If you specify `over(`*varlist*`)` to examine subgroups, the subgroups will automatically be treated as subpopulations.

Example 19: Inferences for populations, margins of response

In example 6, we fit the model

```
. logistic outcome i.sex i.group sex#group age
```

and we obtained margins by sex and margins by group,

```
. margins sex group
```

If our data were randomly drawn from the population of interest and we wanted to account for this, we would have typed

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
. margins sex group, vce(unconditional)
```

We do that below:

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
  (output omitted)
. margins sex group, vce(unconditional)
Predictive margins                                Number of obs   =       3000
Expression   : Pr(outcome), predict()
```

	Unconditional Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1600644	.0131685	12.16	0.000	.1342546	.1858743
1	.1966902	.0104563	18.81	0.000	.1761963	.2171841
group						
1	.2251302	.0127069	17.72	0.000	.200225	.2500354
2	.150603	.0118399	12.72	0.000	.1273972	.1738088
3	.0736157	.0343188	2.15	0.032	.0063522	.1408793

The estimated margins are the same as they were in example 6, but the standard errors and confidence intervals differ, although not by much. Given that we have 3,000 observations in our randomly drawn sample, we should expect this.

Example 20: Inferences for populations, marginal effects

In example 17, we fit a logistic model and then obtained the average marginal effects for all covariates by typing

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
. margins, dydx(*)
```

To repeat that and also obtain standard errors for our population, we would type

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age,
> vce(robust)
. margins, dydx(*) vce(unconditional)
```

The results are

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age, vce(robust)
  (output omitted)
. margins, dydx(*) vce(unconditional)
Average marginal effects                          Number of obs   =       3000
Expression   : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.group age
```

	Unconditional dy/dx	Std. Err.	z	P>|z|	[95% Conf.	Interval]
1.treatment	.0385625	.0163872	2.35	0.019	.0064442	.0706808
group						
2	-.0776906	.0179573	-4.33	0.000	-.1128863	-.0424949
3	-.1505652	.0411842	-3.66	0.000	-.2312848	-.0698456
age	.0095868	.0007814	12.27	0.000	.0080553	.0111183

```
Note: dy/dx for factor levels is the discrete change from the base level.
```

Example 21: Inferences for populations with svyset data

See example 3 in [SVY] **svy postestimation**.

Standardizing margins

A standardized margin is the margin calculated on data different from the data used to fit the model. Typically, the word standardized is reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

Say that you work for a hospital and have fit a model of mortality on the demographic characteristics of the hospital's patients. At this stage, were you to type

```
. margins
```

you would obtain the mortality rate for your hospital. You have another dataset, `hstandard.dta`, that contains demographic characteristics of patients across all hospitals along with the population of each hospital recorded in the `pop` variable. You could obtain the expected mortality rate at your hospital if your patients matched the characteristics of the standard population by typing

```
. use http://www.stata-press.com/data/r12/hstandard, clear
. margins [fw=pop], noesample
```

You specified `noesample` because the margin is being calculated on data other than the data used to estimate the model. You specified `[fw=pop]` because the reference dataset you are using included population counts, as many reference datasets do.

Obtaining margins as though the data were balanced

Here we discuss what are commonly called estimated marginal means or least-squares means. These are margins assuming that all levels of factor variables are equally likely or, equivalently, that the design is balanced. The seminal reference on these margins is Searle, Speed, and Milliken (1980).

In designed experiments, observations are often allocated in a balanced way so that the variances can be easily compared and decomposed. At the Acme Portable Widget Company, they are experimenting with a new machine. The machine has three temperature settings and two pressure settings; a combination of settings will be optimal on any particular day, determined by the weather. At start-up, one runs a quick test and chooses the optimal setting for the day. Across different days, each setting will be used about equally, says the manufacturer.

In experiments with the machine, 10 widgets were collected for stress testing at each of the settings over a six-week period. We wish to know the average stress-test value that can be expected from these machines over a long period.

Balancing using asbalanced

The data were intended to be balanced, but unfortunately, the stress test sometimes destroys samples before the stress can be measured. Thus even though the experiment was designed to be balanced, the data are not balanced. You specify the `asbalanced` option to estimate the margins as if the data were balanced. We will type

```
. use http://www.stata-press.com/data/r12/acmemanuf
. regress y pressure##temp
. margins, asbalanced
```

So that you can compare the asbalanced results with the observed results, we will also include margins without the asbalanced option in what follows:

```
. use http://www.stata-press.com/data/r12/acmemanuf
. regress y pressure##temp
  (output omitted)
. margins
Predictive margins                              Number of obs   =         49
Model VCE    : OLS
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_cons	109.9214	1.422629	77.27	0.000	107.1331	112.7097

```
. margins, asbalanced
Adjusted predictions                            Number of obs   =         49
Model VCE    : OLS
Expression   : Linear prediction, predict()
at           : pressure         (asbalanced)
               temp             (asbalanced)
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_cons	115.3758	1.530199	75.40	0.000	112.3767	118.375

❑ Technical note

Concerning how asbalanced calculations are performed, if a factor variable has l levels, then each level's coefficient contributes to the response weighted by $1/l$. If two factors, a and b, interact, then each coefficient associated with their interaction is weighted by $1/(l_a \times l_b)$.

If a balanced factor interacts with a continuous variable, then each coefficient in the interaction is applied to the value of the continuous variable, and the results are weighted equally. So, if the factor being interacted has l_a levels, the effect of each coefficient on the value of the continuous covariate is weighted by $1/l_a$.

❑

Balancing by standardization

To better understand the balanced results, we can perform the balancing ourselves by using the standardizing method shown in *Standardizing margins*. To do that, we will input a balanced dataset and then type margins, noesample.

```
. use http://www.stata-press.com/data/r12/acmemanuf
. regress y pressure##temp
  (output omitted)
. drop _all
. input pressure temp
     pressure       temp
  1. 1 1
  2. 1 2
  3. 1 3
  4. 2 1
  5. 2 2
  6. 2 3
  7. end
. margins, noesample
Predictive margins                                Number of obs   =          6
Model VCE    : OLS
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
_cons	115.3758	1.530199	75.40	0.000	112.3767	118.375

We obtain the same results as previously.

Balancing nonlinear responses

If our testing had produced a binary outcome, say, acceptable/unacceptable, rather than a continuous variable, we would type

```
. use http://www.stata-press.com/data/r12/acmemanuf, clear
. logistic acceptable pressure##temp
. margins, asbalanced
```

The result of doing that would be 0.680. If we omitted the `asbalanced` option, the result would have been 0.667. The two results are so similar because `acmemanuf.dta` is nearly balanced.

Even though the `asbalanced` option can be used on both linear and nonlinear responses, such as probabilities, there is an issue of which you should be aware. The most widely used formulas for balancing responses apply the balancing to the linear prediction, average that as if it were balanced, and then apply the nonlinear transform. That is the calculation that produced 0.680.

An alternative would be to apply the standardization method. That amounts to making the linear predictions observation by observation, applying the nonlinear transform to each, and then averaging the nonlinear result as if it were balanced. You could do that by typing

```
. use http://www.stata-press.com/data/r12/acmemanuf, clear
. logistic acceptable pressure##temp
. clear
. input pressure temp
  (see above for entered data)
. margins, noesample
```

The result from the standardization procedure would be 0.672. These two ways of averaging nonlinear responses are discussed in detail in Lane and Nelder (1982) within the context of general linear models.

Concerning the method used by the `asbalanced` option, if your data start balanced and you have a nonlinear response, you will get different results with and without the `asbalanced` option!

Treating a subset of covariates as balanced

So far, we have treated all the covariates as if they were balanced. `margins` will allow you to treat a subset of the covariates as balanced, too. For instance, you might be performing an experiment in which you are randomly allocating patients to a treatment arm and so want to balance on arm, but you do not want to balance the other characteristics because you want mean effects for the experiment's population.

In this example, we will imagine that the outcome of the experiment is continuous. We type

```
. use http://www.stata-press.com/data/r12/margex, clear
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm)
```

If we wanted results balanced on `agegroup` as well, we could type

```
. margins, at((asbalanced) arm agegroup)
```

If we wanted results balanced on all three covariates, we could type

```
. margins, at((asbalanced) arm agegroup sex)
```

or we could type

```
. margins, at((asbalanced) _factor)
```

or we could type

```
. margins, asbalanced
```

Using fvset design

As a convenience feature, equivalent to

```
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm sex)
```

is

```
. fvset design asbalanced arm sex
. regress y arm##sex sex##agegroup
. margins
```

The advantage of the latter is that you have to set the variables as balanced only once. This is useful when balancing is a design characteristic of certain variables and you wish to avoid accidentally treating them as unbalanced.

If you `save` your data after `fvset`ting, the settings will be remembered in future sessions. If you want to clear the setting(s), type

```
. fvset clear varlist
```

See [R] **fvset**.

Balancing in the presence of empty cells

The issue of empty cells is not exclusively an issue of balancing, but there are special considerations when balancing. Empty cells are discussed generally in *Estimability of margins*.

An empty cell is an interaction of levels of two or more factor variables for which you have no data. Usually, margins involving empty cells cannot be estimated. When balancing, there is an alternate definition of the margin that allows the margin to be estimated. `margins` makes the alternate calculation when you specify the `emptycells(reweight)` option. By default, `margins` uses the `emptycells(strict)` option.

If you have empty cells in your data and you request margins involving the empty cells, those margins will be marked as not estimable even if you specify the `asbalanced` option.

```
. use http://www.stata-press.com/data/r12/estimability, clear
(margins estimability)
. regress y sex##group
  (output omitted)
. margins sex, asbalanced
Adjusted predictions                              Number of obs   =         69
Model VCE    : OLS
Expression   : Linear prediction, predict()
Empty cells  : reweight
at           : sex             (asbalanced)
               group           (asbalanced)
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	21.91389	1.119295	19.58	0.000	19.72011	24.10767
1	.	(not estimable)				

This example is discussed in *Estimability of margins*, although without the `asbalanced` option. What is said there is equally relevant to the `asbalanced` case. For reasons explained there, the margin for `sex` = 1 cannot be estimated.

The margin for `sex` = 1 can be estimated in the `asbalanced` case if you are willing to make an assumption. Remember that `margins` makes the balanced calculation by summing the responses associated with the levels and then dividing by the number of levels. If you specify `emptycells(reweight)`, `margins` sums what is available and divides by the number available. Thus you are assuming that, whatever the responses in the empty cells, those responses are such that they would not change the overall mean of what is observed.

The results of specifying `emptycells(reweight)` are

```
. margins sex, asbalanced emptycells(reweight)
Adjusted predictions                              Number of obs   =         69
Model VCE    : OLS
Expression   : Linear prediction, predict()
Empty cells  : reweight
at           : sex             (asbalanced)
               group           (asbalanced)
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	21.91389	1.119295	19.58	0.000	19.72011	24.10767
1	24.85185	1.232304	20.17	0.000	22.43658	27.26712

Obtaining margins with nested designs

Introduction

Factors whose meaning depends on other factors are called nested factors, and the factors on which their meaning depends are called the nesting factors. For instance, assume that we have a sample of patients and each patient is assigned to one doctor. Then patient is nested within doctor. Let the identifiers of the first 5 observations of our data be

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	1	Karen
2	2	Hank

The first patient on one doctor's list has nothing whatsoever to do with the first patient on another doctor's list. The meaning of `patient` = 1 is defined only when the value of `doctor` is supplied.

Nested factors enter into models as interactions of nesting and nested; the nested factor does not appear by itself. We might estimate a model such as

```
. regress y ... i.doctor doctor#patient ...
```

You do not include `i.patient` because the coding for patient has no meaning except within doctor. Patient 1 is Fred for doctor 1 and Karen for doctor 2, etc.

`margins` provides an option to help account for the structure of nested models. The `within(`*varlist*`)` option specifies that `margins` estimate and report a set of margins for the value combinations of *varlist*. We might type

```
. margins, within(doctor)
```

Margin calculations are performed first for `doctor` = 1, then for `doctor` = 2, and so on.

Sometimes you need to specify `within()`, and other times you do not. Let's consider the particular model

```
. regress y i.doctor doctor#patient i.sex sex#doctor#patient
```

The guidelines are the following:

1. You may compute overall margins by typing
   `margins`.
2. You may compute overall margins within levels of a nesting factor by typing
   `margins, within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing
   `margins patient, within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing
   `margins sex`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

For examples using `within()`, see [R] **anova**.

Margins with nested designs as though the data were balanced

To obtain margins with nested designs as though the data were balanced, the guidelines are the same as above except that 1) you add the `asbalanced` option and 2) whenever you do not specify `within()`, you specify `emptycells(reweight)`. The updated guidelines are

1. You may compute overall margins by typing
   `margins, asbalanced emptycells(reweight)`.
2. You may compute overall margins within levels of a nesting factor by typing
   `margins, asbalanced within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing
   `margins patient, asbalanced within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing
   `margins sex, asbalanced emptycells(reweight)`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

Just as explained in *Using fvset design*, rather than specifying the `asbalanced` option, you may set the balancing characteristic on the factor variables once and for all by using the command `fvset design asbalanced` *varlist*.

❑ Technical note

Specifying either `emptycells(reweight)` or `within(`*varlist*`)` causes `margins` to rebalance over all empty cells in your model. If you have interactions in your model that are not involved in the nesting, `margins` will lose its ability to detect estimability.

❑

❑ Technical note

Careful readers will note that the description of `within(`*varlist*`)` matches closely the description of `over(`*varlist*`)`. The concept of nesting is similar to the concept of subpopulations. `within()` differs from `over()` in that it gracefully handles the missing cells when margins are computed as balanced.

❑

Coding of nested designs

In the *Introduction* to this section, we showed a coding of the nested variable `patient`, where the coding started over with each `doctor`:

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	1	Karen
2	2	Hank

That coding style is not required. The data could just as well have been coded

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	4	Karen
2	5	Hank

or even

Doctor	Patient	Name
1	1037239	Fred
1	2223942	Mary
1	0611393	Bob
2	4433329	Karen
2	6110271	Hank

Actually, either of the above two alternatives are better than the first one because `margins` will be better able to give you feedback about estimability should you make a mistake following the guidelines. On the other hand, both of these two alternatives require more memory at the estimation step. If you run short of memory, you will need to recode your patient ID to the first coding style, which you could do by typing

```
. sort doctor patient
. by doctor: gen newpatient = _n
```

Alternatively, you can `set emptycells drop` and continue to use your patient ID variable just as it is coded. If you do this, we recommend that you remember to type `set emptycells keep` when you are finished; `margins` is better able to determine estimability that way. If you regularly work with large nested models, you can `set emptycells keep, permanently` so that the setting persists across sessions. See [R] **set emptycells**.

Special topics

Requirements for model specification

The results that `margins` reports are based on the most recently fit model or, in Stata jargon, the most recently issued estimation command. Here we discuss 1) mechanical requirements for how you specify that estimation command, 2) work-arounds to use when those restrictions prove impossible, and 3) requirements for `margins`' `predict(`*pred_opt*`)` option to work.

Concerning 1, when you specify the estimation command, covariates that are logically factor variables must be Stata factor variables, and that includes indicator variables, binary variables, and dummies. It will not do to type

```
. regress y ... female ...
```

even if `female` is a 0/1 variable. You must type

```
. regress y ... i.female ...
```

If you violate this rule, you will not get incorrect results, but you will discover that you will be unable to obtain margins on `female`:

```
. margins female
factor female not found in e(b)
r(111);
```

It is also important that if the same continuous variable appears in your model more than once, differently transformed, those transforms be performed via Stata's factor-variable notation. It will not do to type

```
. generate age2 = age^2
. regress y ... age age2 ...
```

You must type

```
. regress y ... age c.age#c.age ...
```

You must do that because `margins` needs to know everywhere that variable appears in the model if it is to be able to set covariates to fixed values.

Concerning 2, sometimes the transformations you desire may not be achievable using the factor-variable notation; in those situations, there is a work-around. Let's assume you wish to estimate

```
. generate age1_5 = age^1.5
. regress y ... age age1_5 ...
```

There is no factor-variable notation for including `age` and $\texttt{age}^{1.5}$ in a model, so obviously you are going to obtain the estimates by typing just what we have shown. In what follows, it would be okay if there are interactions of `age` and `age1_5` with other variables specified by the factor-variable notation, so the model could just as well be

```
. regress y ... age age1_5 sex#c.age sex#c.age1_5 ...
```

Let's assume you have fit one of these two models. On any subsequent `margins` command where you leave age free to vary, there will be no issue. You can type

```
. margins female
```

and results will be correct. Issues arise when you attempt to fix age at predetermined values. The following would produce incorrect results:

```
. margins female, at(age=20)
```

The results would be incorrect because they leave age1_5 free to vary, and, logically, fixing age implies that age1_5 should also be fixed. Because we were unable to state the relationship between age and age1_5 using the factor-variable notation, margins does not know to fix age1_5 at $20^{1.5}$ when it fixes age at 20. To get the correct results, you must fix the value of age1_5 yourself:

```
. margins female, at(age=20 age1_5=89.442719)
```

That command produces correct results. In the command, 89.442719 is $20^{1.5}$.

In summary, when there is a functional relationship between covariates of your model and that functional relationship is not communicated to margins via the factor-variable notation, then it becomes your responsibility to ensure that all variables that are functionally related are set to the appropriate fixed values when any one of them is set to a fixed value.

Concerning 3, we wish to amend our claim that you can calculate margins for anything that predict will produce. We need to add a qualifier. Let us show you an example where the statement is not true. After regress, predict will predict something it calls pr(*a*,*b*), which is the probability $a \leq y \leq b$. Yet if we attempted to use pr() with margins after estimation by regress, we would obtain

```
. margins sex, predict(pr(10,20))
prediction is a function of possibly stochastic quantities other than e(b)
r(498);
```

What we should have stated was that you can calculate margins for anything that predict will produce for which all the estimated quantities used in its calculation appear in e(V), the estimated VCE. pr() is a function of $\boldsymbol{\beta}$, the estimated coefficients, and of s^2, the estimated variance of the residual. regress does not post the variance of the residual variance (sic) in e(V), or even estimate it, and therefore, predict(pr(10,20)) cannot be specified with margins after estimation by regress.

It is unlikely that you will ever encounter these kinds of problems because there are so few predictions where the components are not posted to e(V). If you do encounter the problem, the solution may be to specify nose to suppress the standard-error calculation. If the problem is not with computing the margin, but with computing its standard error, margins will report the result:

```
. margins sex, predict(pr(10,20)) nose
  (output appears with SEs, tests, and CIs left blank)
```

❑ Technical note

Programmers: If you run into this after running an estimation command that you have written, be aware that as of Stata 11, you are supposed to set in e(marginsok) the list of options allowed with predict that are okay to use with margins. When that list is not set, margins looks for violations of its assumptions and, if it finds any, refuses to proceed.

❑

Estimability of margins

Sometimes `margins` will report that a margin cannot be estimated:

```
. use http://www.stata-press.com/data/r12/estimability, clear
(margins estimability)
. regress y sex##group
  (output omitted)
. margins sex
Predictive margins                                Number of obs   =         69
Model VCE    : OLS
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	21	.8500245	24.71	0.000	19.33398	22.66602
1	.	(not estimable)				

In the above output, the margin for `sex` $= 0$ is estimated, but the margin for `sex` $= 1$ is not estimable. This occurs because of empty cells. An empty cell is an interaction of levels of two or more factor variables for which you have no data. In the example, the lack of estimability arises because we have two empty cells:

```
. table sex group
```

	group				
sex	1	2	3	4	5
0	2	9	27	8	2
1	9	9	3		

To calculate the marginal mean response for `sex` $= 1$, we have no responses to average over for `group` $= 4$ and `group` $= 5$. We obviously could calculate that mean for the observations that really are `sex` $= 1$, but remember, the marginal calculation for `sex` $= 1$ treats everyone as if female, and we will thus have 8 and 2 observations for which we have no basis for estimating the response.

There is no solution for this problem unless you are willing to treat the data as if it were balanced and adjust your definition of a margin; see *Balancing in the presence of empty cells*.

Manipulability of tests

Manipulability is a problem that arises with some tests, and in particular, arises with Wald tests. Tests of margins are based on Wald tests, hence our interest. This is a generic issue and not specific to the `margins` command.

Let's understand the problem. Consider performing a test of whether some statistic ϕ is 0. Whatever the outcome of that test, it would be desirable if the outcome were the same were we to test whether the sqrt(ϕ) were 0, or whether ϕ^2 were 0, or whether any other monotonic transform of ϕ were 0 (for ϕ^2, we were considering only the positive half of the number line). If a test does not have that property, it is manipulable.

Wald tests are manipulable, and that means the tests produced by `margins` are manipulable. You can see this for yourself by typing

```
. use http://www.stata-press.com/data/r12/margex, clear
. replace y = y - 65
. regress y sex##group
. margins
. margins, expression(predict(xb)^2)
```

We would prefer if the test against zero produced by `margins` was equal to the test produced by `margins, expression(predict(xb)^2)`. But alas, they produce different results. The first produces $z = 12.93$, and the second produces $z = 12.57$.

The difference is not much in our example, but behind the scenes, we worked to make it small. We subtracted 65 from `y` so that the experiment would be for a case where it might be reasonable that you would be testing against 0. One does not typically test whether the mean income in the United States is zero or whether the mean blood pressure of live patients is zero. Had we left `y` as it was originally, we would have obtained $z = 377$ and $z = 128$. We did not want to show that comparison to you first because the mean of `y` is so far from 0 that you probably would never be testing it. The corresponding difference in ϕ is tiny.

Regardless of the example, it is important that you base your tests in the metric where the likelihood surface is most quadratic. For further discussion on manipulability, see *Manipulability* in [R] **predictnl**.

This manipulability is not limited to Wald tests after estimation; you can also see the manipulability of results produced by linear regression just by applying nonlinear transforms to a covariate (Phillips and Park 1988; Gould 1996).

Using margins after the estimates use command

Assume you fit and used `estimates save` (see [R] **estimates save**) to save the estimation results:

```
. regress y sex##group age c.age*c.age if site==1
. ...
. estimates save mymodel
(file mymodel.ster saved)
```

Later, perhaps in a different Stata session, you reload the estimation results by typing

```
. estimates use mymodel
```

You plan to use `margins` with the reloaded results. You must remember that `margins` bases its results not only on the current estimation results but also on the current data in memory. Before you can use `margins`, you must reload the dataset on which you fit the model or, if you wish to produce standardized margins, some other dataset.

```
. use mydata, clear
(data for fitting models)
```

If the dataset you loaded contained the data for standardization, you can stop reading; you know that to produce standardized margins, you need to specify the `noesample` option.

We reloaded the original data and want to produce margins for the estimation sample. In addition to the data, `margins` requires that `e(sample)` be set, as `margins` will remind us:

```
. margins sex
e(sample) does not identify the estimation sample
r(322);
```

The best solution is to use estimates esample to rebuild e(sample):

```
. estimates esample: y sex group age if site==1
```

If we knew we had no missing values in y and the covariates, we could type

```
. estimates esample: if site==1
```

Either way, margins would now work:

```
. margins sex
(usual output appears)
```

There is an alternative. We do not recommend it, but we admit that we have used it. Rather than rebuilding e(sample), you can use margins' noesample option to tell margins to skip using e(sample). You could then specify the appropriate if statement (if necessary) to identify the estimation sample:

```
. estimates use mymodel
. use mydata, clear
(data for fitting models)
. margins sex if !missing(y, sex, group age) & site==1, noesample
(usual output appears)
```

In the above, we are not really running on a sample different from the estimation sample; we are merely using noesample to fool margins, and then we are specifying on the margins command the conditions equivalent to re-create e(sample).

If we wish to obtain vce(unconditional) results, however, noesample will be insufficient. We must also specify the force option,

```
. margins sex if !missing(y, sex, group age) & site==1,
> vce(unconditional) noesample force
(usual output appears)
```

Regardless of the approach you choose—resetting e(sample) or specifying noesample and possibly force—make sure you are right. In the vce(delta) case, you want to be right to ensure that you obtain the results you want. In the vce(unconditional) case, you need to be right because otherwise results will be statistically invalid.

Syntax of at()

In at(*atspec*), *atspec* may contain one or more of the following specifications:

varlist

(*stat*) *varlist*

varname = #

varname = (*numlist*)

where

1. *varname*s must be covariates in the previously fit model (estimation command).
2. Variable names (whether in *varname* or *varlist*) may be continuous variables, factor variables, or specific level variables, such as age, group, or 3.group.

3. *varlist* may also be one of three standard lists:
    a. _all (all covariates),
    b. _factor (all factor-variable covariates), or
    c. _continuous (all continuous covariates).
4. Specifications are processed from left to right with latter specifications overriding previous ones.
5. *stat* can be any of the following:

stat	Description	Variables allowed
asobserved	at observed values in the sample (default)	all
mean	means (default for *varlist*)	all
median	medians	continuous
p1	1st percentile	continuous
p2	2nd percentile	continuous
...	3rd–49th percentiles	continuous
p50	50th percentile (same as median)	continuous
...	51st–97th percentiles	continuous
p98	98th percentile	continuous
p99	99th percentile	continuous
min	minimums	continuous
max	maximums	continuous
zero	fixed at zero	continuous
base	base level	factors
asbalanced	all levels equally probable and sum to 1	factors

Any *stat* except zero, base, and asbalanced may be prefixed with an o to get the overall statistic—the sample over all over() groups. For example, omean, omedian, and op25. Overall statistics differ from their correspondingly named statistics only when the over() or within() option is specified. When no *stat* is specified, mean is assumed.

Estimation commands that may be used with margins

margins may be used after most estimation commands.

margins cannot be used after estimation commands that do not produce full variance matrices, such as exlogistic and expoisson (see [R] **exlogistic** and [R] **expoisson**).

margins is all about covariates and cannot be used after estimation commands that do not post the covariates, which eliminates gmm (see [R] **gmm**).

margins cannot be used after estimation commands that have an odd data organization, and that excludes asclogit, asmprobit, asroprobit, and nlogit (see [R] **asclogit**, [R] **asmprobit**, [R] **asroprobit**, and [R] **nlogit**).

Glossary

adjusted mean. A *margin* when the response is the linear predictor from linear regression, ANOVA, etc. For some authors, adjusting also implies adjusting for unbalanced data. See *Obtaining margins of responses* and see *Obtaining margins as though the data were balanced*.

average marginal effect. See *marginal effect and average marginal effect*.

average partial effect. See *partial effect and average partial effect*.

conditional margin. A *margin* when the response is evaluated at fixed values of all the covariates. If any covariates are left to vary, the margin is called a predictive margin.

effect. The effect of x is the derivative of the *response* with respect to covariate x, or it is the difference in responses caused by a discrete change in x. Also see *marginal effect*.

The effect of x measures the change in the response for a change in x. Derivatives or differences might be reported as elasticities. If x is continuous, the effect is measured continuously. If x is a factor, the effect is measured with respect to each level of the factor and may be calculated as a discrete difference or as a continuous change, as measured by the derivative. `margins` calculates the discrete difference by default and calculates the derivative if the `continuous` option is specified.

elasticity and **semielasticity**. The elasticity of y with respect to x is $d(\ln y)/d(\ln x) = (x/y)\times(dy/dx)$, which is approximately equal to the proportional change in y for a proportional change in x.

The semielasticity of y with respect to x is either 1) $dy/d(\ln x) = x \times (dy/dx)$ or 2) $d(\ln y)/dx = (1/y) \times (dy/dx)$, which is approximately 1) the change in y for a proportional change in x or 2) the proportional change in y for a change in x.

empty cell. An interaction of levels of two or more factor variables for which you have no data. For instance, you have sex interacted with group in your model, and in your data there are no females in group 1. Empty cells affect which margins can be estimated; see *Estimability of margins*.

estimability. Estimability concerns whether a margin can be uniquely estimated (identified); see *Estimability of margins*.

estimated marginal mean. This is one of the few terms that has the same meaning across authors. An estimated marginal mean is a margin assuming the levels of each factor covariate are equally likely (balanced), including interaction terms. This is obtained using `margins'` `asbalanced` option. In addition, there is an alternate definition of estimated marginal mean in which margins involving empty cells are redefined so that they become estimable. This is invoked by `margins'` `emptycells(reweight)` option. See *Balancing in the presence of empty cells*.

least-squares mean. Synonym for *estimated marginal mean*.

margin. A statistic calculated from predictions or other statistics of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The prediction or other statistic on which the margin is based is called the response.

If all the covariates are fixed, then the margin is called a conditional margin. If any covariates are left to vary, the margin is called a predictive margin.

In this documentation, we divide margins on the basis of whether the statistic is a response or a derivative of a response; see *Obtaining margins of responses* and *Obtaining margins of derivatives of responses*.

marginal effect and **average marginal effect**. The marginal effect of x is the *margin* of the *effect* of x. The term is popular with social scientists, and because of that, you might think the word marginal in marginal effect means derivative because of terms like marginal cost and marginal revenue. Marginal used in that way, however, refers to the derivative of revenue and the derivative

of cost; it refers to the numerator, whereas marginal effect refers to the denominator. Moreover, *effect* is already a derivative or difference.

Some researchers interpret marginal in marginal effect to mean instantaneous, and thus a marginal effect is the instantaneous derivative rather than the discrete first-difference, corresponding to `margins`' `continuous` option. Researchers who use marginal in this way refer to the discrete difference calculation of an effect as a partial effect.

Other researchers define marginal effect to be the margin when all covariates are held fixed and the average marginal effect when some covariates are not fixed.

out-of-sample prediction. Predictions made in one dataset using the results from a model fit on another. Sample here refers to the sample on which the model was fit, and out-of-sample refers to the dataset on which the predictions are made.

partial effect and **average partial effect**. Some authors restrict the term *marginal effect* to mean derivatives and use the term partial effect to denote discrete differences; see *marginal effect and average marginal effect*.

population marginal mean. The theoretical (true) value that is estimated by *estimated marginal mean*. We avoid this term because it can be confused with the concept of a population in survey statistics, with which the population marginal mean has no connection.

posting results, **posting margins**. A Stata concept having to do with saving the results from the `margins` command in `e()` so that those results can be used as if they were estimation results, thus allowing the subsequent use of postestimation commands, such as `test`, `testnl`, `lincom`, and `nlcom` (see [R] **test**, [R] **testnl**, [R] **lincom**, and [R] **nlcom**). This is achieved by specifying `margins`' `post` option. See *Example 10: Testing margins—contrasts of margins*.

predictive margin. A *margin* in which all the covariates are not fixed. When all covariates are fixed, it is called a *conditional margin*.

recycled prediction. A synonym for *predictive margin*.

response. A prediction or other statistic derived from combining the parameter estimates of a fitted model with data or specified values on covariates. Derivatives of responses are themselves responses. Responses are what we take *margins* of.

standardized margin. The margin calculated on data different from the data used to fit the model. The term standardized is usually reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

subpopulation. A subset of your sample that represents a subset of the population, such as the males in a sample of people. In survey contexts when it is desired to account for sampling of the covariates, standard errors for marginal statistics and effects need to account for both the population and the subpopulation. This is accomplished by specifying the `vce(unconditional)` option and one of the `subpop()` or `over()` options. In fact, the above is allowed even when your data are not `svyset` because `vce(unconditional)` implies that the sample represents a population.

Saved results

`margins` saves the following in `r()`:

Scalars

`r(N)`	number of observations
`r(N_sub)`	subpopulation observations
`r(N_clust)`	number of clusters
`r(N_psu)`	number of sampled PSUs, survey data only
`r(N_strata)`	number of strata, survey data only
`r(df_r)`	variance degrees of freedom, survey data only
`r(N_poststrata)`	number of post strata, survey data only
`r(k_margins)`	number of terms in *marginlist*
`r(k_by)`	number of subpopulations
`r(k_at)`	number of `at()` options
`r(level)`	confidence level of confidence intervals

Macros

`r(cmd)`	`margins`
`r(cmdline)`	command as typed
`r(est_cmd)`	`e(cmd)` from original estimation results
`r(est_cmdline)`	`e(cmdline)` from original estimation results
`r(title)`	title in output
`r(subpop)`	*subspec* from `subpop()`
`r(model_vce)`	*vcetype* from estimation command
`r(model_vcetype)`	Std. Err. title from estimation command
`r(vce)`	*vcetype* specified in `vce()`
`r(vcetype)`	title used to label Std. Err.
`r(clustvar)`	name of cluster variable
`r(margins)`	*marginlist*
`r(predict_label)`	label from `predict()`
`r(expression)`	response expression
`r(xvars)`	*varlist* from `dydx()`, `dyex()`, `eydx()`, or `eyex()`
`r(derivatives)`	"", "dy/dx", "dy/ex", "ey/dx", "ey/ex"
`r(over)`	*varlist* from `over()`
`r(within)`	*varlist* from `within()`
`r(by)`	union of `r(over)` and `r(within)` lists
`r(by#)`	interaction notation identifying the #th subpopulation
`r(atstats#)`	the #th `at()` specification
`r(emptycells)`	*empspec* from `emptycells()`
`r(mcmethod)`	*method* from `mcompare()`
`r(mcadjustall)`	`adjustall` or empty

Matrices

`r(b)`	estimates
`r(V)`	variance–covariance matrix of the estimates
`r(Jacobian)`	Jacobian matrix
`r(_N)`	sample size corresponding to each margin estimate
`r(at)`	matrix of values from the `at()` options
`r(chainrule)`	chainrule information from the fitted model
`r(error)`	margin estimability codes; `0` means estimable, `8` means not estimable
`r(table)`	matrix containing the margins with their standard errors, test statistics, p-values, and confidence intervals

margins with the post option also saves the following in e():

Scalars

e(N)	number of observations
e(N_sub)	subpopulation observations
e(N_clust)	number of clusters
e(N_psu)	number of sampled PSUs, survey data only
e(N_strata)	number of strata, survey data only
e(df_r)	variance degrees of freedom, survey data only
e(N_poststrata)	number of post strata, survey data only
e(k_margins)	number of terms in *marginlist*
e(k_by)	number of subpopulations
e(k_at)	number of at() options

Macros

e(cmd)	margins
e(cmdline)	command as typed
e(est_cmd)	e(cmd) from original estimation results
e(est_cmdline)	e(cmdline) from original estimation results
e(title)	title in estimation output
e(subpop)	*subspec* from subpop()
e(model_vce)	*vcetype* from estimation command
e(model_vcetype)	Std. Err. title from estimation command
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(clustvar)	name of cluster variable
e(margins)	*marginlist*
e(predict_label)	label from predict()
e(expression)	prediction expression
e(xvars)	*varlist* from dydx(), dyex(), eydx(), or eyex()
e(derivatives)	"", "dy/dx", "dy/ex", "ey/dx", "ey/ex"
e(over)	*varlist* from over()
e(within)	*varlist* from within()
e(by)	union of r(over) and r(within) lists
e(by#)	interaction notation identifying the #th subpopulation
e(atstats#)	the #th at() specification
e(emptycells)	*empspec* from emptycells()
e(mcmethod)	*method* from mcompare()
e(mcadjustall)	adjustall or empty

Matrices

e(b)	estimates
e(V)	variance–covariance matrix of the estimates
e(Jacobian)	Jacobian matrix
e(_N)	sample size corresponding to each margin estimate
e(at)	matrix of values from the at() options
e(chainrule)	chainrule information from the fitted model

Functions

e(sample)	marks estimation sample

Methods and formulas

margins is implemented as an ado-file.

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. There are many names for the different statistics that margins can compute: estimates marginal means (see Searle, Speed, and Milliken [1980]), predictive margins (see Graubard and Korn [2004]), marginal effects (see Greene [2012]), and average marginal/partial effects (see Wooldridge [2010] and Bartus [2005]).

Methods and formulas are presented under the following headings:

Notation
Marginal effects
Fixing covariates and balancing factors
Estimable functions
Standard errors conditional on the covariates
Unconditional standard errors

Notation

Let $\boldsymbol{\theta}$ be the vector of parameters in the current model fit, let $\mathbf{z}$ be a vector of covariate values, and let $f(\mathbf{z}, \boldsymbol{\theta})$ be a scalar-valued function returning the value of the predictions of interest. The following table illustrates the parameters and default prediction for several of Stata's estimation commands.

Command	$\boldsymbol{\theta}$	$\mathbf{z}$	$f(\mathbf{z}, \boldsymbol{\theta})$
`regress`	$\boldsymbol{\beta}$	$\mathbf{x}$	$\mathbf{x}\boldsymbol{\beta}$
`cloglog`	$\boldsymbol{\beta}$	$\mathbf{x}$	$1 - e^{-e^{x\beta}}$
`logit`	$\boldsymbol{\beta}$	$\mathbf{x}$	$1/(1 + e^{-x\beta})$
`poisson`	$\boldsymbol{\beta}$	$\mathbf{x}$	$e^{x\beta}$
`probit`	$\boldsymbol{\beta}$	$\mathbf{x}$	$\Phi(\mathbf{x}\boldsymbol{\beta})$
`biprobit`	$\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \rho$	$\mathbf{x}_1, \mathbf{x}_2$	$\Phi_2(\mathbf{x}_1\boldsymbol{\beta}_1, \mathbf{x}_2\boldsymbol{\beta}_2, \rho)$
`mlogit`	$\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \ldots, \boldsymbol{\beta}_k$	$\mathbf{x}$	$e^{-x\beta_1}/(\sum_i e^{-x\beta_i})$
`nbreg`	$\boldsymbol{\beta}$, $\ln\alpha$	$\mathbf{x}$	$e^{x\beta}$

$\Phi()$ and $\Phi_2()$ are cumulative distribution functions: $\Phi()$ for the standard normal distribution and $\Phi_2()$ for the standard bivariate normal distribution.

`margins` computes estimates of

$$p(\boldsymbol{\theta}) = \frac{1}{M_{S_\mathrm{p}}} \sum_{j=1}^{M} \delta_j(S_\mathrm{p}) f(\mathbf{z}_j, \boldsymbol{\theta})$$

where $\delta_j(S_\mathrm{p})$ identifies elements within the subpopulation S_p (for the prediction of interest),

$$\delta_j(S_\mathrm{p}) = \begin{cases} 1, & j \in S_\mathrm{p} \\ 0, & j \notin S_\mathrm{p} \end{cases}$$

M_{S_p} is the subpopulation size,

$$M_{S_\mathrm{p}} = \sum_{j=1}^{M} \delta_j(S_\mathrm{p})$$

and M is the population size.

Let $\widehat{\boldsymbol{\theta}}$ be the vector of parameter estimates. Then `margins` estimates $p(\boldsymbol{\theta})$ via

$$\widehat{p} = \frac{1}{w_\cdot} \sum_{j=1}^{N} \delta_j(S_\mathrm{p}) w_j f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}})$$

where

$$w_{\cdot} = \sum_{j=1}^{N} \delta_j(S_{\mathrm{p}}) w_j$$

$\delta_j(S_{\mathrm{p}})$ indicates whether observation j is in subpopulation S_{p}, w_j is the weight for the jth observation, and N is the sample size.

Marginal effects

`margins` also computes marginal/partial effects. For the marginal effect of continuous covariate x, `margins` computes

$$\widehat{p} = \frac{1}{w_{\cdot}} \sum_{j=1}^{N} \delta_j(S_{\mathrm{p}}) w_j h(\mathbf{z}_j, \widehat{\boldsymbol{\theta}})$$

where

$$h(\mathbf{z}, \boldsymbol{\theta}) = \frac{\partial f(\mathbf{z}, \boldsymbol{\theta})}{\partial x}$$

The marginal effect for level k of factor variable A is the simple contrast (a.k.a. difference) comparing its margin with the margin at the base level.

$$h(\mathbf{z}, \boldsymbol{\theta}) = f(\mathbf{z}, \boldsymbol{\theta} | A = k) - f(\mathbf{z}, \boldsymbol{\theta} | A = \mathrm{base})$$

Fixing covariates and balancing factors

`margins` controls the values in each $\mathbf{z}$ vector through the *marginlist*, the `at()` option, the `atmeans` option, and the `asbalanced` and `emptycells()` options. Suppose $\mathbf{z}$ is composed of the elements from the equation specification

```
A##B x
```

where `A` is a factor variable with a levels, `B` is a factor variable with b levels, and `x` is a continuous covariate. To simplify the notation for this discussion, assume the levels of `A` and `B` start with 1 and are contiguous. Then

$$\mathbf{z} = (A_1, \ldots, A_a, B_1, \ldots, B_b, A_1B_1, A_1B_2, \ldots, A_aB_b, x, 1)$$

where A_i, B_j, and A_iB_j represent the indicator values for the factor variables `A` and `B` and the interaction `A#B`.

When factor `A` is in the *marginlist*, `margins` replaces `A` with i and then computes the mean of the subsequent prediction, for $i = 1, \ldots, a$. When the interaction term `A#B` is in the *marginlist*, `margins` replaces `A` with i and `B` with j, and then computes the mean of the subsequent prediction, for all combinations of $i = 1, \ldots, a$ and $j = 1, \ldots, b$.

The `at()` option sets model covariates to fixed values. For example, `at(x=15)` causes `margins` to temporarily set x to 15 for each observation in the dataset before computing any predictions. Similarly, `at((median) x)` causes `margins` to temporarily set x to the median of `x` using the current dataset.

When factor variable `A` is specified as `asbalanced`, `margins` sets each A_i to $1/a$. Thus each $\mathbf{z}$ vector will look like

$$\mathbf{z} = (1/a, \ldots, 1/a, B_1, \ldots, B_b, B_1/a, B_2/a, \ldots, B_b/a, x, 1)$$

If `B` is also specified as `asbalanced`, then each B_j is set to $1/b$, and each $\mathbf{z}$ vector will look like

$$\mathbf{z} = (1/a, \ldots, 1/a, 1/b, \ldots, 1/b, 1/ab, 1/ab, \ldots, 1/ab, x, 1)$$

If `emptycells(reweight)` is also specified, then `margins` uses a different balancing weight for each element of $\mathbf{z}$, depending on how many empty cells the element is associated with. Let δ_{ij} indicate that the ijth cell of `A#B` was observed in the estimation sample.

$$\delta_{ij} = \begin{cases} 0, & \texttt{A}=i \text{ and } \texttt{B}=j \text{ was an empty cell} \\ 1, & \text{otherwise} \end{cases}$$

For the grand margin, the affected elements of $\mathbf{z}$ and their corresponding balancing weights are

$$A_i = \frac{\sum_j \delta_{ij}}{\sum_k \sum_j \delta_{kj}}$$

$$B_j = \frac{\sum_i \delta_{ij}}{\sum_i \sum_k \delta_{ik}}$$

$$A_i B_j = \frac{\delta_{ij}}{\sum_k \sum_l \delta_{kl}}$$

For the jth margin of `B`, the affected elements of $\mathbf{z}$ and their corresponding balancing weights are

$$A_i = \frac{\delta_{ij}}{\sum_k \delta_{kj}}$$

$$B_l = \begin{cases} 1, & \text{if } l = j \text{ and not all } \delta_{ij} \text{ are zero} \\ 0, & \text{otherwise} \end{cases}$$

$$A_i B_l = \frac{\delta_{il}}{\sum_k \delta_{kl}} B_l$$

Estimable functions

The fundamental idea behind estimable functions is clearly defined in the statistical literature for linear models; see Searle (1971). Assume that we are working with the following linear model:

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where $\mathbf{y}$ is an $N \times 1$ vector of responses, $\mathbf{X}$ is an $N \times p$ matrix of covariate values, $\mathbf{b}$ is a $p \times 1$ vector of coefficients, and $\mathbf{e}$ is a vector of random errors. Assuming a constant variance for the random errors, the normal equations for the least-squares estimator, $\widehat{\mathbf{b}}$, are

$$\mathbf{X}'\mathbf{X}\widehat{\mathbf{b}} = \mathbf{X}'\mathbf{y}$$

When $\mathbf{X}$ is not of full column rank, we will need a generalized inverse (g-inverse) of $\mathbf{X}'\mathbf{X}$ to solve for $\widehat{\mathbf{b}}$. Let $\mathbf{G}$ be a g-inverse of $\mathbf{X}'\mathbf{X}$.

Searle (1971) defines a linear function of the parameters as *estimable* if it is identically equal to some linear function of the expected values of the $\mathbf{y}$ vector. Let $\mathbf{H} = \mathbf{G}\mathbf{X}'\mathbf{X}$. Then this definition simplifies to the following rule:

$$\mathbf{z}\mathbf{b} \text{ is estimable if } \mathbf{z} = \mathbf{z}\mathbf{H}$$

`margins` generalizes this to nonlinear functions by assuming the prediction function $f(\mathbf{z}, \boldsymbol{\theta})$ is a function of one or more of the linear predictions from the equations in the model that $\boldsymbol{\theta}$ represents.

$$f(\mathbf{z}, \boldsymbol{\theta}) = h(\mathbf{z}_1\boldsymbol{\beta}_1, \mathbf{z}_2\boldsymbol{\beta}_2, \ldots, \mathbf{z}_k\boldsymbol{\beta}_k)$$

$\mathbf{z}_i\boldsymbol{\beta}_i$ is considered estimable if $\mathbf{z}_i = \mathbf{z}_i\mathbf{H}_i$, where $\mathbf{H}_i = \mathbf{G}_i\mathbf{X}_i'\mathbf{X}_i$, $\mathbf{G}_i$ is a g-inverse for $\mathbf{X}_i'\mathbf{X}_i$, and $\mathbf{X}_i$ is the matrix of covariates from the ith equation of the fitted model. `margins` considers $p(\boldsymbol{\theta})$ to be estimable if every $\mathbf{z}_i\boldsymbol{\beta}_i$ is estimable.

Standard errors conditional on the covariates

By default, `margins` uses the delta method to estimate the variance of $\widehat{p}$.

$$\widehat{\text{Var}}(\widehat{p} \,|\, \mathbf{z}) = \mathbf{v}'\mathbf{V}\mathbf{v}$$

where $\mathbf{V}$ is a variance estimate for $\widehat{\boldsymbol{\theta}}$ and

$$\mathbf{v} = \left.\frac{\partial \widehat{p}}{\partial \boldsymbol{\theta}}\right|_{\theta=\widehat{\theta}}$$

This variance estimate is conditional on the $\mathbf{z}$ vectors used to compute the marginalized predictions.

Unconditional standard errors

`margins` with the `vce(unconditional)` option uses linearization to estimate the unconditional variance of $\widehat{\boldsymbol{\theta}}$. Linearization uses the variance estimator for the total of a score variable for $\widehat{p}$ as an approximate estimator for $\text{Var}(\widehat{p})$; see [SVY] **variance estimation**. `margins` requires that the model was fit using some form of linearized variance estimator and that `predict, scores` computes the appropriate score values for the linearized variance estimator.

The score for $\widehat{p}$ from the jth observation is given by

$$s_j = \frac{\partial \widehat{p}}{\partial w_j} = -\frac{\delta_j(S_{\rm p})}{w.}\widehat{p} + \frac{\delta_j(S_{\rm p})}{w.} f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}}) + \frac{1}{w.}\sum_{i=1}^{N} \delta_i(S_{\rm p}) w_i \frac{\partial f(\mathbf{z}_i, \widehat{\boldsymbol{\theta}})}{\partial w_j}$$

The remaining partial derivative can be decomposed using the chain rule.

$$\frac{\partial f(\mathbf{z}_i, \widehat{\boldsymbol{\theta}})}{\partial w_j} = \left(\left. \frac{\partial f(\mathbf{z}_i, \boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\theta=\widehat{\theta}} \right) \left(\frac{\partial \widehat{\boldsymbol{\theta}}}{\partial w_j} \right)'$$

This is the inner product of two vectors, the second of which is not a function of the i index. Thus the score is

$$s_j = -\frac{\delta_j(S_{\rm p})}{w.}\widehat{p} + \frac{\delta_j(S_{\rm p})}{w.} f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}}) + \left(\left. \frac{\partial \widehat{p}}{\partial \boldsymbol{\theta}} \right|_{\theta=\widehat{\theta}} \right) \left(\frac{\partial \widehat{\boldsymbol{\theta}}}{\partial w_j} \right)'$$

If $\widehat{\boldsymbol{\theta}}$ was derived from a system of equations (such as in linear regression or maximum likelihood estimation), then $\widehat{\boldsymbol{\theta}}$ is the solution to

$$\mathbf{G}(\boldsymbol{\theta}) = \sum_{j=1}^{N} \delta_j(S_{\rm m}) w_j \mathbf{g}(\boldsymbol{\theta}, \mathbf{y}_j, \mathbf{x}_j) = \mathbf{0}$$

where $S_{\rm m}$ identifies the subpopulation used to fit the model, $\mathbf{g}()$ is the model's gradient function, and $\mathbf{y}_j$ and $\mathbf{x}_j$ are the values of the dependent and independent variables for the jth observation. We can use linearization to derive a first-order approximation for $\partial\widehat{\boldsymbol{\theta}}/\partial w_j$.

$$\mathbf{G}(\widehat{\boldsymbol{\theta}}) \approx \mathbf{G}(\boldsymbol{\theta}_0) + \left. \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\theta=\theta_0} (\widehat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0)$$

Let $\mathbf{H}$ be the Hessian matrix

$$\mathbf{H} = \left. \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\theta=\theta_0}$$

Then

$$\widehat{\boldsymbol{\theta}} \approx \boldsymbol{\theta}_0 + (-\mathbf{H})^{-1}\mathbf{G}(\boldsymbol{\theta}_0)$$

and

$$\frac{\partial\widehat{\boldsymbol{\theta}}}{\partial w_j} \approx (-\mathbf{H})^{-1}\left.\frac{\partial\mathbf{G}(\boldsymbol{\theta})}{\partial w_j}\right|_{\theta=\widehat{\theta}} = (-\mathbf{H})^{-1}\delta_j(S_{\rm m})\mathbf{g}(\widehat{\boldsymbol{\theta}},\mathbf{y}_j,\mathbf{x}_j)$$

The computed value of the score for $\widehat{p}$ for the jth observation is

$$s_j = \mathbf{v}'\mathbf{u}_j$$

where

$$\mathbf{v} = \begin{bmatrix} -\dfrac{\widehat{p}}{w.} \\ \dfrac{1}{w.} \\ \dfrac{\partial\widehat{p}}{\partial\widehat{\boldsymbol{\theta}}}(-\mathbf{H})^{-1} \end{bmatrix}$$

and

$$\mathbf{u}_j = \begin{bmatrix} \delta_j(S_{\rm p}) \\ \delta_j(S_{\rm p})f(\mathbf{z}_j,\widehat{\boldsymbol{\theta}}) \\ \delta_j(S_{\rm m})\mathbf{g}(\widehat{\boldsymbol{\theta}},\mathbf{y}_j,\mathbf{x}_j) \end{bmatrix}$$

Thus the variance estimate for $\widehat{p}$ is

$$\widehat{\rm Var}(\widehat{p}) = \mathbf{v}'\widehat{\rm Var}(\widehat{\mathbf{U}})\mathbf{v}$$

where

$$\widehat{\mathbf{U}} = \sum_{j=1}^{N} w_j\mathbf{u}_j$$

`margins` uses the model-based variance estimates for $(-\mathbf{H})^{-1}$ and the scores from `predict` for $\mathbf{g}(\widehat{\boldsymbol{\theta}},\mathbf{y}_j,\mathbf{x}_j)$.

Title

margins postestimation — Postestimation tools for margins

Description

The following standard postestimation command is available after `margins`:

Command	Description
`marginsplot`	graph the results from margins—profile plots, interaction plots, etc.

For information on `marginsplot`, see [R] **marginsplot**.

The following standard postestimation commands are available after `margins, post`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	estimation sample summary; `estat summarize` only
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

Remarks

Continuing with the example from *Example 8: Margins of interactions* in [R] **margins**, we use the dataset and reestimate the logistic model of `outcome`:

```
. use http://www.stata-press.com/data/r12/margex
(Artificial data for margins)
. logistic outcome sex##group age
```

(*output omitted*)

We then estimate the margins for males and females and post the margins as estimation results with a full VCE.

```
. margins sex, post
Predictive margins                                Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Delta-method					
	Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1600644	.0125653	12.74	0.000	.1354368	.184692
1	.1966902	.0100043	19.66	0.000	.1770821	.2162983

We can now use `nlcom` (see [R] **nlcom**) to estimate a risk ratio of females to males using the average probabilities for females and males posted by `margins`:

```
. nlcom (risk_ratio: _b[1.sex] / _b[0.sex])
  risk_ratio:  _b[1.sex] / _b[0.sex]
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
risk_ratio	1.228819	.1149538	10.69	0.000	1.003514	1.454124

We could similarly estimate the average risk difference between females and males:

```
. nlcom (risk_diff: _b[1.sex] - _b[0.sex])
   risk_diff:  _b[1.sex] - _b[0.sex]
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
risk_diff	.0366258	.0160632	2.28	0.023	.0051425	.068109

[R] **margins** — Marginal means, predictive margins, and marginal effects

[U] **20 Estimation and postestimation commands**

Title

margins, contrast — Contrasts of margins

Syntax

```
margins [marginlist] [if] [in] [weight] [, contrast margins_options]

margins [marginlist] [if] [in] [weight] [, contrast(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without contrast operators, and you may use any factor-variable syntax:

```
. margins sex##group, contrast
. margins sex##g.group, contrast
. margins sex@group, contrast
```

See the operators (*op.*) table in [R] **contrast** for the list of contrast operators. Contrast operators may also be specified on the variables in `margins`' `over()` and `within()` options to perform contrasts across the levels of those variables.

See [R] **margins** for the available *margins_options*.

suboptions	Description
Contrast	
`overall`	add a joint hypothesis test for all specified contrasts
`lincom`	treat user-defined contrasts as linear combinations
`atcontrast(`*op*`[ ._at ])`	apply the *op*`.` contrast operator to the groups defined by `at()`
`atjoint`	test jointly across all groups defined by `at()`
`overjoint`	test jointly across all levels of the unoperated `over()` variables
`withinjoint`	test jointly across all levels of the unoperated `within()` variables
`marginswithin`	perform contrasts within the levels of the unoperated terms in *marginlist*
`cieffects`	show effects table with confidence intervals
`pveffects`	show effects table with p-values
`effects`	show effects table with confidence intervals and p-values
`nowald`	suppress table of Wald tests
`noatlevels`	report only the overall Wald test for terms that use the within `@` or nested `|` operator
`nosvyadjust`	compute unadjusted Wald tests for survey results

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Postestimation > Contrasts of margins

Description

`margins` with the `contrast` option or with contrast operators performs contrasts of margins. This extends the capabilities of `contrast` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

Suboptions

Contrast

`overall` specifies that a joint hypothesis test over all terms be performed.

`lincom` specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

`atcontrast(`*op*`[ ._at ])` specifies that the *op*`.` contrast operator be applied to the groups defined by the `at()` option(s). The default behavior, by comparison, is to perform tests and contrasts within the groups defined by the `at()` option(s).

See example 6 in *Remarks*.

`atjoint` specifies that joint tests be performed across all groups defined by the `at()` option. The default behavior, by comparison, is to perform contrasts and tests within each group.

See example 5 in *Remarks*.

`overjoint` specifies how unoperated variables in the `over()` option are treated.

Each variable in the `over()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`overjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

See example 3 in *Remarks*.

`withinjoint` specifies how unoperated variables in the `within()` option are treated.

Each variable in the `within()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`withinjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

`marginswithin` specifies how unoperated variables in *marginlist* are treated.

Each variable in *marginlist* may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

`marginswithin` specifies that contrasts and tests be performed within each combination of levels of the unoperated variables. The default behavior, by comparison, is to perform joint tests across all levels of the unoperated variables.

See example 4 in *Remarks*.

`cieffects` specifies that a table containing a confidence interval for each individual contrast be reported.

`pveffects` specifies that a table containing a p-value for each individual contrast be reported.

`effects` specifies that a single table containing a confidence interval and p-value for each individual contrast be reported.

`nowald` suppresses the table of Wald tests.

`noatlevels` indicates that only the overall Wald test be reported for each term containing within or nested (`@` or `|`) operators.

`nosvyadjust` is for use with `svy` estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as $W/k \sim F(k,d)$ rather than as $(d-k+1)W/(kd) \sim F(k,d-k+1)$, where k is the dimension of the test and d is the total number of sampled PSUs minus the total number of strata.

Remarks

Remarks are presented under the following headings:

Contrasts of margins
Contrasts and the over() option
The overjoint suboption
The marginswithin suboption
Contrasts and the at() option
Conclusion

Contrasts of margins

▷ Example 1

Estimating contrasts of margins is as easy as adding a contrast operator to the variable name. Let's review *Example 2: A simple case after logistic* of [R] **margins**. Variable `sex` is coded `0` for males and `1` for females.

```
. use http://www.stata-press.com/data/r12/margex
. logistic outcome i.sex i.group
  (output omitted)
. margins sex
Predictive margins                              Number of obs   =       3000
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	Delta-method Margin	Std. Err.	z	P>|z|	[95% Conf.	Interval]
sex						
0	.1286796	.0111424	11.55	0.000	.106841	.1505182
1	.1905087	.0089719	21.23	0.000	.1729241	.2080933

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning `margins` and adding a contrast operator:

```
. margins r.sex
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	df	chi2	P>chi2
sex	1	16.61	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
sex				
(1 vs 0)	.0618291	.0151719	.0320927	.0915656

The `r.` prefix for `sex` is the reference-category contrast operator—see [R] **contrast**. (The default reference category is zero, the lowest value of `sex`.) Contrast operators in a *marginlist* work just as they do in the *termlist* of a `contrast` command.

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The chi-squared statistic of 16.61 shows that the contrast is significantly different from zero.

You may be surprised that we did not need to include the `contrast` option to estimate our contrast. If we had included the option, our output would not have changed:

```
. margins r.sex, contrast
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	df	chi2	P>chi2
sex	1	16.61	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
sex				
(1 vs 0)	.0618291	.0151719	.0320927	.0915656

The `contrast` option is useful mostly for its suboptions, which control the output and how contrasts are estimated in more complicated situations. But `contrast` may be specified on its own (without contrast operators or suboptions) if we do not need estimates or confidence intervals:

```
. margins sex group, contrast
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	df	chi2	P>chi2
sex	1	16.61	0.0000
group	2	225.76	0.0000

Each chi-squared statistic is a joint test of constituent contrasts. The test for group has two degrees of freedom because group has three levels.

◁

Contrasts and the over() option

▷ Example 2

It is common to estimate margins at combinations of factor levels, and margins, contrast includes several suboptions for contrasting such margins. Let's fit a model with two categorical predictors and their interaction:

```
. logistic outcome group##agegroup
Logistic regression                             Number of obs   =       3000
                                                LR chi2(8)      =     520.64
                                                Prob > chi2     =     0.0000
Log likelihood = -1105.7504                     Pseudo R2       =     0.1906
```

outcome	Odds Ratio	Std. Err.	z	P>|z|	[95% Conf.	Interval]
group						
2	.834507	.5663738	-0.27	0.790	.2206611	3.15598
3	.2146729	.1772897	-1.86	0.062	.0425407	1.083303
agegroup						
2	3.54191	2.226951	2.01	0.044	1.032882	12.14576
3	16.23351	9.61188	4.71	0.000	5.086452	51.80955
group# agegroup						
2 2	.4426927	.3358505	-1.07	0.283	.1000772	1.958257
2 3	.440672	.3049393	-1.18	0.236	.1135259	1.71055
3 2	1.160885	1.103527	0.16	0.875	.1801543	7.480553
3 3	.4407912	.4034688	-0.89	0.371	.0733	2.650709
_cons	.0379747	.0223371	-5.56	0.000	.0119897	.1202762

Each of group and agegroup has three levels. To compare each age group with the reference category on the probability scale, we can again use margins with the r. contrast operator.

```
. margins r.agegroup
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
```

	df	chi2	P>chi2
agegroup			
(2 vs 1)	1	10.04	0.0015
(3 vs 1)	1	224.44	0.0000
Joint	2	238.21	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
agegroup				
(2 vs 1)	.044498	.0140448	.0169706	.0720253
(3 vs 1)	.2059281	.0137455	.1789874	.2328688

Our model includes an interaction, though, so it would be nice to estimate the contrasts separately for each value of `group`. We need the `over()` option:

```
. margins r.agegroup, over(group)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : group
```

	df	chi2	P>chi2
agegroup@group			
(2 vs 1) 1	1	6.94	0.0084
(2 vs 1) 2	1	1.18	0.2783
(2 vs 1) 3	1	3.10	0.0783
(3 vs 1) 1	1	173.42	0.0000
(3 vs 1) 2	1	57.77	0.0000
(3 vs 1) 3	1	5.12	0.0236
Joint	6	266.84	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
agegroup@group				
(2 vs 1) 1	.0819713	.0311208	.0209757	.142967
(2 vs 1) 2	.0166206	.0153309	-.0134275	.0466686
(2 vs 1) 3	.0243462	.0138291	-.0027583	.0514508
(3 vs 1) 1	.3447797	.0261811	.2934658	.3960937
(3 vs 1) 2	.1540882	.0202722	.1143554	.193821
(3 vs 1) 3	.0470319	.0207774	.006309	.0877548

The effect of `agegroup` appears to be greatest for the first level of `group`.

Including a variable in the `over()` option is not equivalent to including the variable in the main *marginlist*. The variables in the *marginlist* are manipulated in the analysis, so that we can measure, for example, the effect of being in age group 3 and not age group 1. (The manipulation could be mimicked by running `replace` and then `predict`, but the manipulations actually performed by `margins` do not change the data in memory.) The variables in the `over()` option are not so manipulated—the values of the `over()` variables are left as they were observed, and the *marginlist* variables are manipulated separately for each observed `over()` group. For more information, see *Do not specify marginlist when you mean over()* in [R] **margins**.

◁

The overjoint suboption

▷ Example 3

Each variable in an `over()` option may be specified with or without contrast operators. Our option `over(group)` did not include a contrast operator, so `margins` estimated the contrasts separately for each level of `group`. If we had instead specified `over(r.group)`, we would have received differences of the contrasts:

```
. margins r.agegroup, over(r.group)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : group
```

	df	chi2	P>chi2
group#agegroup			
(2 vs 1) (2 vs 1)	1	3.55	0.0596
(2 vs 1) (3 vs 1)	1	33.17	0.0000
(3 vs 1) (2 vs 1)	1	2.86	0.0906
(3 vs 1) (3 vs 1)	1	79.36	0.0000
Joint	4	83.88	0.0000

	Delta-method			
	Contrast	Std. Err.	[95% Conf.	Interval]
group#agegroup				
(2 vs 1) (2 vs 1)	-.0653508	.0346921	-.133346	.0026445
(2 vs 1) (3 vs 1)	-.1906915	.0331121	-.25559	-.1257931
(3 vs 1) (2 vs 1)	-.0576251	.0340551	-.1243719	.0091216
(3 vs 1) (3 vs 1)	-.2977479	.0334237	-.3632572	-.2322385

The contrasts are double differences: the estimate of -0.19, for example, says that the difference in the probability of success between age group 3 and age group 1 is smaller in group 2 than in group 1. We can jointly test pairs of the double differences with the `overjoint` suboption:

```
. margins r.agegroup, over(group) contrast(overjoint)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : group
```

	df	chi2	P>chi2
group#agegroup			
(joint) (2 vs 1)	2	3.62	0.1641
(joint) (3 vs 1)	2	79.45	0.0000
Joint	4	83.88	0.0000

The `contrast(overjoint)` option overrides the default behavior of `over()` and requests joint tests over the levels of the unoperated variable `group`. The chi-squared statistic of 3.62 tests that the first and third contrasts from the previous table are jointly zero. The chi-squared statistic of 79.45 jointly tests the other pair of contrasts.

◁

The marginswithin suboption

▷ Example 4

Another suboption that may usefully be combined with `over()` is `marginswithin`. `marginswithin` requests that contrasts be performed within the levels of unoperated variables in the main *marginlist*, instead of performing them jointly across the levels. `marginswithin` affects only unoperated variables because contrast operators take precedence over suboptions.

Let's first look at the default behavior, which occurs when `marginswithin` is not specified:

```
. margins agegroup, over(r.group) contrast(effects)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : group
```

	df	chi2	P>chi2
group#agegroup			
(2 vs 1) (joint)	2	33.94	0.0000
(3 vs 1) (joint)	2	83.38	0.0000
Joint	4	83.88	0.0000

	Contrast	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
group# agegroup						
(2 vs 1) (2 vs base)	-.0653508	.0346921	-1.88	0.060	-.133346	.0026445
(3 vs 1) (3 vs base)	-.1906915	.0331121	-5.76	0.000	-.25559	-.1257931
(2 vs 1) (3 vs 1)	-.0576251	.0340551	-1.69	0.091	-.1243719	.0091216
(3 vs 1) (3 vs base)	-.2977479	.0334237	-8.91	0.000	-.3632572	-.2322385

Here `agegroup` in the main *marginlist* is an unoperated variable, so `margins` by default performs joint tests across the levels of `agegroup`: the chi-squared statistic of 33.94, for example, jointly tests whether the first two contrast estimates in the lower table differ significantly from zero.

When we specify marginswithin, the contrasts will instead be performed within the levels of agegroup:

```
. margins agegroup, over(r.group) contrast(marginswithin effects)
Contrasts of predictive margins
Model VCE    : OIM
Expression   : Pr(outcome), predict()
over         : group
```

	df	chi2	P>chi2
group@agegroup			
(2 vs 1) 1	1	0.06	0.7991
(2 vs 1) 2	1	7.55	0.0060
(2 vs 1) 3	1	68.39	0.0000
(3 vs 1) 1	1	1.80	0.1798
(3 vs 1) 2	1	10.47	0.0012
(3 vs 1) 3	1	159.89	0.0000
Joint	6	186.87	0.0000

	Contrast	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
group@ agegroup						
(2 vs 1) 1	-.0058686	.0230533	-0.25	0.799	-.0510523	.039315
(2 vs 1) 2	-.0712194	.0259246	-2.75	0.006	-.1220308	-.0204081
(2 vs 1) 3	-.1965602	.0237688	-8.27	0.000	-.2431461	-.1499742
(3 vs 1) 1	-.0284991	.0212476	-1.34	0.180	-.0701436	.0131453
(3 vs 1) 2	-.0861243	.0266137	-3.24	0.001	-.1382862	-.0339624
(3 vs 1) 3	-.326247	.0258009	-12.64	0.000	-.3768159	-.2756781

The joint tests in the top table have been replaced by one-degree-of-freedom tests, one for each combination of the two reference comparisons and three levels of agegroup. The reference-category contrasts for group have been performed within levels of agegroup.

◁

Contrasts and the at() option

▷ Example 5

The at() option of margins is used to set predictors to particular values. When at() is used, contrasts are by default performed within each at() level:

```
. margins r.agegroup, at(group=(1/3))
Contrasts of adjusted predictions
Model VCE    : OIM
Expression   : Pr(outcome), predict()
1._at        : group           =           1
2._at        : group           =           2
3._at        : group           =           3
```

	df	chi2	P>chi2
agegroup@_at			
(2 vs 1) 1	1	6.94	0.0084
(2 vs 1) 2	1	1.18	0.2783
(2 vs 1) 3	1	3.10	0.0783
(3 vs 1) 1	1	173.42	0.0000
(3 vs 1) 2	1	57.77	0.0000
(3 vs 1) 3	1	5.12	0.0236
Joint	6	266.84	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
agegroup@_at				
(2 vs 1) 1	.0819713	.0311208	.0209757	.142967
(2 vs 1) 2	.0166206	.0153309	-.0134275	.0466686
(2 vs 1) 3	.0243462	.0138291	-.0027583	.0514508
(3 vs 1) 1	.3447797	.0261811	.2934658	.3960937
(3 vs 1) 2	.1540882	.0202722	.1143554	.193821
(3 vs 1) 3	.0470319	.0207774	.006309	.0877548

Our option `at(group=(1/3))` manipulates the values of `group` and is therefore not equivalent to `over(group)`. We see that the reference-category contrasts for `agegroup` have been performed within each `at()` level. For a similar example that uses the `._at` operator instead of the `at()` option, see *Contrasts of at() groups—discrete effects* in [R] **marginsplot**.

The default within behavior of `at()` may be changed to joint behavior with the `atjoint` suboption:

```
. margins r.agegroup, at(group=(1/3)) contrast(atjoint)
Contrasts of adjusted predictions
Model VCE    : OIM
Expression   : Pr(outcome), predict()
1._at        : group           =           1
2._at        : group           =           2
3._at        : group           =           3
```

	df	chi2	P>chi2
_at#agegroup			
(joint) (2 vs 1)	2	3.62	0.1641
(joint) (3 vs 1)	2	79.45	0.0000
Joint	4	83.88	0.0000

Now the tests are performed jointly over the levels of `group`, the `at()` variable. The `atjoint` suboption is the analogue for `at()` of the `overjoint` suboption from example 3.

◁

▷ Example 6

What if we would like to apply a contrast operator, like `r.`, to the `at()` levels? It is not possible to specify the operator inside the `at()` option. Instead, we need a new suboption, `atcontrast()`:

```
. margins r.agegroup, at(group=(1/3)) contrast(atcontrast(r))
Contrasts of adjusted predictions
Model VCE    : OIM
Expression   : Pr(outcome), predict()
1._at        : group           =           1
2._at        : group           =           2
3._at        : group           =           3
```

	df	chi2	P>chi2
_at#agegroup			
(2 vs 1) (2 vs 1)	1	3.55	0.0596
(2 vs 1) (3 vs 1)	1	33.17	0.0000
(3 vs 1) (2 vs 1)	1	2.86	0.0906
(3 vs 1) (3 vs 1)	1	79.36	0.0000
Joint	4	83.88	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
_at#agegroup				
(2 vs 1) (2 vs 1)	-.0653508	.0346921	-.133346	.0026445
(2 vs 1) (3 vs 1)	-.1906915	.0331121	-.25559	-.1257931
(3 vs 1) (2 vs 1)	-.0576251	.0340551	-.1243719	.0091216
(3 vs 1) (3 vs 1)	-.2977479	.0334237	-.3632572	-.2322385

When we specify `contrast(atcontrast(r))`, `margins` will apply the `r.` reference-category operator to the levels of `group`, the variable specified inside `at()`. The default reference category is `1`, the lowest level of `group`.

Conclusion

`margins, contrast` is a powerful command, and its abundance of suboptions may seem daunting. The suboptions are in the service of only three goals, however. There are three things that `margins, contrast` can do with a factor variable or a set of `at()` definitions:

1. Perform contrasts across the levels of the factor or set (as in example 1).
2. Perform a joint test across the levels of the factor or set (as in example 5).
3. Perform other tests and contrasts within each level of the factor or set (as in example 4).

The default behavior for variables specified inside `at()`, `over()`, and `within()` is to perform contrasts within groups; the default behavior for variables in the *marginlist* is to perform joint tests across groups.

◁

Saved results

`margins, contrast` saves the following additional items in `r()`:

Scalars
- `r(k_terms)` — number of terms participating in contrasts

Macros
- `r(cmd)` — `contrast`
- `r(cmd2)` — `margins`
- `r(overall)` — `overall` or empty

Matrices
- `r(L)` — matrix of contrasts applied to the margins
- `r(chi2)` — vector of χ^2 statistics
- `r(p)` — vector of p-values corresponding to `r(chi2)`
- `r(df)` — vector of degrees of freedom corresponding to `r(p)`

`margins, contrast` with the `post` option also saves the following additional items in `e()`:

Scalars
- `e(k_terms)` — number of terms participating in contrasts

Macros
- `e(cmd)` — `contrast`
- `e(cmd2)` — `margins`
- `e(overall)` — `overall` or empty

Matrices
- `e(L)` — matrix of contrasts applied to the margins
- `e(chi2)` — vector of χ^2 statistics
- `e(p)` — vector of p-values corresponding to `e(chi2)`
- `e(df)` — vector of degrees of freedom corresponding to `e(p)`

Title

margins, pwcompare — Pairwise comparisons of margins

Syntax

```
margins [marginlist] [if] [in] [weight] [, pwcompare margins_options]

margins [marginlist] [if] [in] [weight] [, pwcompare(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

```
. margins i.sex i.group i.sex#i.group, pwcompare
. margins sex group sex#i.group, pwcompare
. margins sex##group, pwcompare
```

See [R] **margins** for the available *margins_options*.

suboptions	Description
Pairwise comparisons	
`cieffects`	show effects table with confidence intervals; the default
`pveffects`	show effects table with p-values
`effects`	show effects table with confidence intervals and p-values
`cimargins`	show table of margins and confidence intervals
`groups`	show table of margins and group codes
`sort`	sort the margins or contrasts in each term

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Postestimation > Pairwise comparisons of margins

Description

`margins` with the `pwcompare` option performs pairwise comparisons of margins. `margins, pwcompare` extends the capabilities of `pwcompare` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

Suboptions

Pairwise comparisons

`cieffects` specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, and p-values be reported.

`effects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, p-values, and confidence intervals be reported.

`cimargins` specifies that a table of the margins with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted on the margins or contrasts in each term.

Remarks

You should be familiar with the concepts and syntax of both `margins` and `pwcompare` before using the `pwcompare` option of `margins`. These remarks build on those in [R] **margins** and [R] **pwcompare**.

`margins` can perform pairwise comparisons of any of the margins that it estimates.

In the *Continuous covariates* example in [R] **marginsplot**, we fit a logistic regression model using the NHANES II dataset, ignoring the complex survey nature of the data. Our dependent variable is `highbp`, an indicator for whether a person has high blood pressure. We fit a fully interacted model including two factor variables representing gender and age group as well as the continuous covariate, `bmi`.

```
. use http://www.stata-press.com/data/r12/nhanes2
. logistic highbp sex##agegrp##c.bmi
  (output omitted)
```

By default, `margins` will compute the predictive margins of the probability of a positive outcome for each of the terms in *marginlist* after logistic regression. We will margin on `agegrp` so that `margins` will estimate the average predicted probabilities of having high blood pressure conditional on being in each of the six age groups and unconditional on sex and BMI. We can specify the `pwcompare` option to obtain all possible pairwise comparisons of these predictive margins:

```
. margins agegrp, pwcompare
Pairwise comparisons of predictive margins
Model VCE    : OIM
Expression   : Pr(highbp), predict()
```

	Contrast	Delta-method Std. Err.	Unadjusted [95% Conf.	Interval]
agegrp				
2 vs 1	.0182344	.0069751	.0045635	.0319054
3 vs 1	.08395	.0097271	.0648852	.1030148
4 vs 1	.1443977	.0111944	.122457	.1663383
5 vs 1	.1517272	.0082323	.1355922	.1678622
6 vs 1	.1443064	.0126661	.1194813	.1691314
3 vs 2	.0657156	.010205	.0457141	.0857171
4 vs 2	.1261632	.0116121	.1034039	.1489225
5 vs 2	.1334928	.0087919	.116261	.1507245
6 vs 2	.1260719	.0130367	.1005205	.1516234
4 vs 3	.0604477	.0134464	.0340932	.0868021
5 vs 3	.0677772	.0111023	.046017	.0895374
6 vs 3	.0603564	.0146942	.0315562	.0891565
5 vs 4	.0073296	.012408	-.0169898	.0316489
6 vs 4	-.0000913	.0157041	-.0308707	.0306882
6 vs 5	-.0074208	.0137504	-.0343712	.0195295

This table gives each of the pairwise differences with confidence intervals. We can see that the confidence interval in the row labeled `(2 vs 1)` does not include zero. At the 5% level, the predictive margins for the first and second age groups are significantly different. The same is true of many of the other comparisons. With many pairwise comparisons, output in this format can be difficult to sort through. We can put some structure on this by adding the `group` suboption:

```
. margins agegrp, pwcompare(group)
Pairwise comparisons of predictive margins
Model VCE    : OIM
Expression   : Pr(highbp), predict()
```

	Margin	Delta-method Std. Err.	Unadjusted Groups
agegrp			
1	.0375314	.004423	
2	.0557658	.0053934	
3	.1214814	.0086634	
4	.181929	.0102836	A
5	.1892586	.0069432	A
6	.1818377	.0118687	A

```
Note: Margins sharing a letter in the group label
      are not significantly different at the 5%
      level.
```

The group output includes the predictive margins for each age group and letters denoting margins that are not significantly different from each other. In this case, there is not a letter associated with the first age group in the "Unadjusted Groups" column. This missingness indicates that the average predicted probability for this age group is significantly different from the average predicted probability for each of the other age groups at the 5% significance level. The absence of a letter next to the second and third age groups is interpreted in a similar manner. The fourth, fifth, and sixth age groups each

have an A in the "Unadjusted Groups" column, which indicates that the average predicted probabilities for these groups are not significantly different at our 5% level.

We can also include the mcompare(bonferroni) option to perform tests using Bonferroni's method to account for making multiple comparisons.

```
. margins agegrp, pwcompare(group) mcompare(bonferroni)
Pairwise comparisons of predictive margins
Model VCE    : OIM
Expression   : Pr(highbp), predict()
```

	Number of Comparisons
agegrp	15

	Margin	Delta-method Std. Err.	Bonferroni Groups
agegrp			
1	.0375314	.004423	B
2	.0557658	.0053934	B
3	.1214814	.0086634	
4	.181929	.0102836	A
5	.1892586	.0069432	A
6	.1818377	.0118687	A

```
Note: Margins sharing a letter in the group label
      are not significantly different at the 5%
      level.
```

We now see the letter B on the rows corresponding to the first and second age groups. At the 5% level and using Bonferroni's adjustment, the predictive margins for the probability in the first and second age groups are not significantly different.

Saved results

margins, pwcompare saves the following additional items in r():

Scalars

r(k_terms)	number of terms participating in pairwise comparisons

Macros

r(cmd)	pwcompare
r(cmd2)	margins
r(group#)	group code for the #th margin in r(b)
r(mcmethod_vs)	*method* from mcompare()
r(mctitle_vs)	title for *method* from mcompare()
r(mcadjustall_vs)	adjustall or empty

Matrices

r(b)	margin estimates
r(V)	variance–covariance matrix of the margin estimates
r(b_vs)	margin difference estimates
r(V_vs)	variance–covariance margin difference of the margin estimates
r(error_vs)	margin difference estimability codes; 0 means estimable, 8 means not estimable
r(table_vs)	matrix containing the margin differences with their standard errors, test statistics, p-values, and confidence intervals
r(L)	matrix that produces the margin differences

`margins, pwcompare` with the `post` option also saves the following additional items in `e()`:

Scalars	
`e(k_terms)`	number of terms participating in pairwise comparisons
Macros	
`e(cmd)`	`pwcompare`
`e(cmd2)`	`margins`
Matrices	
`e(b)`	margin estimates
`e(V)`	variance–covariance matrix of the margin estimates
`e(b_vs)`	margin difference estimates
`e(V_vs)`	variance–covariance margin difference of the margin estimates
`e(error_vs)`	margin difference estimability codes; `0` means estimable, `8` means not estimable
`e(L)`	matrix that produces the margin differences

Title

marginsplot — Graph results from margins (profile plots, etc.)

Syntax

```
marginsplot [ , options ]
```

options	Description
Main	
`xdimension(`*dimlist* `[ , `*dimopts*`])`	use *dimlist* to define x axis
`plotdimension(`*dimlist* `[ , `*dimopts*`])`	create plots for groups in *dimlist*
`bydimension(`*dimlist* `[ , `*dimopts*`])`	create subgraphs for groups in *dimlist*
`graphdimension(`*dimlist* `[ , `*dimopts*`])`	create graphs for groups in *dimlist*
`horizontal`	swap x and y axes
`noci`	do not plot confidence intervals
`name(`*name* | *stub* `[ , replace ])`	name of graph, or stub if multiple graphs
Labels	
`allxlabels`	place ticks and labels on the x axis for each value
`nolabels`	label groups with their values, not their labels
`allsimplelabels`	forgo variable name and equal signs in all labels
`nosimplelabels`	include variable name and equal signs in all labels
`separator(`*string*`)`	separator for labels when multiple variables are specified in a dimension
`noseparator`	do not use a separator
Plot	
`plotopts(`*plot_options*`)`	affect rendition of all margin plots
`plot#opts(`*plot_options*`)`	affect rendition of #th margin plot
`recast(`*plottype*`)`	plot margins using *plottype*
CI plot	
`ciopts(`*rcap_options*`)`	affect rendition of all confidence-interval plots
`ci#opts(`*rcap_options*`)`	affect rendition of #th confidence-interval plot
`recastci(`*plottype*`)`	plot confidence intervals using *plottype*
Pairwise	
`unique`	plot only unique pairwise comparisons
`csort`	sort comparison categories first
Add plots	
`addplot(`*plot*`)`	add other plots to the graph
Y axis, X axis, Titles, Legend, Overall, By	
twoway_options	any options documented in [G-3] ***twoway_options***
`byopts(`*byopts*`)`	how subgraphs are combined, labeled, etc.

where *dimlist* may be any of the dimensions across which margins were computed in the immediately preceding `margins` command; see [R] **margins**. That is to say, *dimlist* may be any variable used in the `margins` command, including variables specified in the `at()`, `over()`, and `within()` options. More advanced specifications of *dimlist* are covered in *Addendum: Advanced uses of dimlist*.

dimopts	Description
`labels(`*lablist*`)`	list of quoted strings to label each level of the dimension
`elabels(`*elablist*`)`	list of enumerated labels
`nolabels`	label groups with their values, not their labels
`allsimplelabels`	forgo variable name and equal signs in all labels
`nosimplelabels`	include variable name and equal signs in all labels
`separator(`*string*`)`	separator for labels when multiple variables are specified in the dimension
`noseparator`	do not use a separator

where *lablist* is defined as

"label" [*"label"* [...]]

elablist is defined as

 # "label" [*# "label"* [...]]

and the #s are the indices of the levels of the dimension—1 is the first level, 2 is the second level, and so on.

plot_options	Description
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
cline_options	change look of the line

Menu

Statistics > Postestimation > Margins plots and profile plots

Description

`marginsplot` graphs the results of the immediately preceding `margins` command; see [R] **margins**. Common names for some of the graphs that `marginsplot` can produce are profile plots and interaction plots.

Options

Main

`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()` specify the variables from the preceding `margins` command whose group levels will be used for the graph's x axis, plots, `by()` subgraphs, and graphs.

marginsplot chooses default dimensions based on the margins command. In most cases, the first variable appearing in an at() option and evaluated over more than one value is used for the x axis. If no at() variable meets this condition, the first variable in the *marginlist* is usually used for the x axis and the remaining variables determine the plotted lines or markers. Pairwise comparisons and graphs of marginal effects (derivatives) have different defaults. In all cases, you may override the defaults and explicitly control which variables are used on each dimension of the graph by using these dimension options.

Each of these options supports suboptions that control the labeling of the dimension—axis labels for xdimension(), plot labels for plotdimension(), subgraph titles for bydimension(), and graph titles for graphdimension() titles.

For examples using the dimension options, see *Controlling the graph's dimensions*.

xdimension(*dimlist* [, *dimopts*]) specifies the variables for the x axis in *dimlist* and controls the content of those labels with *dimopts*.

plotdimension(*dimlist* [, *dimopts*]) specifies in *dimlist* the variables whose group levels determine the plots and optionally specifies in *dimopts* the content of the plots' labels.

bydimension(*dimlist* [, *dimopts*]) specifies in *dimlist* the variables whose group levels determine the by() subgraphs and optionally specifies in *dimopts* the content of the subgraphs' titles. For an example using by(), see *Three-way interactions*.

graphdimension(*dimlist* [, *dimopts*]) specifies in *dimlist* the variables whose group levels determine the graphs and optionally specifies in *dimopts* the content of the graphs' titles.

horizontal reverses the default x and y axes. By default, the y axis represents the estimates of the margins and the x axis represents one or more factors or continuous covariates. Specifying horizontal swaps the axes so that the x axis represents the estimates of the margins. This option can be useful if the labels on the factor or continuous covariates are long.

The horizontal option is discussed in *Horizontal is sometimes better*.

noci removes plots of the pointwise confidence intervals. The default is to plot the confidence intervals.

name(*name* | *stub* [, replace]) specifies the name of the graph or graphs. If the graphdimension() option is specified, or if the default action is to produce multiple graphs, then the argument of name() is taken to be *stub* and graphs named *stub*1, *stub*2, ... are created.

The replace suboption causes existing graphs with the specified name or names to be replaced.

If name() is not specified, default names are used and the graphs may be replaced by subsequent marginsplot or other graphing commands.

Labels

With the exception of allxlabels, all these options may be specified either directly as options or as *dimopts* within options xdimension(), plotdimension(), bydimension(), and graphdimension(). When specified in one of the dimension options, only the labels for that dimension are affected. When specified outside the dimension options, all labels on all dimensions are affected. Specifications within the dimension options take precedence.

allxlabels specifies that tick marks and labels be placed on the x axis for each value of the x-dimension variables. By default, if there are more than 25 ticks, default graph axis labeling rules are applied. Labeling may also be specified using the standard graph twoway x-axis label rules and options—xlabel(); see [G-3] ***axis_label_options***.

`nolabels` specifies that value labels not be used to construct graph labels and titles for the group levels in the dimension. By default, if a variable in a dimension has value labels, those labels are used to construct labels and titles for axis ticks, plots, subgraphs, and graphs.

Graphs of contrasts and pairwise comparisons are an exception to this rule and are always labeled with values rather than value labels.

`allsimplelabels` and `nosimplelabels` control whether graphs' labels and titles include just the values of the variables or include variable names and equal signs. The default is to use just the value label for variables that have value labels and to use variable names and equal signs for variables that do not have value labels. An example of the former is "Female" and the latter is "country=2".

Sometimes value labels are universally descriptive, and sometimes they have meaning only when considered in relation to their variable. For example, "Male" and "Female" are typically universal, regardless of the variable from which they are taken. "High" and "Low" may not have meaning unless you know they are in relation to a specific measure, say, blood-pressure level. The `allsimplelabels` and `nosimplelabels` options let you override the default labeling.

`allsimplelabels` specifies that all titles and labels use just the value or value label of the variable.

`nosimplelabels` specifies that all titles and labels include *varname*`=` before the value or value label of the variable.

`separator(`*string*`)` and `noseparator` control the separator between label sections when more than one variable is used to specify a dimension. The default separator is a comma followed by a space, but no separator may be requested with `noseparator` or the default may be changed to any string with `separator()`.

For example, if `plotdimension(a b)` is specified, the plot labels in our graph legend might be "a=1, b=1", "a=1, b=2", ... Specifying `separator(:)` would create labels "a=1:b=1", "a=1:b=2", ...

Plot

`plotopts(`*plot_options*`)` affects the rendition of all margin plots. The *plot_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] ***marker_options***, [G-3] ***marker_label_options***, and [G-3] ***cline_options***.

These settings may be overridden for specific plots by using the `plot#opts()` option.

`plot#opts(`*plot_options*`)` affects the rendition of the #th margin plot. The *plot_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] ***marker_options***, [G-3] ***marker_label_options***, and [G-3] ***cline_options***.

`recast(`*plottype*`)` specifies that margins be plotted using *plottype*. *plottype* may be `scatter`, `line`, `connected`, `bar`, `area`, `spike`, `dropline`, or `dot`; see [G-2] **graph twoway**. When `recast()` is specified, the plot-rendition options appropriate to the specified *plottype* may be used in lieu of *plot_options*. For details on those options, follow the appropriate link from [G-2] **graph twoway**.

For an example using `recast()`, see *Continuous covariates*.

You may specify `recast()` within a `plotopts()` or `plot#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified *plottype*.

CI plot

`ciopts(`*rcap_options*`)` affects the rendition of all confidence-interval plots; see [G-3] ***rcap_options***.

These settings may be overridden for specific confidence-interval plots with the `ci#opts()` option.

`ci#opts(`*rcap_options*`)` affects the rendition of the #th confidence interval; see [G-3] ***rcap_options***.

`recastci(`*plottype*`)` specifies that confidence intervals be plotted using *plottype*. *plottype* may be `rarea`, `rbar`, `rspike`, `rcap`, `rcapsym`, `rline`, `rconnected`, or `rscatter`; see [G-2] **graph twoway**. When `recastci()` is specified, the plot-rendition options appropriate to the specified *plottype* may be used in lieu of *rcap_options*. For details on those options, follow the appropriate link from [G-2] **graph twoway**.

For an example using `recastci()`, see *Continuous covariates*.

You may specify `recastci()` within a `ciopts()` or `ci#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified *plottype*.

Pairwise

These options have an effect only when the `pwcompare` option was specified on the preceding `margins` command.

`unique` specifies that only unique pairwise comparisons be plotted. The default is to plot all pairwise comparisons, including those that are mirror images of each other—"male" versus "female" and "female" versus "male". `margins` reports only the unique pairwise comparisons. `unique` also changes the default `xdimension()` for graphs of pairwise comparisons from the reference categories (`_pw0`) to the comparisons of each pairwise category (`_pw`).

Unique comparisons are often preferred with horizontal graphs that put all pairwise comparisons on the x axis, whereas including the full matrix of comparisons is preferred for charts showing the reference groups on an axis and the comparison groups as plots; see *Pairwise comparisons* and *Horizontal is sometimes better*.

`csort` specifies that comparison categories are sorted first, and then reference categories are sorted within comparison category. The default is to sort reference categories first, and then sort comparison categories within reference categories. This option has an observable effect only when `_pw` is also specified in one of the dimension options. It then determines the order of the labeling in the dimension where `_pw` is specified.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph; see [G-3] ***addplot_option***.

For an example using `addplot()`, see *Adding scatterplots of the data*.

If multiple graphs are drawn by a single `marginsplot` command or if *plot* specifies plots with multiple y variables, for example, `scatter y1 y2 x`, then the graph's legend will not clearly identify all the plots and will require customization using the `legend()` option; see [G-3] ***legend_options***.

Y axis, X axis, Titles, Legend, Overall, By

twoway_options are any of the options documented in [G-3] ***twoway_options***. These include options for titling the graph (see [G-3] ***title_options***); for saving the graph to disk (see [G-3] ***saving_option***); for controlling the labeling and look of the axes (see [G-3] ***axis_options***); for controlling the look, contents, position, and organization of the legend (see [G-3] ***legend_options***); for adding lines (see [G-3] ***added_line_options***) and text (see [G-3] ***added_text_options***); and for controlling other aspects of the graph's appearance (see [G-3] ***twoway_options***).

The `label()` suboption of the `legend()` option has no effect on `marginsplot`. Use the `order()` suboption instead.

`byopts(`*byopts*`)` affects the appearance of the combined graph when `bydimension()` is specified or when the default graph has subgraphs, including the overall graph title, the position of the legend, and the organization of subgraphs. See [G-3] ***by_option***.

Remarks

Remarks are presented under the following headings:

Introduction
Dataset
Profile plots
Interaction plots
Contrasts of margins—effects (discrete marginal effects)
Three-way interactions
Continuous covariates
Plots at every value of a continuous covariate
Contrasts of at() groups—discrete effects
Controlling the graph's dimensions
Pairwise comparisons
Horizontal is sometimes better
Marginal effects
Plotting a subset of the results from margins
Advanced usage
Plots with multiple terms
Plots with multiple at() options
Adding scatterplots of the data

Introduction

`marginsplot` is a post-`margins` command. It graphs the results of the `margins` command, whether those results are marginal means, predictive margins, marginal effects, contrasts, pairwise comparisons, or other statistics; see [R] **margins**.

By default, the margins are plotted on the y axis, and all continuous and factor covariates specified in the `margins` command will usually be placed on the x axis or used to identify plots. Exceptions are discussed in the following sections and in *Addendum: Advanced uses of dimlist* below.

`marginsplot` produces classic plots, such as profile plots and interaction plots. Beyond that, anything that `margins` can compute, `marginsplot` can graph.

We will be using some relatively complicated `margins` commands with little explanation of the syntax. We will also avoid lengthy interpretations of the results of margins. See [R] **margins** for the complete syntax of `margins` and discussions of its results.

All graphs in this entry were drawn using the `s2gmanual` scheme; see [G-4] **scheme s2**.

Dataset

For continuity, we will use one dataset for most examples—the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). NHANES II is part of a study to assess the health and nutritional status of adults and children in the United States. It is designed to be a nationally representative sample of the U.S. population. This particular sample is from 1976 to 1980.

The survey nature of the dataset—weights, strata, and sampling units—will be ignored in our analyses. We are discussing graphing, not survey statistics. If you would like to see the results with the appropriate adjustments for the survey design, just add `svy:` before each estimation command, and if you wish, add `vce(unconditional)` as an option to each `margins` command. See [R] **margins**, particularly the discussion and examples under *Obtaining margins with survey data and representative samples*, for reasons why you probably would want to add `vce(unconditional)` when analyzing survey data. For the most part, adjusting for survey design produces moderately larger confidence intervals and relatively small changes in point estimates.

Profile plots

What does my estimation say about how my response varies as one (or more) of my covariates changes? That is the question that is answered by profile plots. Profile plots are also referred to as plots of estimated (or expected, or least-squares) means, though that is unnecessarily restrictive when considering models of binary, count, and ordered outcomes. In the latter cases, we might prefer to say they plot conditional expectations of responses, where a response might be a probability.

What we do with the other covariates depends on the questions we wish to answer. Sometimes we wish to hold other covariates at fixed values, and sometimes we wish to average the response over their values. `margins` can do either, so you can graph either.

We can fit a fully factorial two-way ANOVA of systolic blood pressure on age group and sex using the NHANES II data.

```
. use http://www.stata-press.com/data/r12/nhanes2
. anova bpsystol agegrp##sex
```

```
                   Number of obs =   10351     R-squared     =  0.2497
                   Root MSE      = 20.2209     Adj R-squared =  0.2489

      Source |  Partial SS    df       MS           F     Prob > F
-------------+----------------------------------------------------
       Model |  1407229.28    11  127929.935     312.88     0.0000

      agegrp |  1243037.82     5  248607.565     608.02     0.0000
         sex |  27728.3794     1  27728.3794      67.81     0.0000
agegrp#sex |   88675.043     5  17735.0086      43.37     0.0000

    Residual |  4227440.75 10339  408.882943
-------------+----------------------------------------------------
       Total |  5634670.03 10350  544.412563
```

If you are more comfortable with regression than ANOVA, then type

```
. regress bpsystol agegrp##sex
```

The `anova` and `regress` commands fit identical models. The output from `anova` displays all the terms in the model and thus tends to be more conducive to exploration with `margins` and `marginsplot`.

We estimate the predictive margins of systolic blood pressure for each age group using `margins`.

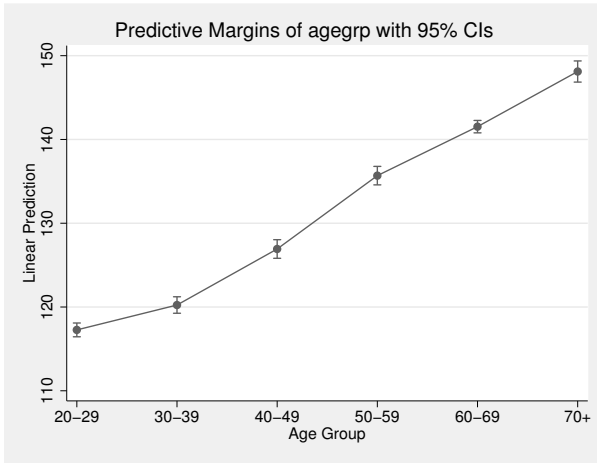
```
. margins agegrp
Predictive margins                              Number of obs   =      10351
Expression   : Linear prediction, predict()
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
agegrp						
1	117.2684	.419845	279.31	0.000	116.4455	118.0913
2	120.2383	.5020813	239.48	0.000	119.2542	121.2224
3	126.9255	.56699	223.86	0.000	125.8142	128.0368
4	135.682	.5628593	241.06	0.000	134.5788	136.7852
5	141.5285	.3781197	374.30	0.000	140.7874	142.2696
6	148.1096	.6445073	229.80	0.000	146.8464	149.3728

The six predictive margins are just the averages of the predictions over the estimation sample, holding `agegrp` to each of its six levels. If this were a designed experiment rather than survey data, we might wish to assume the cells are balanced—that they have the same number of observations—and thus estimate what are often called expected means or least-squares means. To do that, we would simply add the `asbalanced` option to the `margins` command. The NHANES II data are decidedly unbalanced over `sex#agegrp` cells. So much so that it is unreasonable to assume the cells are balanced.

We graph the results:

```
. marginsplot
```



Profile plots are often drawn without confidence intervals (CIs). The CIs may be removed by adding the `noci` option. We prefer to see the CIs.

Disciplines vary widely in their use of the term profile plot. Some disciplines consider any connected plot of a response over values of other variables to be a profile plot. By that definition, most graphs in this entry are profile plots.

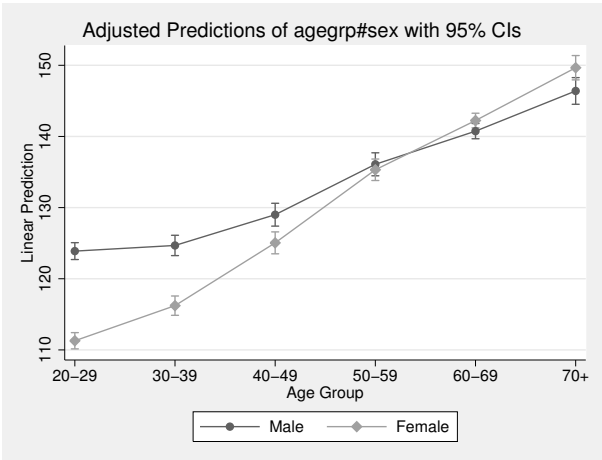
Interaction plots

Interaction plots are often used to explore the form of an interaction. The interaction term in our ANOVA results is highly significant. Are the interaction effects also large enough to matter? What form do they take? We can answer these questions by fixing `agegrp` and `sex` to each possible combination of the two covariates and estimating the margins for those cells.

```
. margins agegrp#sex
```

Then we can graph the results:

```
. marginsplot
```



It is clear that the effect of age differs by sex—there is an interaction. If there were no interaction, then the two lines would be parallel.

While males start out with higher systolic blood pressure, females catch up to the males as age increases and may even surpass males in the upper age groups. We say "may" because we cannot tell if the differences are statistically significant. The CIs overlap for the top three age groups. It is tempting to conclude from this overlap that the differences are not statistically significant. Do not fall into this trap. Likewise, do not fall into the trap that the first three age groups are different because their CIs do not overlap. The CIs are for the point estimates, not the differences. There is a covariance between the differences that we must consider if we are to make statements about those differences.

Contrasts of margins—effects (discrete marginal effects)

To assess the differences, all we need do is ask `margins` to contrast the sets of effects that we just estimated; see [R] **margins, contrast**. With only two groups in sex, it does not matter much which contrast operator we choose. We will use the reference contrast. It will compare the difference between males and females, with males (the first category) as the reference category.

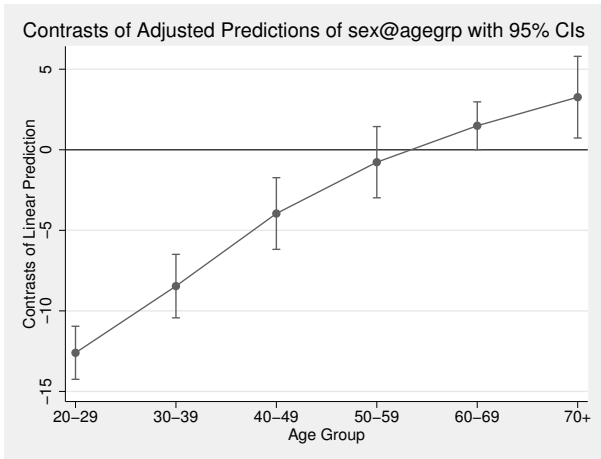
```
. margins r.sex@agegrp
Contrasts of adjusted predictions
Expression   : Linear prediction, predict()
```

	df	chi2	P>chi2
sex@agegrp			
(2 vs 1) 1	1	224.92	0.0000
(2 vs 1) 2	1	70.82	0.0000
(2 vs 1) 3	1	12.15	0.0005
(2 vs 1) 4	1	0.47	0.4949
(2 vs 1) 5	1	3.88	0.0488
(2 vs 1) 6	1	6.37	0.0116
Joint	6	318.62	0.0000

	Contrast	Delta-method Std. Err.	[95% Conf.	Interval]
sex@agegrp				
(2 vs 1) 1	-12.60132	.8402299	-14.24814	-10.9545
(2 vs 1) 2	-8.461161	1.005448	-10.4318	-6.490518
(2 vs 1) 3	-3.956451	1.134878	-6.180771	-1.732131
(2 vs 1) 4	-.7699782	1.128119	-2.98105	1.441094
(2 vs 1) 5	1.491684	.756906	.0081759	2.975193
(2 vs 1) 6	3.264762	1.293325	.7298908	5.799633

Because we are looking for effects that are different from 0, we will add a reference line at 0 to our graph.

```
. marginsplot, yline(0)
```



We can now say that females' systolic blood pressure is substantially and significantly lower than males' in the first three age groups but is significantly higher in the last two age groups. Despite the overlapping CIs for the last two age groups in the interaction graph, the effect of sex is significant in these age groups.

The terminology for what we just estimated and graphed varies widely across disciplines. Those versed in design of experiments refer to these values as contrasts or effects. Economists and some other

social scientists call them marginal or partial effects. The latter groups might be more comfortable if we avoided the whole concept of contrasts and instead estimated the effects by typing

```
. margins agegrp, dydx(sex)
```

This will produce estimates that are identical to those shown above, and we can graph them by typing `marginsplot`.

The advantage of using the contrast notation and thinking in contrasts is most evident when we take marginal effects with respect to a categorical covariate with more than two levels. Marginal effects for each level of the covariate will be taken with respect to a specified base level. Contrasts are much more flexible. Using the `r.` operator, we can reproduce the marginal-effects results by taking derivatives with respect to a reference level (as we saw above.) We can also estimate the marginal effect of first moving from level 1 to level 2, then from level 2 to level 3, then from level 3 to level 4, ... using the `ar.` or "reverse adjacent" operator. Adjacent effects (marginal effects) can be valuable when evaluating an ordinal covariate, such as `agegrp` in our current model. For a discussion of contrasts, see [R] **contrast** and [R] **margins, contrast**.

Three-way interactions

`marginsplot` can handle any number of covariates in your `margins` command. Consider the three-way ANOVA model that results from adding an indicator for whether an individual has been diagnosed with diabetes. We will fully interact the new covariate with the others in the model.

```
. anova bpsystol agegrp##sex##diabetes
                          Number of obs =   10349     R-squared     =  0.2572
                          Root MSE      =  20.131     Adj R-squared =  0.2556
```

Source	Partial SS	df	MS	F	Prob > F
Model	1448983.17	23	62999.2681	155.45	0.0000
agegrp	107963.582	5	21592.7164	53.28	0.0000
sex	1232.79267	1	1232.79267	3.04	0.0812
agegrp#sex	11679.5925	5	2335.91849	5.76	0.0000
diabetes	7324.98924	1	7324.98924	18.07	0.0000
agegrp#diabetes	5484.54623	5	1096.90925	2.71	0.0189
sex#diabetes	102.988239	1	102.988239	0.25	0.6142
agegrp#sex#diabetes	4863.14971	5	972.629943	2.40	0.0349
Residual	4184296.88	10325	405.258778		
Total	5633280.05	10348	544.38346		

The three-way interaction is significant, as is the main effect of `diabetes` and its interaction with `agegrp`.

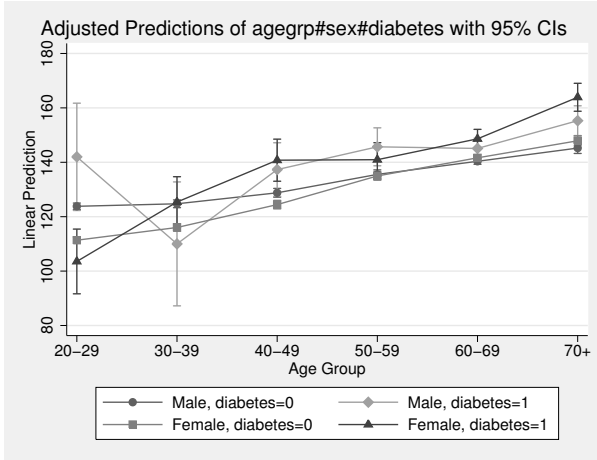
Again, if you are more comfortable with regression than ANOVA, you may type

```
. regress bpsystol agegrp##sex##diabetes
```

The `margins` and `marginsplot` results will be the same.

We estimate the expected cell means for each combination of `agegrp`, `sex`, and `diabetes`, and then graph the results by typing

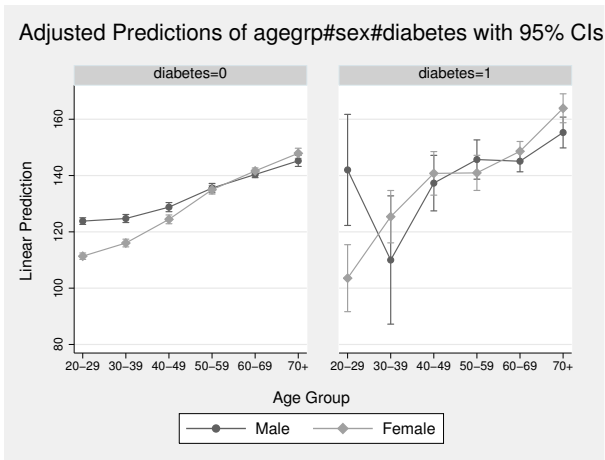
```
. margins agegrp#sex#diabetes
(output omitted)
. marginsplot
```



The graph is busy and difficult to interpret.

We can make it better by putting those with diabetes on one subgraph and those without on another:

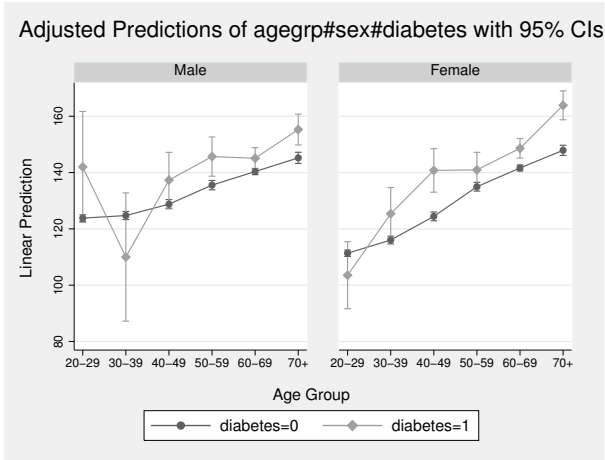
```
. marginsplot, by(diabetes)
```



We notice much larger CIs for diabetics. That is not surprising because our sample contains only 499 diabetics compared with 9,850 nondiabetics.

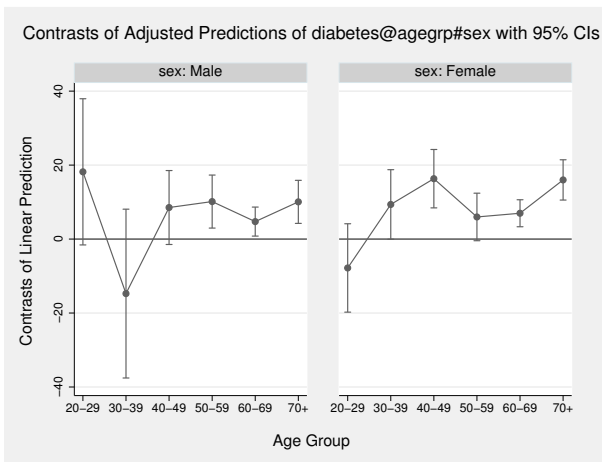
A more interesting way to arrange the plots is by grouping the subgraphs on `sex`:

```
. marginsplot, by(sex)
```



Aside from increased systolic blood pressure in the upper-age groups, which we saw earlier, it appears that those with diabetes are at greater risk of higher systolic blood pressure for many upper-age groups. We can check that by having `margins` estimate the differences between diabetics and nondiabetics, and graphing the results.

```
. margins r.diabetes@agegrp#sex
(output omitted)
. marginsplot, by(sex) yline(0)
```



With CIs above 0 for six of eight age groups over 40, this graph provides evidence that diabetes is related to higher blood pressure in those over 40.

Continuous covariates

margins and marginsplot are just as useful with continuous covariates as they are with factor variables. As a variation on our ANOVA/regression models, let's move to a logistic regression, using as our dependent variable an indicator for whether a person has high blood pressure. We introduce a continuous covariate—body mass index (BMI), a measure of weight relative to height. High BMI is often associated with high blood pressure. We will allow the effect of BMI to vary across sexes, age groups, and sex/age combinations by fully interacting the covariates.

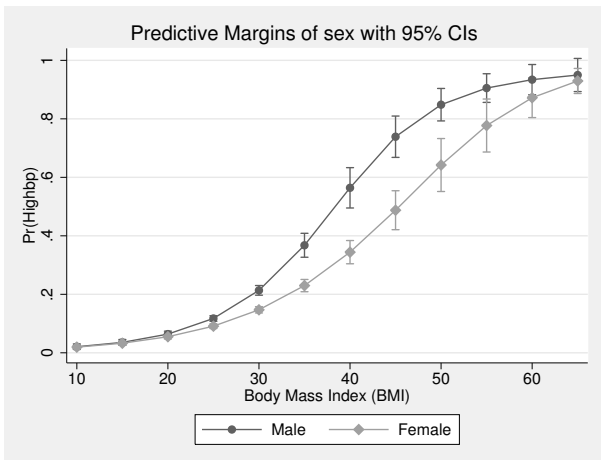
```
. logistic highbp sex##agegrp##c.bmi
```

If we wished, we could perform all the analyses above on this model. Instead of estimating margins, contrasts, and marginal effects on the level of systolic blood pressure, we would be estimating margins, contrasts, and marginal effects on the probability of having high blood pressure. You can see those results by repeating any of the prior commands that involve sex and agegrp. In this section, we will focus on the continuous covariate bmi.

With continuous covariates, rather than specify them in the *marginlist* of margins, we specify the specific values at which we want the covariate evaluated in an at() option. at() options are very flexible, and there are many ways to specify values; see *Syntax of at()* in [R] **margins**.

BMI in our sample ranges from 12.4 to 61.2. Let's estimate the predictive margins for males and females at levels of BMI from 10 through 65 at intervals of 5 and graph the results:

```
. margins sex, at(bmi=(10(5)65))
(output omitted)
. marginsplot, xlabel(10(10)60)
```

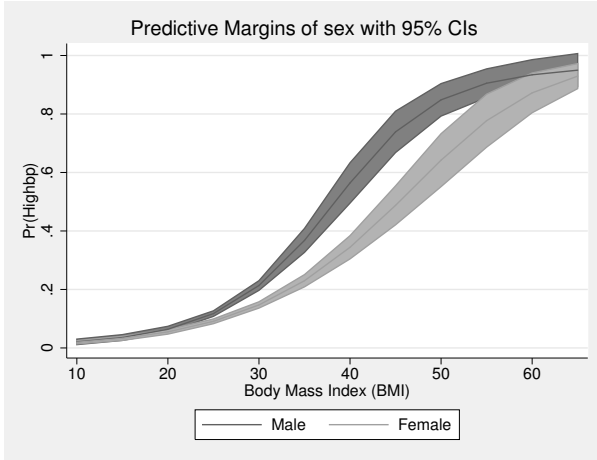


We added the xlabel(10(10)60) option to improve the labeling of the x axis. You may add any *twoway_options* (see [G-3] ***twoway_options***) to the marginsplot command.

For a given BMI, males are generally more susceptible to high blood pressure, though the effect is attenuated by the logistic response when the probabilities approach 0 or 1.

Because bmi is continuous, we might prefer to see the response graphed using a line. We might also prefer that the CIs be plotted as areas. We change the plottype of the response by using the recast() option and the plottype of the CI by using the recastci() option:

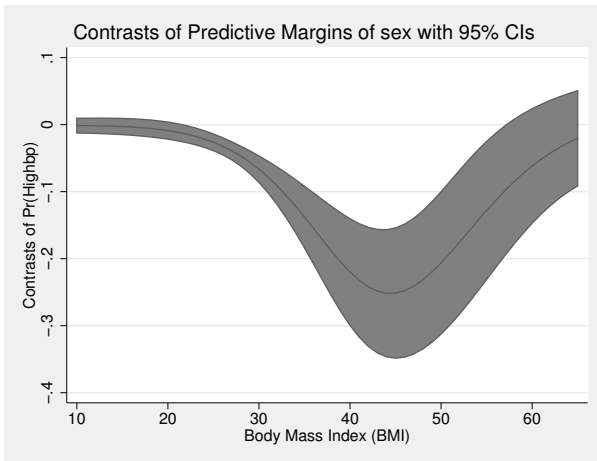
```
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```



The CIs are a little dark for our tastes. You can dim them a bit by reducing the intensity of their color. Adding `ciopts(color(*.8))` to our `marginsplot` command will do that. Any plot option accepted by `twoway rarea` (see [G-2] **graph twoway rarea**) may be specified in a `ciopts()` option.

Given their confidence regions, the male and female profiles appear to be statistically different over most of the range of BMI. As with the profiles of categorical covariates, we can check that assertion by contrasting the two profiles on `sex` and graphing the results. Let's improve the smoothness of the response by specifying intervals of 1 instead of 5.

```
. margins r.sex, at(bmi=(10(1)65))
```
(*output omitted*)
```
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```



We see that the difference between the sexes is largest at a BMI of about 45 and that the sexes respond more similarly with very high and very low BMI. This shape is largely determined by the response of the logistic function, which is attenuated near probabilities 0 and 1, combined with the fact that the lowest measured BMIs are associated with extremely low probabilities of high blood pressure and the highest measured BMIs are associated with high probabilities of high blood pressure.

As when we contrasted profiles of categorical variables, different disciplines will think of this graph differently. Those familiar with designed experiments will be comfortable with the terms used above—this is a contrast of profiles, or a profile of effects, or a profile of a contrast. Many social scientists will prefer to think of this as a graph of marginal or partial effects. For them, this is a plot of the discrete marginal effect of being female for various levels of BMI. They can obtain an identical graph, with labeling more appropriate for the marginal effect's interpretation, by typing

```
. margins, at(bmi=(10(1)65)) dydx(sex)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We can also plot profiles of the response of BMI by levels of another continuous covariate (rather than by the categorical variable `sex`). To do so, we will need another continuous variable in our model. We have been using age groups as a covariate to emphasize the treatment of categorical variables and to allow the effect of age to be flexible. Our dataset also has age recorded in integer years. We replace `agegrp` with continuous `age` in our logistic regression.

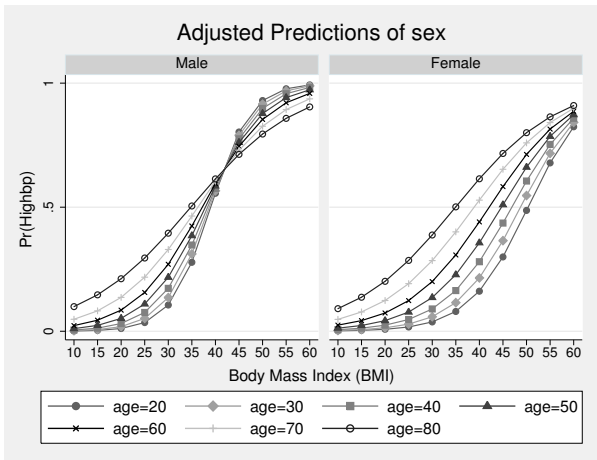
```
. logistic highbp sex##c.age##c.bmi
```

We can now obtain profiles of BMI for different ages by specifying ranges for both `bmi` and `age` in a single `at()` option on the `margins` command:

```
. margins sex, at(bmi=(10(5)60) age=(20(10)80))
```

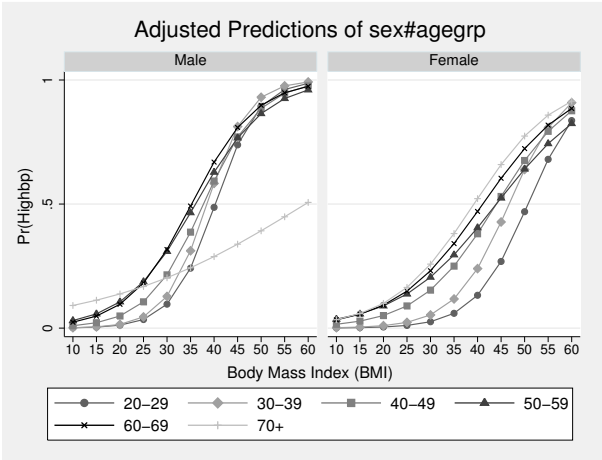
With seven ages specified, we have many profiles, so we will dispense with the CIs by adding the `noci` option and also tidy up the graph by asking for four columns in the legend:

```
. marginsplot, noci by(sex) legend(cols(4))
```



Our model seems to indicate that males have a much sharper reaction to body mass indices than do females. Likewise, younger subjects display a sharper response, while older subjects have a more gradual response with earlier onset. That interpretation might be a result of our parametric treatment of `age`. As it turns out, the interpretation holds if we allow age to take more flexible forms or return to our use of age groups, which allows each of seven age groups to have unique BMI profiles. Here are the commands to perform that analysis:

```
. logistic highbp sex##agegrp##c.bmi
  (output omitted)
. margins sex#agegrp, at(bmi=(10(5)60))
  (output omitted)
. marginsplot, noci by(sex) legend(cols(4))
```



Plots at every value of a continuous covariate

In some cases, the specific values of a continuous covariate are important, and we want to plot the response at those specific values. Return to our logistic example with age treated as a continuous covariate.

```
. logistic highbp sex##c.age##c.bmi
```

We can use a programming trick to extract all the values of age and then supply them in an `at()` option, just as we would any list of values.

```
. levelsof age
. margins sex, at(age=(`r(levels)'))
```

See [P] **levelsof** for a discussion of the `levelsof` command. `levelsof` returns in `r(levels)` the sorted list of unique values of the specified *varlist*, in our case, `age`.

We can then plot the results using `marginsplot`.

This is not a very interesting trick when using our `age` variable, which is recorded as integers from 20 to 74, but the approach will work with almost any continuous variable. In our model, `bmi` might seem more interesting, but there are 9,941 unique values of `bmi` in our dataset. A graph cannot resolve so many different values. For that reason, we usually recommend against plotting at every value of a covariate. Instead, graph at reasonable values over the range of the covariate by using the `at()` option, as we did earlier. This trick is best reserved for variables with a few, or at most a few dozen, unique values.

Contrasts of at() groups—discrete effects

We have previously contrasted across the values of factor variables in our model. Put another way, we have estimated the discrete marginal effects of factor variables. We can do the same for the levels of variables in `at()` specifications and across separate `at()` specifications.

Returning to one of our logistic models and its margins, we earlier estimated the predictive margins of BMI at 5-unit intervals for both sexes. These are the commands we typed:

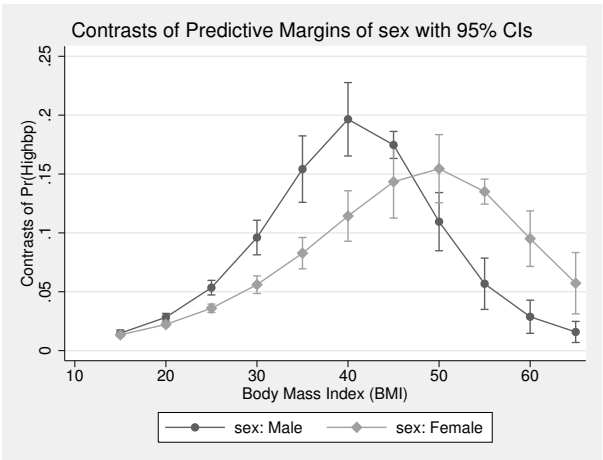
```
. logistic highbp sex##agegrp##c.bmi
. margins sex, at(bmi=(10(5)65))
. marginsplot, xlabel(10(10)60)
```

We can estimate the discrete effects by `sex` of `bmi` moving from 10 to 15, then from 15 to 20, ..., and then from 60 to 65 by contrasting the levels of the `at()` groups using the reverse-adjacent contrast operator (`ar.`). We specify the operator within the `atcontrast()` suboption of the `contrast()` option. We need to specify one other option. By default, `margins, contrast` will apply a contrast to all variables in its *marginlist* when a contrast has been requested. In this case, we do not want to contrast across sexes but rather to contrast across the levels of BMI within each sex. To prevent `margins` from contrasting across the sexes, we specify the `marginswithin` option. Our `margins` command is

```
. margins sex, at(bmi=(10(5)65)) contrast(atcontrast(ar._at) marginswithin)
```

And we graph the results using `marginsplot`:

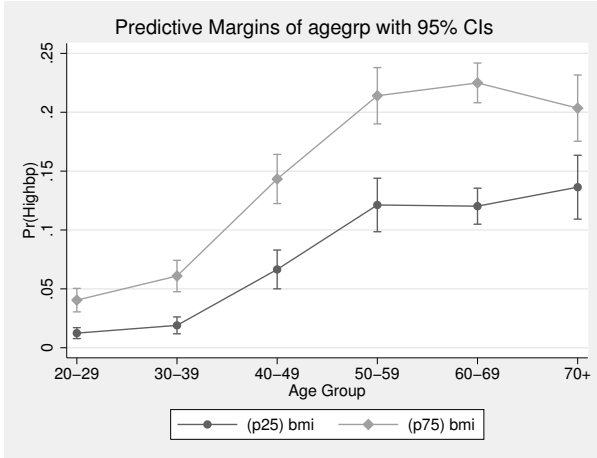
```
. marginsplot
```



The graph shows the contrasts (or if you prefer, discrete changes) in the probability of high blood pressure by sex as one increases BMI in 5-unit increments.

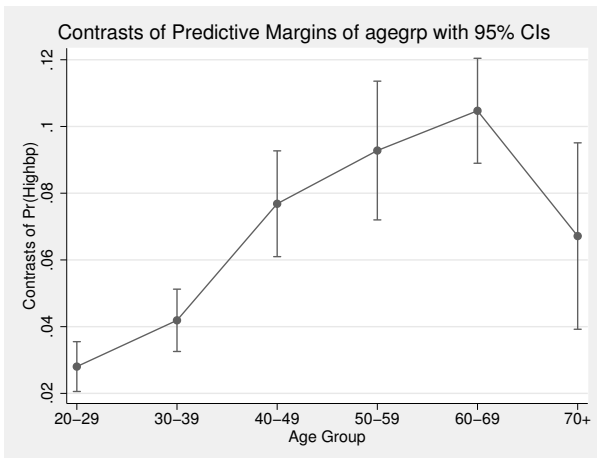
We can even estimate contrasts (discrete effects) across `at()` options. To start, let's compare the age-group profiles of the probability of high blood pressure for those in the 25th and 75th percentile of BMI.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
  (output omitted)
. marginsplot
```



For each age group, people whose BMI is at the 75th percentile have a much higher probability of high blood pressure than those at the 25th percentile. What is that difference in probability and its CI? To contrast across the percentiles of BMI within age groups, we again specify a contrast operator on the `at()` groups using `atcontrast()`, and we also tell `margins` to perform that contrast within the levels of the *marginlist* by using the `marginswithin` option.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
> contrast(atcontrast(r._at) marginswithin)
  (output omitted)
. marginsplot
```



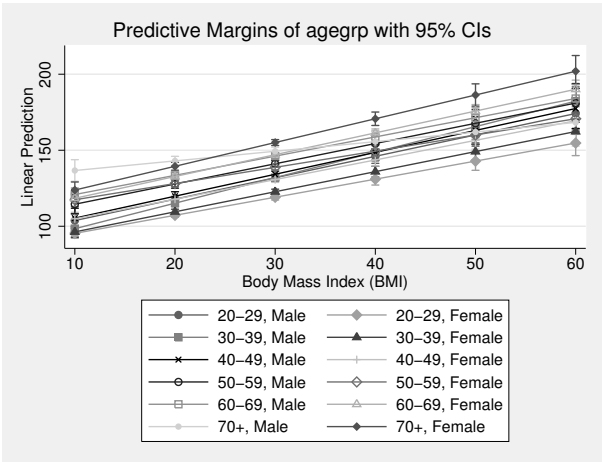
The differences in probability between 25th and 75th BMI percentiles are clearly significantly greater than 0 and appear to be larger for those in higher age groups. The point estimate for those over 70 drops but has a large CI.

Controlling the graph's dimensions

Thus far, `marginsplot` has miraculously done almost exactly what we want in most cases. The things we want on the x axis have been there, the choice of plots has made sense, etc. Some of that luck sprang from the relatively simple analyses we were performing, and some was from careful specification of our `margins` command. Sometimes, we will not be so lucky.

Consider the following `regress`, `margins`, and `marginsplot` commands:

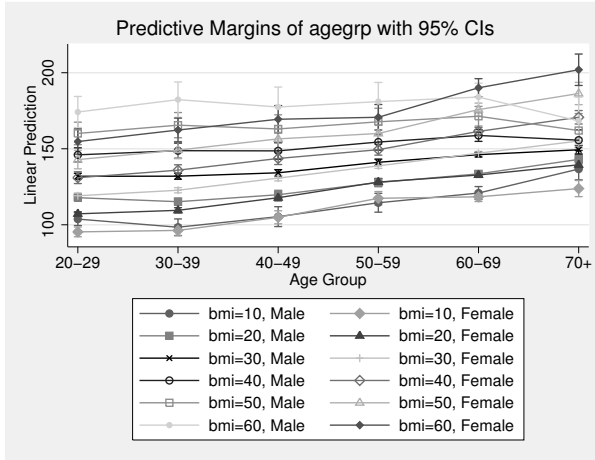
```
. regress bpsystol agegrp##sex##c.bmi
(output omitted)
. margins agegrp, over(sex) at(bmi=(10(10)60))
(output omitted)
. marginsplot
```



By default, `marginsplot` places the levels of the first multilevel `at()` specification on the x axis, and then usually plots the levels of all remaining variables as connected lines. That is what we see in the graph above—`bmi`, the `at()` variable, is on the x axis, and each combination of `agegrp` and `sex` is plotted as a separate connected line. If there is no multilevel `at()` specification, then the first variable in *marginlist* becomes the x axis. There are many more rules, but it is usually best to simply type `marginsplot` and see what happens. If you do not like `marginsplot`'s choices, change them.

What if we wanted `agegrp` on the x axis instead of BMI? We tell `marginsplot` to make that change by specifying `agegrp` in the `xdimension()` option:

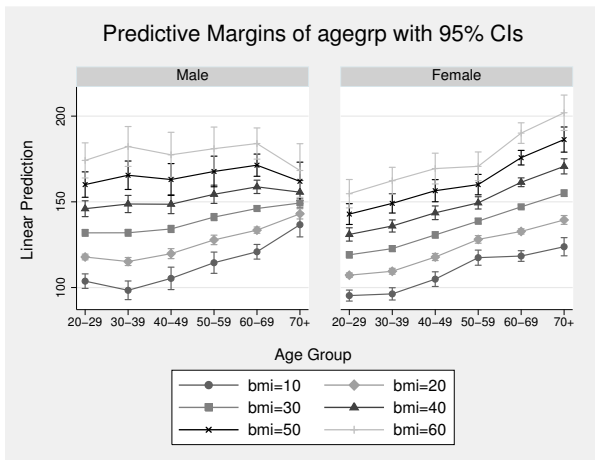
```
. marginsplot, xdimension(agegrp)
  Variables that uniquely identify margins: bmi agegrp sex
```



We have been suppressing the Results window output for `marginsplot`, but that output is helpful if we want to change how things are plotted. You may specify any variable used in your `margins` command in any of the dimension options—`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. (In fact, there are some pseudovariables that you may also specify in some cases; see *Addendum: Advanced uses of dimlist* for details.) `marginsplot` tries to help you narrow your choices by listing a set of variables that uniquely identify all your margins. You are not restricted to this list.

We have a different x axis and a different set of plots, but our graph is still busy and difficult to read. We can make it better by creating separate graph panels for each sex. We do that by adding a `bydimension()` option with `sex` as the argument.

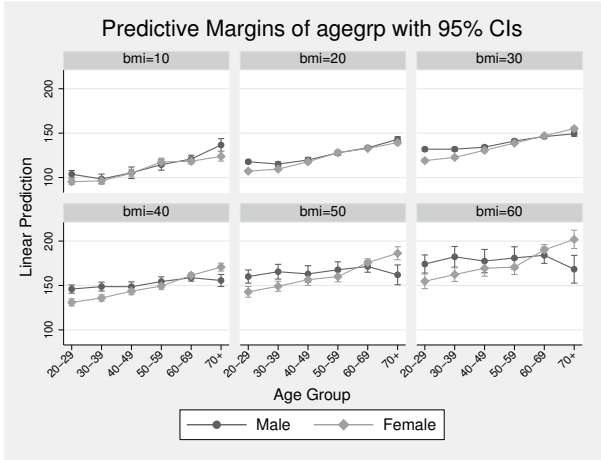
```
. marginsplot, xdimension(agegrp) bydimension(sex)
```



The patterns and the differences between males and females are now easier to see.

If our interest is in comparing males and females, we might even choose to create a separate panel for each level of BMI:

```
. marginsplot, xdimension(agegrp) bydimension(bmi) xlabel(, angle(45))
```



The x-axis labels did not fit, so we angled them.

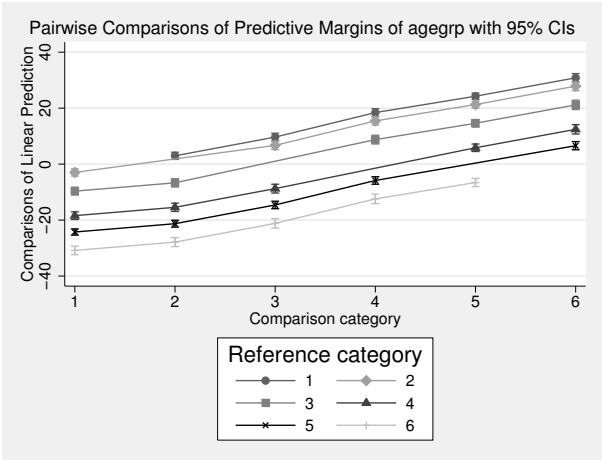
We leave you to explore the use of the `graphdimension()` option. It is much like `bydimension()` but creates separate graphs rather than separate panels. Operationally, the `plotdimension()` option is rarely used. All variables not in the x dimension and not specified elsewhere become the plotted connected lines.

You will likely use the dimension options frequently. This is one of the rare cases where we recommend using the minimal abbreviations of the options—`x()` for `xdimension()`, `plot()` for `plotdimension()`, `by()` for `bydimension()`, and `graph()` for `graphdimension()`. The abbreviations are easy to read and just as meaningful as the full option names. The full names exist to reinforce the relationship between the dimension options.

Pairwise comparisons

`marginsplot` can graph the results of `margins, pwcompare`; see [R] **margins, pwcompare**. We return to one of our ANOVA examples. Here we request pairwise comparisons with the `pwcompare` option of `margins`, and we request Bonferroni-adjusted CIs with the `mcompare()` option:

```
. anova bpsystol agegrp##sex
  (output omitted)
. margins agegrp, pwcompare mcompare(bonferroni)
  (output omitted)
. marginsplot
```



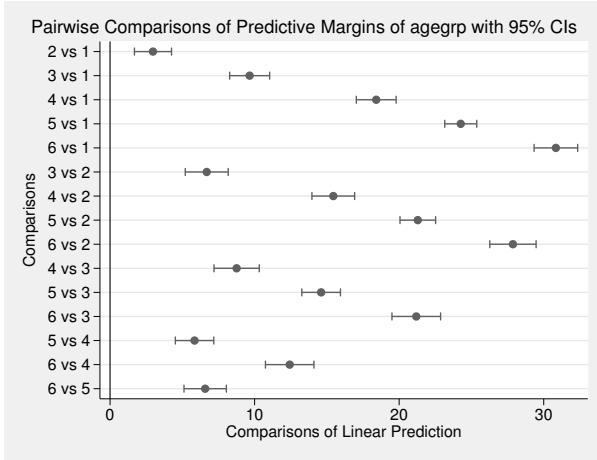
Each connected line plot in the graph represents a reference age-group category for the pairwise comparison. The ticks on the x axis represent comparison age-group categories. So, each plot is a profile for a reference category showing its comparison to each other category.

Horizontal is sometimes better

Another interesting way to graph pairwise comparisons is to simply plot each comparison and label the two categories being compared. This type of graph works better if it is oriented horizontally rather than vertically.

Continuing with the example above, we will switch the graph to horizontal. We will also make several changes to display the graph better. We specify that only `unique` comparisons be plotted. The graph above plotted both 1 versus 2 and 2 versus 1, which are the same comparison with opposite signs. We add a reference line at 0 because we are interested in comparisons that differ from 0. This graph looks better without the connecting lines, so we add the option `recast(scatter)`. We also reverse the y scale so that the smallest levels of age group appear at the top of the axis.

```
. marginsplot, horizontal unique xline(0) recast(scatter) yscale(reverse)
```



All the comparisons differ from 0, so all our age groups are statistically different from each other.

The `horizontal` option can be useful outside of pairwise comparisons. Profile plots are usually oriented vertically. However, when your covariates have long labels or there are many levels at which the margins are being evaluated, the graph may be easier to read when rendered horizontally.

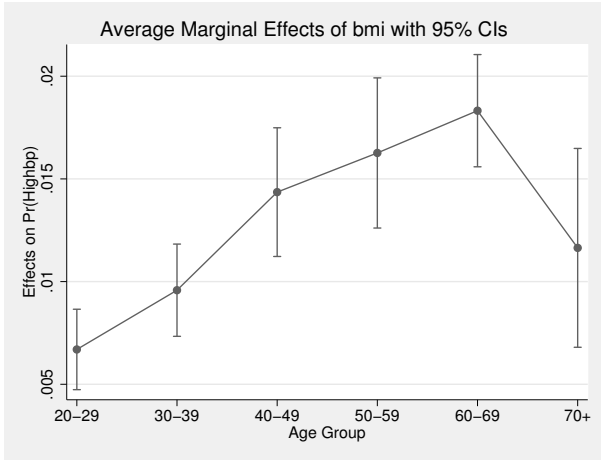
Marginal effects

We have seen how to graph discrete effects for factor variables and continuous variables by using contrasts, and optionally by using the `dydx()` option of `margins`: *Contrasts of margins—effects (discrete marginal effects)* and *Continuous covariates*. Let's now consider graphing instantaneous marginal effects for continuous covariates. Begin by refitting our logistic model of high blood pressure as a function of sex, age, and BMI:

```
. logistic highbp sex##agegrp##c.bmi
```

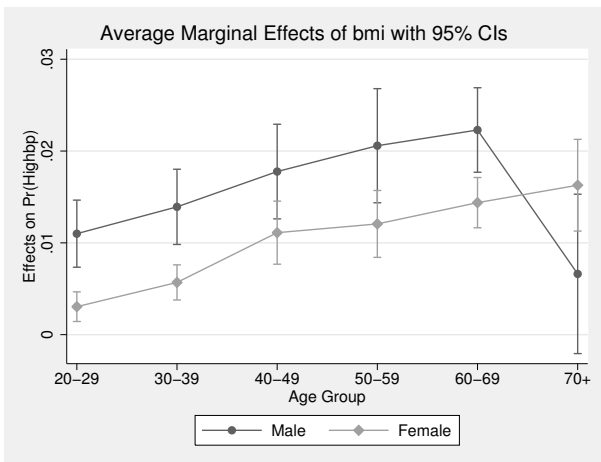
We estimate the average marginal effect of BMI on the probability of high blood pressure for each age group and then graph the results by typing

```
. margins agegrp, dydx(bmi)
(output omitted)
. marginsplot
```



These are the conditional expectations of the marginal effects treating everyone in the sample as though they were in each age group. We can estimate fully conditional marginal effects that do not depend on averaging over the sample by also margining on our one remaining covariate—`sex`.

```
. margins agegrp#sex, dydx(bmi)
(output omitted)
. marginsplot
```



The effect of BMI on the probability of high blood pressure looks to increase with age and is also higher for males than for females.

You may want to confirm that assertion by contrasting across sexes within `agegrp`:

```
. margins r.sex@agegrp, dydx(bmi)
```

Plotting a subset of the results from margins

marginsplot plots all the margins produced by the preceding margins command. If you want a graph that does not include all the margins, then enter a margins command that produces a reduced set of margins. Obvious ways to reduce the number of margins include not specifying some factors or interactions in the *marginlist* of margins, not specifying some at() or over() options, or reducing the values specified in an at() option. A less obvious technique uses selection lists in factor operators to select specific sets of levels from factor variables specified in the *marginlist*.

Instead of typing

```
. margins agegrp
```

which will give you margins for all six age groups in our sample, type

```
. margins i(2/4).agegrp
```

which will give you only three margins—those for groups 2, 3, and 4. See [U] **11.4.3.4 Selecting levels**.

Advanced usage

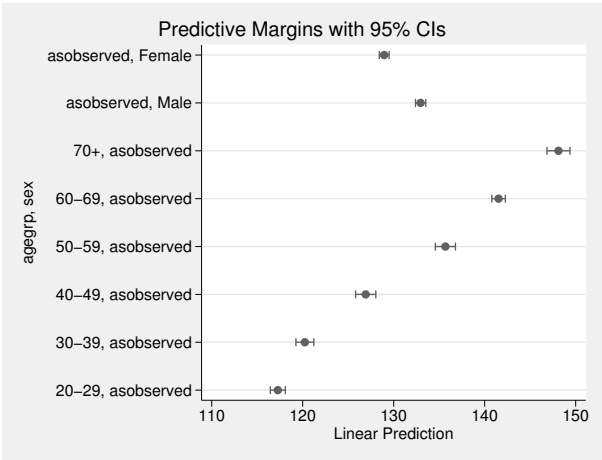
margins is incredibly flexible in the statistics it can estimate and in the grouping of those estimates. Many of the estimates that margins can produce do not make convincing graphs. marginsplot plots the results of any margins command, regardless of whether the resulting graph is easily interpreted. Here we demonstrate some options that can make complicated margins into graphs that are somewhat more useful than those produced by marginsplot's defaults. Others may find truly useful applications for these approaches.

Plots with multiple terms

Margins plots are rarely interesting when you specify multiple terms on your margins command, for example, margins a b. Such plots often compare things that are not comparable. The defaults for marginsplot rarely produce useful plots with multiple terms. Perhaps the most interesting graph in such cases puts all the levels of all the terms together on the vertical axis and plots their margins on the horizontal axis. We do that by including the *marginlist* from margins in an xdimension() option on marginsplot. The long labels on such graphs look better with a horizontal orientation, and there is no need to connect the margin estimates, so we specify the recast(scatter) option.

Using one of our ANOVA examples from earlier,

```
. anova bpsystol agegrp##sex
(output omitted)
. margins agegrp sex
(output omitted)
. marginsplot, xdimension(agegrp sex) horizontal recast(scatter)
```



The "asobserved" notations in the y-axis labels are informing us that, for example, when the margin for females is evaluated, the values of age group are taken as they are observed in the dataset. The margin is computed as an average over those values.

Plots with multiple at() options

Some disciplines like to compute margins at the means of other covariates in their model and others like to compute the response for each observation and then take the means of the response. These correspond to the `margins` options `at((mean) _all)` and `at((asobserved) _all)`. For responses that are linear functions of the coefficients, such as `predict` after `regress`, the two computations yield identical results. For responses that are nonlinear functions of the coefficients, the two computations estimate different things.

Using one of our logistic models of high blood pressure,

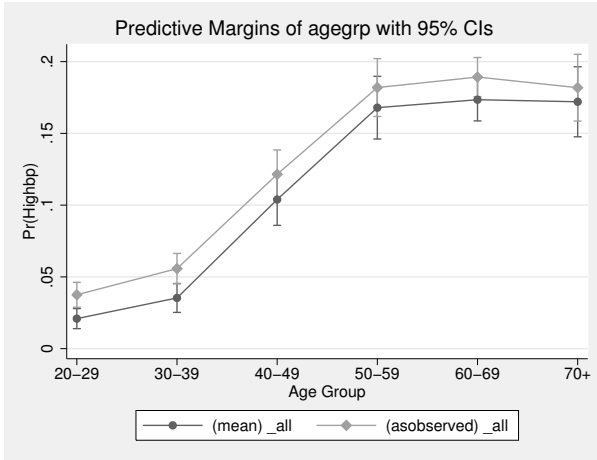
```
. logistic highbp sex##agegrp##c.bmi
```

and computing both sets of margins for each age group,

```
. margins agegrp, at((mean) _all) at((asobserved) _all)
```

we can use `marginsplot` to compare the approaches:

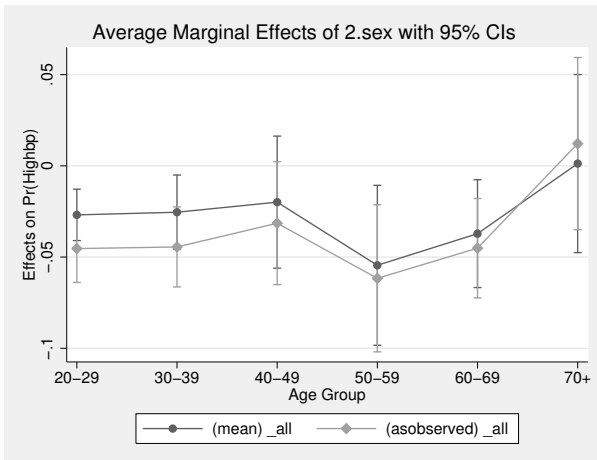
```
. marginsplot
```



In this case, the probabilities of high blood pressure are lower for each age group at the means of `sex` and `bpi` than are the mean probabilities of high blood pressure averaged over the observed values of `sex` and `bpi`.

Such comparisons come up even more frequently when evaluating marginal effects. We can estimate the marginal effects of `sex` at each age group and graph the results by adding `dydx(sex)` to our `margins` command:

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
  (output omitted)
. marginsplot
```



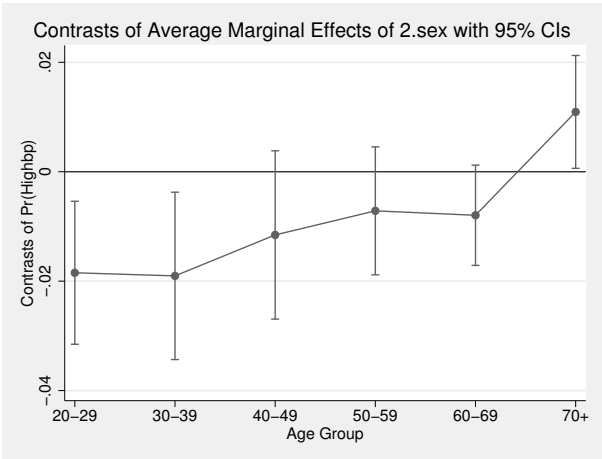
The average marginal effect is smaller for most age groups, but the CIs for both sets of estimates are wide. Can we tell the difference between the estimates? To answer that, we use the now-familiar tactic of taking the contrast of our estimated marginal-effects profiles. That means adding `contrast(atjoint`

`marginswithin`) to our `margins` command. We will also add `mcompare(bonferroni)` to account for the fact that we will be comparing six contrasts.

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
> contrast(atjoint marginswithin) mcompare(bonferroni)
```

We will also add the familiar reference line at 0 to our graph of the contrasts.

```
. marginsplot, yline(0)
```



While the difference in the estimates of marginal effects is not large, we can distinguish the estimates for three of the six age groups.

The `at()` option of `margins` provides far more flexibility than demonstrated above. It can be used to evaluate a response or marginal effect at almost any point of interest or combinations of such points. See *Syntax of at()* in [R] **margins**.

Adding scatterplots of the data

We can add scatterplots of the observed data to our plots of the margins. The NHANES II dataset is too large for this to be interesting, so for this example, we will use `auto.dta`. We fit mileage on whether the care is foreign and on a quadratic in the weight of the car. We convert the weight into tons (U.S. definition) to improve the scaling, and we format the new `tons` variable to improve its labels on the graph. For our graph, we create separate variables for mileage of domestic and of foreign cars. We fit a fully interacted model so that the effect of weight on mileage can be different for foreign and for domestic cars.

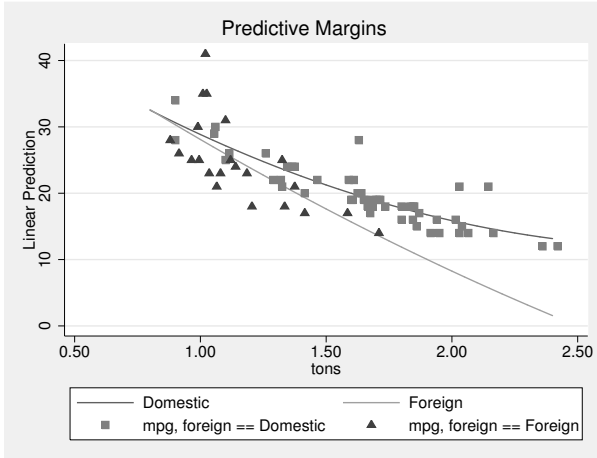
```
. use http://www.stata-press.com/data/r12/auto
. generate tons = weight/2000
. format tons %6.2f
. separate mpg, by(foreign)
. regress mpg foreign##c.tons##c.tons
```

We then estimate the margins over the range of tons, using the option `over(foreign)` to obtain separate estimates for foreign and domestic cars.

```
. margins, at(tons=(.8(.05)2.4)) over(foreign)
```

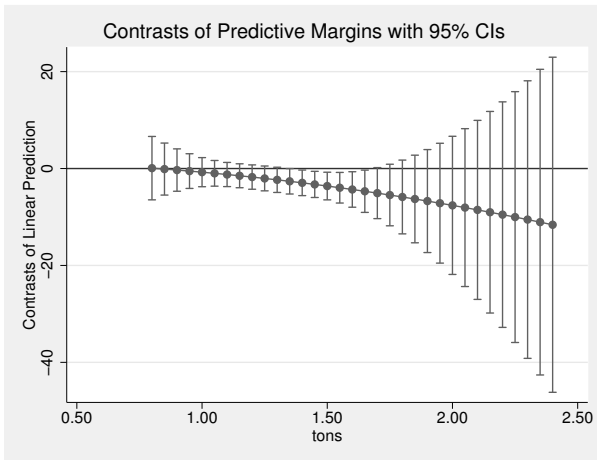
Adding scatterplots of mileage for domestic and foreign cars is easy. We insert into an `addplot()` option of `marginsplot` the same scatterplot syntax for `twoway` that we would type to produce a scatterplot of the data:

```
. marginsplot, addplot(scatter mpg0 tons || scatter mpg1 tons) recast(line) noci
```



Many will be surprised that the mileage profile is higher in 1978 for domestic (U.S. built) cars. Is the difference significant?

```
. margins, at(tons=(.8(.05)2.4)) over(r.for)
  (output omitted)
. marginsplot, yline(0)
```



As we did earlier, we contrast the two profiles. We can discern some difference between the two profiles for midweight vehicles, but otherwise there is insufficient information to believe mileage differs across domestic and foreign cars.

Addendum: Advanced uses of dimlist

dimlist specifies the dimensions from the immediately preceding `margins` command that are to be used for the `marginsplot`'s x axis, plots, subgraphs, and graphs. *dimlist* may contain:

dim	Description
varname	Any variable referenced in the preceding `margins` command.
`at(`*varname*`)`	If a variable is specified in both the *marginlist* or the `over()` option and in the `at()` option of `margins`, then the two uses can be distinguished in `marginsplot` by typing the `at()` variables as `at(`*varname*`)` in *dimlist*.
`_deriv`	If the preceding `margins` command included a `dydx()`, `eyex()`, `dyex()`, or `eydx()` option, *dimlist* may also contain `_deriv` to specify all the variables over which derivatives were taken.
`_term`	If the preceding `margins` command included multiple terms (for example, `margins a b`), then *dimlist* may contain `_term` to enumerate those terms.
`_atopt`	If the preceding `margins` command included multiple `at()` options, then *dimlist* may contain `_atopt` to enumerate those `at()` options.

When the `pairwise` option is specified on `margins`, you may specify dimensions that enumerate the pairwise comparisons.

`_pw`	enumerates all the pairwise comparisons
`_pw0`	enumerates the reference categories of the comparisons
`_pw1`	enumerates the comparison categories of the comparisons

Methods and formulas

`marginsplot` is implemented as an ado-file.

Acknowledgments

StataCorp thanks Phil Ender for consultations and for his programs that demonstrated what could be done in this area. We also thank Michael Mitchell for his generous advice and comprehensive insight into the application of margins and their plots.

Title

matsize — Set the maximum number of variables in a model

Syntax

```
set matsize # [ , permanently ]
```

where 10 ≤ # ≤ 11000 for Stata/MP and Stata/SE and where 10 ≤ # ≤ 800 for Stata/IC.

Description

`set matsize` sets the maximum number of variables that can be included in any of Stata's estimation commands.

For Stata/MP and Stata/SE, the default value is 400, but it may be changed upward or downward. The upper limit is 11,000.

For Stata/IC, the initial value is 400, but it may be changed upward or downward. The upper limit is 800.

This command may not be used with Small Stata; `matsize` is permanently frozen at 100.

Changing `matsize` has no effect on Mata.

Option

`permanently` specifies that, in addition to making the change right now, the `matsize` setting be remembered and become the default setting when you invoke Stata.

Remarks

`set matsize` controls the internal size of matrices that Stata uses. The default of 400 for Stata/IC, for instance, means that linear regression models are limited to 198 independent variables—198 because the constant uses one position and the dependent variable another, making a total of 200.

You may change `matsize` with data in memory, but increasing `matsize` increases the amount of memory consumed by Stata, increasing the probability of page faults and thus of making Stata run more slowly.

▷ Example 1

We wish to fit a model of `y` on the variables `x1` through `x400`. Without thinking, we type

```
. regress y x1-x400
matsize too small
    You have attempted to create a matrix with more than 400 rows or columns
    or to fit a model with more than 400 variables plus ancillary parameters.
    You need to increase matsize by using the set matsize command; see help
    matsize.
r(908);
```

We realize that we need to increase `matsize`, so we type

```
. set matsize 450
. regress y x1-x400
  (output omitted)
```

◁

Programmers should note that the current setting of `matsize` is stored as the c-class value `c(matsize)`; see [P] **creturn**.

maximize — Details of iterative maximization

Syntax

Maximum likelihood optimization

mle_cmd ... [, *options*]

Set default maximum iterations

set maxiter # [, permanently]

options	Description
difficult	use a different stepping algorithm in nonconcave regions
technique(*algorithm_spec*)	maximization technique
iterate(#)	perform maximum of # iterations; default is iterate(16000)
[no]log	display an iteration log of the log likelihood; typically, the default
trace	display current parameter vector in iteration log
gradient	display current gradient vector in iteration log
showstep	report steps within an iteration in iteration log
hessian	display current negative Hessian matrix in iteration log
showtolerance	report the calculated result that is compared to the effective convergence criterion
tolerance(#)	tolerance for the coefficient vector; see *Options* for the defaults
ltolerance(#)	tolerance for the log likelihood; see *Options* for the defaults
nrtolerance(#)	tolerance for the scaled gradient; see *Options* for the defaults
qtolerance(#)	when specified with algorithms bhhh, dfp, or bfgs, the $\mathbf{q} - \mathbf{H}$ matrix is used as the final check for convergence rather than nrtolerance() and the $\mathbf{H}$ matrix; seldom used
nonrtolerance	ignore the nrtolerance() option
from(*init_specs*)	initial values for the coefficients

Description

All Stata commands maximize likelihood functions using `moptimize()` and `optimize()`; see *Methods and formulas* below. Commands use the Newton–Raphson method with step halving and special fixups when they encounter nonconcave regions of the likelihood. For details, see [M-5] **moptimize( )** and [M-5] **optimize( )**. For more information about programming maximum likelihood estimators in ado-files and Mata, see [R] **ml** and the fourth edition of *Maximum Likelihood Estimation with Stata* (Gould, Pitblado, and Poi 2010).

`set maxiter` specifies the default maximum number of iterations for estimation commands that iterate. The initial value is `16000`, and # can be `0` to `16000`. To change the maximum number of iterations performed by a particular estimation command, you need not reset `maxiter`; you can specify the `iterate(#)` option. When `iterate(#)` is not specified, the `maxiter` value is used.

Maximization options

`difficult` specifies that the likelihood function is likely to be difficult to maximize because of nonconcave regions. When the message "not concave" appears repeatedly, `ml`'s standard stepping algorithm may not be working well. `difficult` specifies that a different stepping algorithm be used in nonconcave regions. There is no guarantee that `difficult` will work better than the default; sometimes it is better and sometimes it is worse. You should use the `difficult` option only when the default stepper declares convergence and the last iteration is "not concave" or when the default stepper is repeatedly issuing "not concave" messages and producing only tiny improvements in the log likelihood.

`technique(`*algorithm_spec*`)` specifies how the likelihood function is to be maximized. The following algorithms are allowed. For details, see Gould, Pitblado, and Poi (2010).

`technique(nr)` specifies Stata's modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfp)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, an algorithm is used for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, specifying `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations with the BHHH algorithm followed by 1000 iterations with the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until the maximum number of iterations is reached.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `iterate()`, the optimizer stops and presents the current results. If convergence is declared before this threshold is reached, it will stop when convergence is declared. Specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector. Specifying `iterate(0)` and `from()` together allows you to view results evaluated at a specified coefficient vector; however, not all commands allow the `from()` option. The default value of `iterate(#)` for both estimators programmed internally and estimators programmed with `ml` is the current value of `set maxiter`, which is `iterate(16000)` by default.

`log` and `nolog` specify whether an iteration log showing the progress of the log likelihood is to be displayed. For most commands, the log is displayed by default, and `nolog` suppresses it. For a

few commands (such as the svy maximum likelihood estimators), you must specify log to see the log.

trace adds to the iteration log a display of the current parameter vector.

gradient adds to the iteration log a display of the current gradient vector.

showstep adds to the iteration log a report on the steps within an iteration. This option was added so that developers at StataCorp could view the stepping when they were improving the ml optimizer code. At this point, it mainly provides entertainment.

hessian adds to the iteration log a display of the current negative Hessian matrix.

showtolerance adds to the iteration log the calculated value that is compared with the effective convergence criterion at the end of each iteration. Until convergence is achieved, the smallest calculated value is reported.

shownrtolerance is a synonym of showtolerance.

Below we describe the three convergence tolerances. Convergence is declared when the nrtolerance() criterion is met and either the tolerance() or the ltolerance() criterion is also met.

tolerance(#) specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to tolerance(), the tolerance() convergence criterion is satisfied.

tolerance(1e-4) is the default for estimators programmed with ml.

tolerance(1e-6) is the default.

ltolerance(#) specifies the tolerance for the log likelihood. When the relative change in the log likelihood from one iteration to the next is less than or equal to ltolerance(), the ltolerance() convergence is satisfied.

ltolerance(0) is the default for estimators programmed with ml.

ltolerance(1e-7) is the default.

nrtolerance(#) specifies the tolerance for the scaled gradient. Convergence is declared when $\mathbf{g}\mathbf{H}^{-1}\mathbf{g}' <$ nrtolerance(). The default is nrtolerance(1e-5).

qtolerance(#) when specified with algorithms bhhh, dfp, or bfgs uses the $\mathbf{q} - \mathbf{H}$ matrix as the final check for convergence rather than nrtolerance() and the $\mathbf{H}$ matrix.

Beginning with Stata 12, by default, Stata now computes the $\mathbf{H}$ matrix when the $\mathbf{q}-\mathbf{H}$ matrix passes the convergence tolerance, and Stata requires that $\mathbf{H}$ be concave and pass the nrtolerance() criterion before concluding convergence has occurred.

qtolerance() provides a way for the user to obtain Stata's earlier behavior.

nonrtolerance specifies that the default nrtolerance() criterion be turned off.

---

from() specifies initial values for the coefficients. Not all estimators in Stata support this option. You can specify the initial values in one of three ways: by specifying the name of a vector containing the initial values (for example, from(b0), where b0 is a properly labeled vector); by specifying coefficient names with the values (for example, from(age=2.1 /sigma=7.4)); or by specifying a list of values (for example, from(2.1 7.4, copy)). from() is intended for use when doing bootstraps (see [R] **bootstrap**) and in other special situations (for example, with iterate(0)).

Even when the values specified in `from()` are close to the values that maximize the likelihood, only a few iterations may be saved. Poor values in `from()` may lead to convergence problems.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

`copy` specifies that the list of values or the initialization vector be copied into the initial-value vector by position rather than by name.

Option for set maxiter

`permanently` specifies that, in addition to making the change right now, the `maxiter` setting be remembered and become the default setting when you invoke Stata.

Remarks

Only in rare circumstances would you ever need to specify any of these options, except `nolog`. The `nolog` option is useful for reducing the amount of output appearing in log files.

The following is an example of an iteration log:

```
Iteration 0:   log likelihood = -3791.0251
Iteration 1:   log likelihood =  -3761.738
Iteration 2:   log likelihood = -3758.0632  (not concave)
Iteration 3:   log likelihood = -3758.0447
Iteration 4:   log likelihood = -3757.5861
Iteration 5:   log likelihood =  -3757.474
Iteration 6:   log likelihood = -3757.4613
Iteration 7:   log likelihood = -3757.4606
Iteration 8:   log likelihood = -3757.4606
  (table of results omitted)
```

At iteration 8, the model converged. The message "not concave" at the second iteration is notable. This example was produced using the `heckman` command; its likelihood is not globally concave, so it is not surprising that this message sometimes appears. The other message that is occasionally seen is "backed up". Neither of these messages should be of any concern unless they appear at the final iteration.

If a "not concave" message appears at the last step, there are two possibilities. One is that the result is valid, but there is collinearity in the model that the command did not otherwise catch. Stata checks for obvious collinearity among the independent variables before performing the maximization, but strange collinearities or near collinearities can sometimes arise between coefficients and ancillary parameters. The second, more likely cause for a "not concave" message at the final step is that the optimizer entered a flat region of the likelihood and prematurely declared convergence.

If a "backed up" message appears at the last step, there are also two possibilities. One is that Stata found a perfect maximum and could not step to a better point; if this is the case, all is fine, but this is a highly unlikely occurrence. The second is that the optimizer worked itself into a bad concave spot where the computed gradient and Hessian gave a bad direction for stepping.

If either of these messages appears at the last step, perform the maximization again with the `gradient` option. If the gradient goes to zero, the optimizer has found a maximum that may not be unique but is a maximum. From the standpoint of maximum likelihood estimation, this is a valid result. If the gradient is not zero, it is not a valid result, and you should try tightening up the convergence criterion, or try `ltol(0) tol(1e-7)` to see if the optimizer can work its way out of the bad region.

If you get repeated "not concave" steps with little progress being made at each step, try specifying the `difficult` option. Sometimes `difficult` works wonderfully, reducing the number of iterations and producing convergence at a good (that is, concave) point. Other times, `difficult` works poorly, taking much longer to converge than the default stepper.

Saved results

Maximum likelihood estimators save the following in `e()`:

Scalars

`e(N)`	number of observations	always saved
`e(k)`	number of parameters	always saved
`e(k_eq)`	number of equations in `e(b)`	usually saved
`e(k_eq_model)`	number of equations in overall model test	usually saved
`e(k_dv)`	number of dependent variables	usually saved
`e(df_m)`	model degrees of freedom	always saved
`e(r2_p)`	pseudo-R-squared	sometimes saved
`e(ll)`	log likelihood	always saved
`e(ll_0)`	log likelihood, constant-only model	saved when constant-only model is fit
`e(N_clust)`	number of clusters	saved when `vce(cluster` *clustvar*`)` is specified; see [U] **20.20 Obtaining robust variance estimates**
`e(chi2)`	χ^2	usually saved
`e(p)`	significance of model of test	usually saved
`e(rank)`	rank of `e(V)`	always saved
`e(rank0)`	rank of `e(V)` for constant-only model	saved when constant-only model is fit
`e(ic)`	number of iterations	usually saved
`e(rc)`	return code	usually saved
`e(converged)`	`1` if converged, `0` otherwise	usually saved

Macros		
`e(cmd)`	name of command	always saved
`e(cmdline)`	command as typed	always saved
`e(depvar)`	names of dependent variables	always saved
`e(wtype)`	weight type	saved when weights are specified or implied
`e(wexp)`	weight expression	saved when weights are specified or implied
`e(title)`	title in estimation output	usually saved by commands using `ml`
`e(clustvar)`	name of cluster variable	saved when `vce(cluster` *clustvar*`)` is specified; see [U] **20.20 Obtaining robust variance estimates**
`e(chi2type)`	`Wald` or `LR`; type of model χ^2 test	usually saved
`e(vce)`	*vcetype* specified in `vce()`	saved when command allows (`vce()`)
`e(vcetype)`	title used to label Std. Err.	sometimes saved
`e(opt)`	type of optimization	always saved
`e(which)`	`max` or `min`; whether optimizer is to perform maximization or minimization	always saved
`e(ml_method)`	type of `ml` method	always saved by commands using `ml`
`e(user)`	name of likelihood-evaluator program	always saved
`e(technique)`	from `technique()` option	sometimes saved
`e(singularHmethod)`	`m-marquardt` or `hybrid`; method used when Hessian is singular	sometimes saved[1]
`e(crittype)`	optimization criterion	always saved[1]
`e(properties)`	estimator properties	always saved
`e(predict)`	program used to implement `predict`	usually saved
Matrices		
`e(b)`	coefficient vector	always saved
`e(Cns)`	constraints matrix	sometimes saved
`e(ilog)`	iteration log (up to 20 iterations)	usually saved
`e(gradient)`	gradient vector	usually saved
`e(V)`	variance–covariance matrix of the estimators	always saved
`e(V_modelbased)`	model-based variance	only saved when `e(V)` is neither the OIM nor OPG variance
Functions		
`e(sample)`	marks estimation sample	always saved

1. Type `ereturn list, all` to view these results; see [P] **return**.

See *Saved results* in the manual entry for any maximum likelihood estimator for a list of returned results.

Methods and formulas

Optimization is currently performed by `moptimize()` and `optimize()`, with the former implemented in terms of the latter; see [M-5] **moptimize( )** and [M-5] **optimize( )**. Some estimators use `moptimize()` and `optimize()` directly, and others use the `ml` ado-file interface to `moptimize()`.

Prior to Stata 11, Stata had three separate optimization engines: an internal one used by estimation commands implemented in C code; `ml` implemented in ado-code separately from `moptimize()` and used by most estimators; and `moptimize()` and `optimize()` used by a few recently written

estimators. These days, the internal optimizer and the old version of `ml` are used only under version control. In addition, `arch` and `arima` (see [TS] **arch** and [TS] **arima**) are currently implemented using the old `ml`.

Let L_1 be the log likelihood of the full model (that is, the log-likelihood value shown on the output), and let L_0 be the log likelihood of the "constant-only" model. The likelihood-ratio χ^2 model test is defined as $2(L_1 - L_0)$. The pseudo-R^2 (McFadden 1974) is defined as $1 - L_1/L_0$. This is simply the log likelihood on a scale where 0 corresponds to the "constant-only" model and 1 corresponds to perfect prediction for a discrete model (in which case the overall log likelihood is 0).

Some maximum likelihood routines can report coefficients in an exponentiated form, for example, odds ratios in `logistic`. Let b be the unexponentiated coefficient, s its standard error, and b_0 and b_1 the reported confidence interval for b. In exponentiated form, the point estimate is e^b, the standard error $e^b s$, and the confidence interval e^{b_0} and e^{b_1}. The displayed Z (or t) statistics and p-values are the same as those for the unexponentiated results. This is justified because $e^b = 1$ and $b = 0$ are equivalent hypotheses, and normality is more likely to hold in the b metric.

Title

mean — Estimate means

Syntax

`mean` *varlist* [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`stdize(`*varname*`)`	variable identifying strata for standardization
`stdweight(`*varname*`)`	weight variable for standardization
`nostdrescale`	do not rescale the standard weight variable
if/in/over	
`over(`*varlist*[`, nolabel`]`)`	group over subpopulations defined by *varlist*; optionally, suppress group labels
SE/Cluster	
`vce(`*vcetype*`)`	*vcetype* may be `analytic`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`noheader`	suppress table header
`nolegend`	suppress table legend
display_options	control column formats and line width
`coeflegend`	display legend instead of statistics

`bootstrap`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.
`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.
`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Means

Description

`mean` produces estimates of means, along with standard errors.

Options

Model

`stdize(`*varname*`)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(`*varname*`)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

if/in/over

`over(`*varlist* [`, nolabel`]`)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist*.

When this option is supplied with one variable name, such as `over(`*varname*`)`, the value labels of *varname* are used to identify the subpopulations. If *varname* does not have labeled values (or there are unlabeled values), the values themselves are used, provided that they are nonnegative integers. Noninteger values, negative values, and labels that are not valid Stata names are substituted with a default identifier.

When `over()` is supplied with multiple variable names, each subpopulation is assigned a unique default identifier.

`nolabel` requests that value labels attached to the variables identifying the subpopulations be ignored.

SE/Cluster

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample mean.

Reporting

`level(#)`; see [R] **estimation options**.

`noheader` prevents the table header from being displayed. This option implies `nolegend`.

`nolegend` prevents the table legend identifying the subpopulations from being displayed.

display_options: `cformat(%`*fmt*`)` and `nolstretch`; see [R] **estimation options**.

The following option is available with `mean` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Example 1

Using the fuel data from example 2 of [R] **ttest**, we estimate the average mileage of the cars without the fuel treatment (mpg1) and those with the fuel treatment (mpg2).

```
. use http://www.stata-press.com/data/r12/fuel
. mean mpg1 mpg2
Mean estimation                     Number of obs    =      12
```

	Mean	Std. Err.	[95% Conf.	Interval]
mpg1	21	.7881701	19.26525	22.73475
mpg2	22.75	.9384465	20.68449	24.81551

Using these results, we can test the equality of the mileage between the two groups of cars.

```
. test mpg1 = mpg2
 ( 1)  mpg1 - mpg2 = 0
       F(  1,    11) =    5.04
            Prob > F =    0.0463
```

Example 2

In example 1, the joint observations of mpg1 and mpg2 were used to estimate a covariance between their means.

```
. matrix list e(V)
symmetric e(V)[2,2]
            mpg1        mpg2
mpg1   .62121212
mpg2    .4469697   .88068182
```

If the data were organized this way out of convenience but the two variables represent independent samples of cars (coincidentally of the same sample size), we should reshape the data and use the over() option to ensure that the covariance between the means is zero.

```
. use http://www.stata-press.com/data/r12/fuel
. stack mpg1 mpg2, into(mpg) clear
. mean mpg, over(_stack)
Mean estimation                     Number of obs    =      24
            1: _stack = 1
            2: _stack = 2
```

Over	Mean	Std. Err.	[95% Conf.	Interval]
mpg				
1	21	.7881701	19.36955	22.63045
2	22.75	.9384465	20.80868	24.69132

```
. matrix list e(V)
symmetric e(V)[2,2]
             mpg:       mpg:
               1          2
mpg:1  .62121212
mpg:2          0  .88068182
```

Now we can test the equality of the mileage between the two independent groups of cars.

```
. test [mpg]1 = [mpg]2
 ( 1)  [mpg]1 - [mpg]2 = 0
       F(  1,    23) =    2.04
            Prob > F =    0.1667
```

◁

▷ Example 3: standardized means

Suppose that we collected the blood pressure data from example 2 of [R] **dstdize**, and we wish to obtain standardized high blood pressure rates for each city in 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined. Our rate is really the mean of a variable that indicates whether a sampled individual has high blood pressure. First, we generate the strata and weight variables from our standard distribution, and then use `mean` to compute the rates.

```
. use http://www.stata-press.com/data/r12/hbp, clear
. egen strata = group(age race sex) if inlist(year, 1990, 1992)
(675 missing values generated)
. by strata, sort: gen stdw = _N
. mean hbp, over(city year) stdize(strata) stdweight(stdw)
Mean estimation
N. of std strata =      24          Number of obs    =     455
         Over: city year
    _subpop_1: 1 1990
    _subpop_2: 1 1992
    _subpop_3: 2 1990
    _subpop_4: 2 1992
    _subpop_5: 3 1990
    _subpop_6: 3 1992
    _subpop_7: 5 1990
    _subpop_8: 5 1992
```

Over	Mean	Std. Err.	[95% Conf.	Interval]
hbp				
_subpop_1	.058642	.0296273	.0004182	.1168657
_subpop_2	.0117647	.0113187	-.0104789	.0340083
_subpop_3	.0488722	.0238958	.0019121	.0958322
_subpop_4	.014574	.007342	.0001455	.0290025
_subpop_5	.1011211	.0268566	.0483425	.1538998
_subpop_6	.0810577	.0227021	.0364435	.1256719
_subpop_7	.0277778	.0155121	-.0027066	.0582622
_subpop_8	.0548926	.	.	.

The standard error of the high blood pressure rate estimate is missing for city 5 in 1992 because there was only one individual with high blood pressure; that individual was the only person observed in the stratum of white males 30–35 years old.

By default, mean rescales the standard weights within the over() groups. In the following, we use the nostdrescale option to prevent this, thus reproducing the results in [R] **dstdize**.

```
. mean hbp, over(city year) nolegend stdize(strata) stdweight(stdw)
> nostdrescale
Mean estimation
N. of std strata =      24          Number of obs    =     455
```

Over	Mean	Std. Err.	[95% Conf.	Interval]
hbp				
_subpop_1	.0073302	.0037034	.0000523	.0146082
_subpop_2	.0015432	.0014847	-.0013745	.004461
_subpop_3	.0078814	.0038536	.0003084	.0154544
_subpop_4	.0025077	.0012633	.000025	.0049904
_subpop_5	.0155271	.0041238	.007423	.0236312
_subpop_6	.0081308	.0022772	.0036556	.012606
_subpop_7	.0039223	.0021904	-.0003822	.0082268
_subpop_8	.0088735	0	.	.

Saved results

mean saves the following in e():

Scalars

e(N)	number of observations
e(N_over)	number of subpopulations
e(N_stdize)	number of standard strata
e(N_clust)	number of clusters
e(k_eq)	number of equations in e(b)

e(_p_stdize)	standardizing proportions
e(error)	error code corresponding to e(b)

Functions

e(sample)	marks estimation sample

Methods and formulas

`mean` is implemented as an ado-file.

Methods and formulas are presented under the following headings:

The mean estimator
Survey data
The survey mean estimator
The standardized mean estimator
The poststratified mean estimator
The standardized poststratified mean estimator
Subpopulation estimation

The mean estimator

Let y be the variable on which we want to calculate the mean and y_j an individual observation on y, where $j = 1, \ldots, n$ and n is the sample size. Let w_j be the weight, and if no weight is specified, define $w_j = 1$ for all j. For `aweights`, the w_j are normalized to sum to n. See *The survey mean estimator* for `pweighted` data.

Let W be the sum of the weights

$$W = \sum_{j=1}^{n} w_j$$

The mean is defined as

$$\overline{y} = \frac{1}{W} \sum_{j=1}^{n} w_j y_j$$

The default variance estimator for the mean is

$$\widehat{V}(\overline{y}) = \frac{1}{W(W-1)} \sum_{j=1}^{n} w_j (y_j - \overline{y})^2$$

The standard error of the mean is the square root of the variance.

If x, x_j, and $\overline{x}$ are similarly defined for another variable (observed jointly with y), the covariance estimator between $\overline{x}$ and $\overline{y}$ is

$$\widehat{\mathrm{Cov}}(\overline{x}, \overline{y}) = \frac{1}{W(W-1)} \sum_{j=1}^{n} w_j (x_j - \overline{x})(y_j - \overline{y})$$

Survey data

See [SVY] **variance estimation**, [SVY] **direct standardization**, and [SVY] **poststratification** for discussions that provide background information for the following formulas. The following formulas are derived from the fact that the mean is a special case of the ratio estimator where the denominator variable is one, $x_j = 1$; see [R] **ratio**.

The survey mean estimator

Let Y_j be a survey item for the jth individual in the population, where $j = 1, \ldots, M$ and M is the size of the population. The associated population mean for the item of interest is $\overline{Y} = Y/M$ where

$$Y = \sum_{j=1}^{M} Y_j$$

Let y_j be the survey item for the jth sampled individual from the population, where $j = 1, \ldots, m$ and m is the number of observations in the sample.

The estimator for the mean is $\overline{y} = \widehat{Y}/\widehat{M}$, where

$$\widehat{Y} = \sum_{j=1}^{m} w_j y_j \qquad \text{and} \qquad \widehat{M} = \sum_{j=1}^{m} w_j$$

and w_j is a sampling weight. The score variable for the mean estimator is

$$z_j(\overline{y}) = \frac{y_j - \overline{y}}{\widehat{M}} = \frac{\widehat{M} y_j - \widehat{Y}}{\widehat{M}^2}$$

The standardized mean estimator

Let D_g denote the set of sampled observations that belong to the gth standard stratum and define $I_{D_g}(j)$ to indicate if the jth observation is a member of the gth standard stratum; where $g = 1, \ldots, L_D$ and L_D is the number of standard strata. Also, let π_g denote the fraction of the population that belongs to the gth standard stratum, thus $\pi_1 + \cdots + \pi_{L_D} = 1$. π_g is derived from the `stdweight()` option.

The estimator for the standardized mean is

$$\overline{y}^D = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g}{\widehat{M}_g}$$

where

$$\widehat{Y}_g = \sum_{j=1}^{m} I_{D_g}(j)\, w_j y_j \qquad \text{and} \qquad \widehat{M}_g = \sum_{j=1}^{m} I_{D_g}(j)\, w_j$$

The score variable for the standardized mean is

$$z_j(\overline{y}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\widehat{M}_g y_j - \widehat{Y}_g}{\widehat{M}_g^2}$$

The poststratified mean estimator

Let P_k denote the set of sampled observations that belong to poststratum k and define $I_{P_k}(j)$ to indicate if the jth observation is a member of poststratum k; where $k = 1, \ldots, L_P$ and L_P is the number of poststrata. Also let M_k denote the population size for poststratum k. P_k and M_k are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] **svyset**.

The estimator for the poststratified mean is

$$\overline{y}^P = \frac{\widehat{Y}^P}{\widehat{M}^P} = \frac{\widehat{Y}^P}{M}$$

where

$$\widehat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{P_k}(j)\, w_j y_j$$

and

$$\widehat{M}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k = \sum_{k=1}^{L_P} M_k = M$$

The score variable for the poststratified mean is

$$z_j(\overline{y}^P) = \frac{z_j(\widehat{Y}^P)}{M} = \frac{1}{M} \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left(y_j - \frac{\widehat{Y}_k}{\widehat{M}_k} \right)$$

The standardized poststratified mean estimator

The estimator for the standardized poststratified mean is

$$\overline{y}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^P}{\widehat{M}_g^P}$$

where

$$\widehat{Y}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j)\, w_j y_j$$

and

$$\widehat{M}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j)\, w_j$$

The score variable for the standardized poststratified mean is

$$z_j(\overline{y}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^P z_j(\widehat{Y}_g^P) - \widehat{Y}_g^P z_j(\widehat{M}_g^P)}{(\widehat{M}_g^P)^2}$$

where

$$z_j(\widehat{Y}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\widehat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) - \frac{\widehat{M}_{g,k}}{\widehat{M}_k} \right\}$$

Subpopulation estimation

Let S denote the set of sampled observations that belong to the subpopulation of interest, and define $I_S(j)$ to indicate if the jth observation falls within the subpopulation.

The estimator for the subpopulation mean is $\overline{y}^S = \widehat{Y}^S / \widehat{M}^S$, where

$$\widehat{Y}^S = \sum_{j=1}^{m} I_S(j)\, w_j y_j \qquad \text{and} \qquad \widehat{M}^S = \sum_{j=1}^{m} I_S(j)\, w_j$$

Its score variable is

$$z_j(\overline{y}^S) = I_S(j)\frac{y_j - \overline{y}^S}{\widehat{M}^S} = I_S(j)\frac{\widehat{M}^S y_j - \widehat{Y}^S}{(\widehat{M}^S)^2}$$

The estimator for the standardized subpopulation mean is

$$\overline{y}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^S}{\widehat{M}_g^S}$$

where

$$\widehat{Y}_g^S = \sum_{j=1}^{m} I_{D_g}(j) I_S(j)\, w_j y_j \qquad \text{and} \qquad \widehat{M}_g^S = \sum_{j=1}^{m} I_{D_g}(j) I_S(j)\, w_j$$

Its score variable is

$$z_j(\overline{y}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\widehat{M}_g^S y_j - \widehat{Y}_g^S}{(\widehat{M}_g^S)^2}$$

The estimator for the poststratified subpopulation mean is

$$\overline{y}^{PS} = \frac{\widehat{Y}^{PS}}{\widehat{M}^{PS}}$$

where

$$\widehat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{P_k}(j) I_S(j)\, w_j y_j$$

and

$$\widehat{M}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{P_k}(j) I_S(j)\, w_j$$

Its score variable is

$$z_j(\overline{y}^{PS}) = \frac{\widehat{M}^{PS} z_j(\widehat{Y}^{PS}) - \widehat{Y}^{PS} z_j(\widehat{M}^{PS})}{(\widehat{M}^{PS})^2}$$

where

$$z_j(\widehat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j)\, y_j - \frac{\widehat{Y}_k^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j)\frac{M_k}{\widehat{M}_k}\left\{I_S(j) - \frac{\widehat{M}_k^S}{\widehat{M}_k}\right\}$$

The estimator for the standardized poststratified subpopulation mean is

$$\overline{y}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^{PS}}{\widehat{M}_g^{PS}}$$

where

$$\widehat{Y}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k}\widehat{Y}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) I_S(j)\, w_j y_j$$

and

$$\widehat{M}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k}\widehat{M}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) I_S(j)\, w_j$$

Its score variable is

$$z_j(\overline{y}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{M}_g^{PS})}{(\widehat{M}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j)\frac{M_k}{\widehat{M}_k}\left\{I_{D_g}(j) I_S(j)\, y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k}\right\}$$

and

$$z_j(\widehat{M}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j)\frac{M_k}{\widehat{M}_k}\left\{I_{D_g}(j) I_S(j) - \frac{\widehat{M}_{g,k}^S}{\widehat{M}_k}\right\}$$

Title

mean postestimation — Postestimation tools for mean

Description

The following postestimation commands are available after `mean`:

Command	Description
`estat`	VCE
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Remarks

▷ Example 1

We have a dataset with monthly rates of returns on the Dow and NASDAQ stock indices. We can use `mean` to compute the average quarterly rates of return for the two indices separately;

```
. use http://www.stata-press.com/data/r12/rates
. mean dow nasdaq
Mean estimation                   Number of obs    =       357
```

	Mean	Std. Err.	[95% Conf.	Interval]
dow	.2489137	6.524386	-12.58227	13.0801
nasdaq	10.78477	4.160821	2.601887	18.96765

If you chose just one of the indices for your portfolio, you either did rather well or rather poorly, depending on which one you picked. However, as we now show with the postestimation command `lincom`, if you diversified your portfolio, you would have earned a respectable 5.5% rate of return without having to guess which index would be the better performer.

```
. lincom .5*dow + .5*nasdaq
 ( 1)  .5 dow + .5 nasdaq = 0
```

	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
(1)	5.51684	4.262673	1.29	0.196	-2.866347	13.90003

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

meta — Meta-analysis

Remarks

Stata does not have a meta-analysis command. Stata users, however, have developed an excellent suite of commands for performing meta-analysis, including commands for performing standard and cumulative meta-analysis, commands for producing forest plots and contour-enhanced funnel plots, and commands for nonparametric analysis of publication bias.

Many articles describing these commands have been published in the *Stata Technical Bulletin* and the *Stata Journal*. These articles were updated and published in a cohesive collection: *Meta-Analysis in Stata: An Updated Collection from the Stata Journal*.

In this collection, editor Jonathan Sterne discusses how these articles relate to each other and how they fit in the overall literature of meta-analysis. Sterne has organized the collection into four areas: classic meta-analysis; meta-regression; graphical and analytic tools for detecting bias; and recent advances such as meta-analysis for dose–response curves, diagnostic accuracy, multivariate analysis, and studies containing missing values.

All meta-analysis commands discussed in this collection may be downloaded by visiting http://www.stata-press.com/books/mais.html.

We highly recommend that Stata users interested in meta-analysis read this book. Since the publication of the meta-analysis collection, Kontopantelis and Reeves (2010) published an article in the *Stata Journal* describing a new command `metaan` that performs fixed- or random-effects meta-analysis.

Please also see the following FAQ on the Stata website:

What meta-analysis features are available in Stata?

Title

mfp — Multivariable fractional polynomial models

Syntax

```
mfp [ , options ] : regression_cmd [ yvar1 [ yvar2 ] ] xvarlist [ if ] [ in ] [ weight ]
    [ , regression_cmd_options ]
```

options	Description
Model 2	
`sequential`	use the Royston and Altman model-selection algorithm; default uses closed-test procedure
`cycles(#)`	maximum number of iteration cycles; default is `cycles(5)`
`dfdefault(#)`	default maximum degrees of freedom; default is `dfdefault(4)`
`center(`*cent_list*`)`	specification of centering for the independent variables
`alpha(`*alpha_list*`)`	*p*-values for testing between FP models; default is `alpha(0.05)`
`df(`*df_list*`)`	degrees of freedom for each predictor
`powers(`*numlist*`)`	list of FP powers to use; default is `powers(-2 -1(.5)1 2 3)`
Adv. model	
`xorder(+|-|n)`	order of entry into model-selection algorithm; default is `xorder(+)`
`select(`*select_list*`)`	nominal *p*-values for selection on each predictor
`xpowers(`*xp_list*`)`	FP powers for each predictor
`zero(`*varlist*`)`	treat nonpositive values of specified predictors as zero when FP transformed
`catzero(`*varlist*`)`	add indicator variable for specified predictors
`all`	include out-of-sample observations in generated variables
Reporting	
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats and line width

regression_cmd_options	Description
Adv. model	
regression_cmd_options	options appropriate to the regression command in use

All weight types supported by *regression_cmd* are allowed; see [U] **11.1.6 weight**.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

`fracgen` may be used to create new variables containing fractional polynomial powers. See [R] **fracpoly**.

where

regression_cmd may be clogit, glm, intreg, logistic, logit, mlogit, nbreg, ologit, oprobit, poisson, probit, qreg, regress, rreg, stcox, stcrreg, streg, or xtgee.

$yvar_1$ is not allowed for streg, stcrreg, and stcox. For these commands, you must first stset your data.

$yvar_1$ and $yvar_2$ must both be specified when *regression_cmd* is intreg.

xvarlist has elements of type *varlist* and/or (*varlist*), for example, x1 x2 (x3 x4 x5)
Elements enclosed in parentheses are tested jointly for inclusion in the model and are not eligible for fractional polynomial transformation.

Menu

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial models

Description

mfp selects the multivariable fractional polynomial (MFP) model that best predicts the outcome variable from the right-hand-side variables in *xvarlist*.

Options

Model 2

sequential chooses the sequential fractional polynomial (FP) selection algorithm (see *Methods of FP model selection*).

cycles(#) sets the maximum number of iteration cycles permitted. cycles(5) is the default.

dfdefault(#) determines the default maximum degrees of freedom (df) for a predictor. The default is dfdefault(4) (second-degree FP).

center(*cent_list*) defines the centering of the covariates $xvar_1$, $xvar_2$, ... of *xvarlist*. The default is center(mean), except for binary covariates, where it is center(#), with # being the lower of the two distinct values of the covariate. A typical item in *cent_list* is *varlist*:{mean|#|no}. Items are separated by commas. The first item is special in that *varlist* is optional, and if it is omitted, the default is reset to the specified value (mean, #, or no). For example, center(no, age:mean) sets the default to no (that is, no centering) and the centering of age to mean.

alpha(*alpha_list*) sets the significance levels for testing between FP models of different degrees. The rules for *alpha_list* are the same as those for *df_list* in the df() option (see below). The default nominal p-value (significance level, selection level) is 0.05 for all variables.

Example: alpha(0.01) specifies that all variables have an FP selection level of 1%.

Example: alpha(0.05, weight:0.1) specifies that all variables except weight have an FP selection level of 5%; weight has a level of 10%.

df(*df_list*) sets the df for each predictor. The df (not counting the regression constant, _cons) is twice the degree of the FP, so, for example, an *xvar* fit as a second-degree FP (FP2) has 4 df. The first item in *df_list* may be either # or *varlist*:#. Subsequent items must be *varlist*:#. Items are separated by commas, and *varlist* is specified in the usual way for variables. With the first type of item, the df for all predictors is taken to be #. With the second type of item, all members of *varlist* (which must be a subset of *xvarlist*) have # df.

The default number of degrees of freedom for a predictor of type *varlist* specified in *xvarlist* but not in *df_list* is assigned according to the number of distinct (unique) values of the predictor, as follows:

# of distinct values	Default df
1	(invalid predictor)
2–3	1
4–5	min(2, `dfdefault()`)
≥ 6	`dfdefault()`

Example: `df(4)`
All variables have 4 df.

Example: `df(2, weight displ:4)`
`weight` and `displ` have 4 df; all other variables have 2 df.

Example: `df(weight displ:4, mpg:2)`
`weight` and `displ` have 4 df, `mpg` has 2 df; all other variables have default df.

`powers(`*numlist*`)` is the set of FP powers to be used. The default set is -2, -1, -0.5, 0, 0.5, 1, 2, 3 (0 means log).

Adv. model

`xorder(+|-|n)` determines the order of entry of the covariates into the model-selection algorithm. The default is `xorder(+)`, which enters them in decreasing order of significance in a multiple linear regression (most significant first). `xorder(-)` places them in reverse significance order, whereas `xorder(n)` respects the original order in *xvarlist*.

`select(`*select_list*`)` sets the nominal p-values (significance levels) for variable selection by backward elimination. A variable is dropped if its removal causes a nonsignificant increase in deviance. The rules for *select_list* are the same as those for *df_list* in the `df()` option (see above). Using the default selection level of 1 for all variables forces them all into the model. Setting the nominal p-value to be 1 for a given variable forces it into the model, leaving others to be selected or not. The nominal p-value for elements of *xvarlist* bound by parentheses is specified by including (*varlist*) in *select_list*.

Example: `select(0.05)`
All variables have a nominal p-value of 5%.

Example: `select(0.05, weight:1)`
All variables except `weight` have a nominal p-value of 5%; `weight` is forced into the model.

Example: `select(a (b c):0.05)`
All variables except `a`, `b`, and `c` are forced into the model. `b` and `c` are tested jointly with 2 df at the 5% level, and `a` is tested singly at the 5% level.

`xpowers(`*xp_list*`)` sets the permitted FP powers for covariates individually. The rules for *xp_list* are the same as for *df_list* in the `df()` option. The default selection is the same as that for the `powers()` option.

Example: `xpowers(-1 0 1)`
All variables have powers -1, 0, 1.

Example: `xpowers(x5:-1 0 1)`
All variables except `x5` have default powers; `x5` has powers -1, 0, 1.

`zero(`*varlist*`)` treats negative and zero values of members of *varlist* as zero when FP transformations are applied. By default, such variables are subjected to a preliminary linear transformation to avoid negative and zero values (see [R] **fracpoly**). *varlist* must be part of *xvarlist*.

`catzero(`*varlist*`)` is a variation on `zero()`; see *Zeros and zero categories* below. *varlist* must be part of *xvarlist*.

regression_cmd_options may be any of the options appropriate to *regression_cmd*.

`all` includes out-of-sample observations when generating the FP variables. By default, the generated FP variables contain missing values outside the estimation sample.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Iteration report
Estimation algorithm
Methods of FP model selection
Zeros and zero categories

For elements in *xvarlist* not enclosed in parentheses, `mfp` leaves variables in the data named I*xvar*__1, I*xvar*__2, ..., where *xvar* represents the first four letters of the name of $xvar_1$, and so on, for $xvar_2$, $xvar_3$, etc. The new variables contain the best-fitting FP powers of $xvar_1$, $xvar_2$, ...

Iteration report

By default, for each continuous predictor, *x*, `mfp` compares null, linear, and FP1 models for *x* with an FP2 model. The deviance for each of these nested submodels is given in the column labeled "Deviance". The line labeled "Final" gives the deviance for the selected model and its powers. All the other predictors currently selected are included, with their transformations (if any). For models specified as having 1 df, the only choice is whether the variable enters the model.

Estimation algorithm

The estimation algorithm in `mfp` processes the *xvars* in turn. Initially, `mfp` silently arranges *xvarlist* in order of increasing *p*-value (that is, of decreasing statistical significance) for omitting each predictor from the model comprising *xvarlist*, with each term linear. The aim is to model relatively important variables before unimportant ones. This approach may help to reduce potential model-fitting difficulties caused by collinearity or, more generally, "concurvity" among the predictors. See the `xorder()` option above for details on how to change the ordering.

At the initial cycle, the best-fitting FP function for $xvar_1$ (the first of *xvarlist*) is determined, with all the other variables assumed to be linear. Either the default or the alternative procedure is used (see *Methods of FP model selection* below). The functional form (but not the estimated regression coefficients) for $xvar_1$ is kept, and the process is repeated for $xvar_2$, $xvar_3$, etc. The first iteration concludes when all the variables have been processed in this way. The next cycle is similar, except that the functional forms from the initial cycle are retained for all variables except the one currently being processed.

A variable whose functional form is prespecified to be linear (that is, to have 1 df) is tested for exclusion within the above procedure when its nominal p-value (selection level) according to `select()` is less than 1; otherwise, it is included.

Updating of FP functions and candidate variables continues until the functions and variables included in the overall model do not change (convergence). Convergence is usually achieved within 1–4 cycles.

Methods of FP model selection

`mfp` includes two algorithms for FP model selection, both of which combine backward elimination with the selection of an FP function. For each continuous variable in turn, they start from a most-complex permitted FP model and attempt to simplify the model by reducing the degree. The default algorithm resembles a closed-test procedure, a sequence of tests maintaining the overall type I error rate at a prespecified nominal level, such as 5%. All significance tests are approximate; therefore, the algorithm is not precisely a closed-test procedure (Royston and Sauerbrei 2008, chap. 6).

The closed-test algorithm for choosing an FP model with maximum permitted degree $m = 2$ (that is, an FP2 model with 4 df) for one continuous predictor, x, is as follows:

1. Inclusion: Test FP2 against the null model for x on 4 df at the significance level determined by `select()`. If x is significant, continue; otherwise, drop x from the model.
2. Nonlinearity: Test FP2 against a straight line in x on 3 df at the significance level determined by `alpha()`. If significant, continue; otherwise, stop, with the chosen model for x being a straight line.
3. Simplification: Test FP2 against FP1 on 2 df at the significance level determined by `alpha()`. If significant, the final model is FP2; otherwise, it is FP1.

The first step is omitted if x is to be retained in the model, that is, if its nominal p-value, according to the `select()` option, is 1.

An alternative algorithm is available with the `sequential` option, as originally suggested by Royston and Altman (1994):

1. Test FP2 against FP1 on 2 df at the `alpha()` significance level. If significant, the final model is FP2; otherwise, continue.
2. Test FP1 against a straight line on 1 df at the `alpha()` level. If significant, the final model is FP1; otherwise, continue.
3. Test a straight line against omitting x on 1 df at the `select()` level. If significant, the final model is a straight line; otherwise, drop x.

The final step is omitted if x is to be retained in the model, that is, if its nominal p-value, according to the `select()` option, is 1.

If x is uninfluential, the overall type I error rate of this procedure is about double that of the closed-test procedure, for which the rate is close to the nominal value. This inflated type I error rate confers increased apparent power to detect nonlinear relationships.

Zeros and zero categories

The `zero()` option permits fitting an FP model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor in an epidemiological study. Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between one and

zero cigarettes. To allow for this, the risk may be modeled as constant for the nonsmokers and as an FP function of the number of cigarettes for the smokers:

```
. generate byte nonsmokr = cond(n_cigs==0, 1, 0) if n_cigs != .
. mfp, zero(n_cigs) df(4, nonsmokr:1): logit case n_cigs nonsmokr age
```

Omission of `zero(n_cigs)` would cause `n_cigs` to be transformed before analysis by the addition of a suitable constant, probably 1.

A closely related approach involves the `catzero()` option. The command

```
. mfp, catzero(n_cigs): logit case n_cigs age
```

would achieve a similar result to the previous command but with important differences. First, `mfp` would create the equivalent of the binary variable `nonsmokr` automatically and include it in the model. Second, the two smoking variables would be treated as one predictor in the model. With the `select()` option active, the two variables would be tested jointly for inclusion in the model. A modified version is described in Royston and Sauerbrei (2008, sec. 4.15).

▷ Example 1

We illustrate two of the analyses performed by Sauerbrei and Royston (1999). We use `brcancer.dta`, which contains prognostic factors data from the German Breast Cancer Study Group of patients with node-positive breast cancer. The response variable is recurrence-free survival time (`rectime`), and the censoring variable is `censrec`. There are 686 patients with 299 events. We use Cox regression to predict the log hazard of recurrence from prognostic factors, of which five are continuous (`x1`, `x3`, `x5`, `x6`, `x7`) and three are binary (`x2`, `x4a`, `x4b`). Hormonal therapy (`hormon`) is known to reduce recurrence rates and is forced into the model. We use `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. We set the nominal p-value for variable and FP selection to 0.05 for all variables except `hormon`, for which it is set to 1:

```
. use http://www.stata-press.com/data/r12/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
  (output omitted)
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr

Deviance: 3420.724.
```

Some explanation of the output from the model-selection algorithm is desirable. Consider the first few lines of output in the iteration log:

```
1. Deviance for model with all terms untransformed =  3471.637, 686 observations
   Variable     Model (vs.)   Deviance  Dev diff.   P      Powers    (vs.)
------------------------------------------------------------------------------
2. x5           null   FP2    3503.610    61.366  0.000*   .          .5 3
3.              lin.          3471.637    29.393  0.000+   1
4.              FP1           3449.203     6.959  0.031+   0
5.              Final         3442.244                     .5 3
```

Line 1 gives the deviance ($-2 \times$ log partial likelihood) for the Cox model with all terms linear, the place where the algorithm starts. The model is modified variable by variable in subsequent steps. The most significant linear term turns out to be `x5`, which is therefore processed first. Line 2 compares the best-fitting FP2 for `x5` with a model omitting `x5`. The FP has powers (0.5, 3), and the test for inclusion of `x5` is highly significant. The reported deviance of 3,503.610 is of the null model, not for the FP2 model. The deviance for the FP2 model may be calculated by subtracting the deviance difference (`Dev diff.`) from the reported deviance, giving $3{,}503.610 - 61.366 = 3{,}442.244$. Line 3 shows that the FP2 model is also a significantly better fit than a straight line (`lin.`) and line 4 that FP2 is also somewhat better than FP1 ($p = 0.031$). Thus at this stage in the model-selection procedure, the final model for `x5` (line 5) is FP2 with powers (0.5, 3). The overall model with an FP2 for `x5` and all other terms linear has a deviance of 3,442.244.

After all the variables have been processed (cycle 1) and reprocessed (cycle 2) in this way, convergence is achieved because the functional forms (FP powers and variables included) after cycle 2 are the same as they were after cycle 1. The model finally chosen is Model II as given in tables 3 and 4 of Sauerbrei and Royston (1999). Because of scaling of variables, the regression coefficients reported there are different, but the model and its deviance are identical. The model includes `x1` with powers $(-2, -0.5)$, `x4a`, `x5` with powers $(-2, -1)$, and `x6` with power 0.5. There is strong evidence of nonlinearity for `x1` and for `x5`, the deviance differences for comparison with a straight-line model (`FP2 vs lin.`) being, respectively, 19.3 and 31.1 at convergence (cycle 2). Predictors `x2`, `x3`, `x4b`, and `x7` are dropped, as may be seen from their status `out` in the table `Final multivariable fractional polynomial model for _t` (the assumed *depvar* when using `stcox`).

All predictors except `x4a` and `hormon`, which are binary, have been centered on the mean of the original variable. For example, the mean of `x1` (age) is 53.05 years. The first FP-transformed variable for `x1` is `x1^-2` and is created by the expression `gen double Ix1__1 = X^-2-.0355 if e(sample)`. The value 0.0355 is obtained from $(53.05/10)^{-2}$. The division by 10 is applied automatically to improve the scaling of the regression coefficient for `Ix1__1`.

According to Sauerbrei and Royston (1999), medical knowledge dictates that the estimated risk function for x5 (number of positive nodes), which was based on the above FP with powers $(-2, -1)$, should be monotonic, but it was not. They improved Model II by estimating a preliminary exponential transformation, x5e $= \exp(-0.12 \cdot$ x5$)$, for x5 and fitting a degree 1 FP for x5e, thus obtaining a monotonic risk function. The value of -0.12 was estimated univariately using nonlinear Cox regression with the ado-file boxtid (Royston and Ambler 1999b, 1999d). To ensure a negative exponent, Sauerbrei and Royston (1999) restricted the powers for x5e to be positive. Their Model III may be fit by using the following command:

```
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon
```

Other than the customization for x5e, the command is the same as it was before. The resulting model is as reported in table 4 of Sauerbrei and Royston (1999):

```
. use http://www.stata-press.com/data/r12/brcancer, clear
(German breast cancer data)
. stset rectime, fail(censrec)
  (output omitted)
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon, nohr
  (output omitted)

Saved results

In addition to what *regression_cmd* saves, `mfp` saves the following in `e()`:

Scalars

`e(fp_nx)`	number of predictors in *xvarlist*
`e(fp_dev)`	deviance of final model fit
`e(Fp_id#)`	initial degrees of freedom for the #th element of *xvarlist*
`e(Fp_fd#)`	final degrees of freedom for the #th element of *xvarlist*
`e(Fp_al#)`	FP selection level for the #th element of *xvarlist*
`e(Fp_se#)`	backward elimination selection level for the #th element of *xvarlist*

Macros

`e(fp_cmd)`	`fracpoly`
`e(fp_cmd2)`	`mfp`
`e(cmdline)`	command as typed
`e(fracpoly)`	command used to fit the selected model using `fracpoly`
`e(fp_fvl)`	variables in final model
`e(fp_depv)`	$yvar_1$ ($yvar_2$)
`e(fp_opts)`	estimation command options
`e(fp_x1)`	first variable in *xvarlist*
`e(fp_x2)`	second variable in *xvarlist*
`...`	
`e(fp_xN)`	last variable in *xvarlist*, N=`e(fp_nx)`
`e(fp_k1)`	power for first variable in *xvarlist* (*)
`e(fp_k2)`	power for second variable in *xvarlist* (*)
`...`	
`e(fp_kN)`	power for last var. in *xvarlist* (*), N=`e(fp_nx)`

Note: (*) contains '`.`' if the variable is not selected in the final model.

Methods and formulas

`mfp` is implemented as an ado-file.

Acknowledgments

`mfp` is an update of `mfracpol` by Royston and Ambler (1998).

Title

mfp postestimation — Postestimation tools for mfp

Description

The following postestimation commands are of special interest after `mfp`:

Command	Description
`fracplot`	plot data and fit from most recently fit fractional polynomial model
`fracpred`	create variable containing prediction, deviance residuals, or SEs of fitted values

For `fracplot` and `fracpred`, see [R] **fracpoly postestimation**.

The following standard postestimation commands are also available if available after *regression_cmd*:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

misstable — Tabulate missing values

Syntax

Report counts of missing values

```
misstable summarize [varlist] [if] [in] [, summarize_options]
```

Report pattern of missing values

```
misstable patterns [varlist] [if] [in] [, patterns_options]
```

Present a tree view of the pattern of missing values

```
misstable tree [varlist] [if] [in] [, tree_options]
```

List the nesting rules that describe the missing-value pattern

```
misstable nested [varlist] [if] [in] [, nested_options]
```

summarize_options	Description
`all`	show all variables
`showzeros`	show zeros in table
`generate(`*stub* `[, exok])`	generate missing-value indicators

patterns_options	Description
`asis`	use variables in order given
`frequency`	report frequencies instead of percentages
`exok`	treat `.a`, `.b`, ..., `.z` as nonmissing
`replace`	replace data in memory with dataset of patterns
`clear`	okay to `replace` even if original unsaved
`bypatterns`	list by patterns rather than by frequency

tree_options	Description
`asis`	use variables in order given
`frequency`	report frequencies instead of percentages
`exok`	treat `.a`, `.b`, ..., `.z` as nonmissing

nested_options	Description
`exok`	treat `.a`, `.b`, ..., `.z` as nonmissing

In addition, programmer's option nopreserve is allowed with all syntaxes; see [P] **nopreserve option**.

Menu

Statistics > Summaries, tables, and tests > Tables > Tabulate missing values

Description

misstable makes tables that help you understand the pattern of missing values in your data.

Options for misstable summarize

all specifies that the table should include all the variables specified or all the variables in the dataset. The default is to include only numeric variables that contain missing values.

showzeros specifies that zeros in the table should display as 0 rather than being omitted.

generate(*stub* [, exok]) requests that a missing-value indicator *newvar*, a new binary variable containing 0 for complete observations and 1 for incomplete observations, be generated for every numeric variable in *varlist* containing missing values. If the all option is specified, missing-value indicators are created for all the numeric variables specified or for all the numeric variables in the dataset. If exok is specified within generate(), the extended missing values .a, .b, ..., .z are treated as if they do not designate missing.

For each variable in *varlist*, *newvar* is the corresponding variable name *varname* prefixed with *stub*. If the total length of *stub* and *varname* exceeds 32 characters, *newvar* is abbreviated so that its name does not exceed 32 characters.

Options for misstable patterns

asis, frequency, and exok – see *Common options* below.

replace specifies that the data in memory be replaced with a dataset corresponding to the table just displayed; see *misstable patterns* under *Remarks* below.

clear is for use with replace; it specifies that it is okay to change the data in memory even if they have not been saved to disk.

bypatterns specifies the table be ordered by pattern rather than by frequency. That is, bypatterns specifies that patterns containing one incomplete variable be listed first, followed by those for two incomplete variables, and so on. The default is to list the most frequent pattern first, followed by the next most frequent pattern, etc.

Options for misstable tree

asis, frequency, and exok – see *Common options* below.

Option for misstable nested

`exok` – see *Common options* below.

Common options

`asis` specifies that the order of the variables in the table be the same as the order in which they are specified on the `misstable` command. The default is to order the variables by the number of missing values, and within that, by the amount of overlap of missing values.

`frequency` specifies that the table should report frequencies instead of percentages.

`exok` specifies that the extended missing values `.a`, `.b`, ..., `.z` should be treated as if they do not designate missing. Some users use extended missing values to designate values that are missing for a known and valid reason.

`nopreserve` is a programmer's option allowed with all `misstable` commands; see [P] **nopreserve option**.

Remarks

Remarks are presented under the following headings:

misstable summarize
misstable patterns
misstable tree
misstable nested
Execution time of misstable nested

In what follows, we will use data from a 125-observation, fictional, student-satisfaction survey:

```
. use http://www.stata-press.com/data/r12/studentsurvey
(Student Survey)
. summarize
```

Variable	Obs	Mean	Std. Dev.	Min	Max
m1	125	2.456	.8376619	1	4
m2	125	2.472	.8089818	1	4
age	122	18.97541	.8763477	17	21
female	122	.5245902	.5014543	0	1
dept	116	2.491379	1.226488	1	4
offcampus	125	.36	.4819316	0	1
comment	0				

The `m1` and `m2` variables record the student's satisfaction with teaching and with academics. `comment` is a string variable recording any comments the student might have had.

misstable summarize

▷ Example 1

`misstable summarize` reports counts of missing values:

```
. misstable summarize
```

Variable	Obs=.	Obs>.	Obs<.	Obs<. Unique values	Obs<. Min	Obs<. Max
age	3		122	5	17	21
female	3		122	2	0	1
dept	9		116	4	1	4

Stata provides 27 different missing values, namely, `.`, `.a`, `.b`, ..., `.z`. The first of those, `.`, is often called system missing. The remaining missing values are called extended missings. The nonmissing and missing values are ordered *nonmissing* $<$ `.` $<$ `.a` $<$ `.b` $<\cdots<$ `.z`. Thus reported in the column "Obs=." are counts of system missing values; in the column "Obs>.", extended missing values; and in the column "Obs<.", nonmissing values.

The rightmost portion of the table is included to remind you how the variables are encoded.

Our data contain seven variables and yet `misstable` reported only three of them. The omitted variables contain no missing values or are string variables. Even if we specified the varlist explicitly, those variables would not appear in the table unless we specified the `all` option.

We can also create missing-value indicators for each of the variables above using the `generate()` option:

```
. quietly misstable summarize, generate(miss_)
. describe miss_*
```

variable name	storage type	display format	value label	variable label
miss_age	byte	%8.0g		(age>=.)
miss_female	byte	%8.0g		(female>=.)
miss_dept	byte	%8.0g		(dept>=.)

For each variable containing missing values, the `generate()` option creates a new binary variable containing `0` for complete observations and `1` for incomplete observations. In our example, three new missing-value indicators are generated, one for each of the incomplete variables `age`, `female`, and `dept`. The naming convention of `generate()` is to prefix the corresponding variable names with the specified *stub*, which is `miss_` in this example.

Missing-value indicators are useful, for example, for checking whether data are missing completely at random. They are also often used within the multiple-imputation context to identify the observed and imputed data; see [MI] **intro substantive** for a general introduction to multiple imputation. Within Stata's multiple-imputation commands, an incomplete value is identified by the system missing value, a dot. By default, `misstable summarize, generate()` marks the extended missing values as incomplete values, as well. You can use `exok` within `generate()` to treat extended missing values as complete when creating missing-value identifiers.

◁

misstable patterns

▷ Example 2

`misstable patterns` reports the pattern of missing values:

```
. misstable patterns
  Missing-value patterns
                |  Pattern
    Percent     |  1  2  3
----------------+---------
        93%     |  1  1  1
                |
         5      |  1  1  0
         2      |  0  0  0
----------------+---------
        100%    |
  Variables are  (1) age  (2) female  (3) dept
```

There are three patterns in these data: (1,1,1), (1,1,0), and (0,0,0). By default, the rows of the table are ordered by frequency. In larger tables that have more patterns, it is sometimes useful to order the rows by pattern. We could have obtained that by typing `mi misstable patterns, bypatterns`.

In a pattern, 1 indicates that all values of the variable are nonmissing and 0 indicates that all values are missing. Thus pattern (1,1,1) means no missing values, and 93% of our data have that pattern. There are two patterns in which variables are missing, (1,1,0) and (0,0,0). Pattern (1,1,0) means that `age` is nonmissing, `female` is nonmissing, and `dept` is missing. The order of the variables in the patterns appears in the key at the bottom of the table. Five percent of the observations have pattern (1,1,0). The remaining 2% have pattern (0,0,0), meaning that all three variables contain missing.

As with `misstable summarize`, only numeric variables that contain missing are listed, so had we typed `misstable patterns comments age female offcampus dept`, we still would have obtained the same table. Variables that are automatically omitted contain no missing values or are string variables.

The variables in the table are ordered from lowest to highest frequency of missing values, although you cannot see that from the information presented in the table. The variables are ordered this way even if you explicitly specify the varlist with a different ordering. Typing `misstable patterns dept female age` would produce the same table as above. Specify the `asis` option if you want the variables in the order in which you specify them.

You can obtain a dataset of the patterns by specifying the `replace` option:

```
. misstable patterns, replace clear
  Missing-value patterns
                |  Pattern
    Percent     |  1  2  3
----------------+---------
        93%     |  1  1  1
                |
         5      |  1  1  0
         2      |  0  0  0
----------------+---------
        100%    |
  Variables are  (1) age  (2) female  (3) dept
(summary data now in memory)
```

```
. list
```

	_freq	age	female	dept
1.	3	0	0	0
2.	6	1	1	0
3.	116	1	1	1

The differences between the dataset and the printed table are that 1) the dataset always records frequency and 2) the rows are reversed.

◁

misstable tree

▷ Example 3

`misstable tree` presents a tree view of the pattern of missing values:

```
. use http://www.stata-press.com/data/r12/studentsurvey, clear
(Student Survey)
. misstable tree, frequency
```

Nested pattern of missing values

dept	age	female
9	3	3
		0
	6	0
		6
116	0	0
		0
	116	0
		116

(number missing listed first)

In this example, we specified the `frequency` option to see the table in frequency rather than percentage terms. In the table, each column sums to the total number of observations in the data, 125. Variables are ordered from those with the most missing values to those with the least. Start with the first column. The `dept` variable is missing in 9 observations and, farther down, the table reports that it is not missing in 116 observations.

Go back to the first row and read across, but only to the second column. The `dept` variable is missing in 9 observations. Within those 9, `age` is missing in 3 of them and is not missing in the remaining 6. Reading down the second column, within the 116 observations that `dept` is not missing, `age` is missing in 0 and not missing in 116.

Reading straight across the first row again, `dept` is missing in 9 observations, and within the 9, `age` is missing in 3, and within the 3, `female` is also missing in 3. Skipping down just a little, within the 6 observations for which `dept` is missing and `age` is not missing, `female` is not missing, too.

◁

misstable nested

▷ Example 4

`misstable nested` lists the nesting rules that describe the missing-value pattern,

```
. misstable nested
     1.  female(3) <-> age(3) -> dept(9)
```

This line says that in observations in which `female` is missing, so is `age` missing, and vice versa, and in observations in which `age` (or `female`) is missing, so is `dept`. The numbers in parentheses are counts of the missing values. The `female` variable happens to be missing in 3 observations, and the same is true for `age`; the `dept` variable is missing in 9 observations. Thus `dept` is missing in the 3 observations for which `age` and `female` are missing, and in 6 more observations, too.

In these data, it turns out that the missing-value pattern can be summarized in one statement. In a larger dataset, you might see something like this:

```
. misstable nested
     1.  female(50) <-> age(50) -> dept(120)
     2.  female(50) -> m1(58)
     3.  offcampus(11)
```

`misstable nested` accounts for every missing value. In the above, in addition to `female <-> age -> dept`, we have that `female -> m1`, and we have `offcampus`, the last all by itself. The last line says that the 11 missing values in `offcampus` are not themselves nested in the missing value of any other variable, nor do they imply the missing values in another variable. In some datasets, all the statements will be of this last form.

In our data, however, we have one statement:

```
. misstable nested
     1.  female(3) <-> age(3) -> dept(9)
```

When the missing-value pattern can be summarized in one `misstable nested` statement, the pattern of missing values in the data is said to be monotone.

◁

Execution time of misstable nested

The execution time of `misstable nested` is affected little by the number of observations but can grow quickly with the number of variables, depending on the fraction of missing values within variable. The execution time of the example above, which has 3 variables containing missing, is instant. In worst-case scenarios, with 500 variables, the time might be 25 seconds; with 1,000 variables, the execution time might be closer to an hour.

In situations where `misstable nested` takes a long time to complete, it will produce thousands of rules that will defy interpretation. A 523-variable dataset we have seen ran in 20 seconds and produced 8,040 rules. Although we spotted a few rules in the output that did not surprise us, such as the year of the date being missing implied that the month and the day were also missing, mostly the output was not helpful.

If you have such a dataset, we recommend you run `misstable` on groups of variables that you have reason to believe the pattern of missing values might be related.

Saved results

misstable summarize saves the following values of the last variable summarized in r():

Scalars

r(N_eq_dot)	number of observations containing .
r(N_gt_dot)	number of observations containing .a, .b, ..., .z
r(N_lt_dot)	number of observations containing nonmissing
r(K_uniq)	number of unique, nonmissing values
r(min)	variable's minimum value
r(max)	variable's maximum value

Macros

r(vartype)	numeric, string, or none

r(K_uniq) contains . if the number of unique, nonmissing values is greater than 500. r(vartype) contains none if no variables are summarized, and in that case, the value of the scalars are all set to missing (.). Programmers intending to access results after misstable summarize should specify the all option.

misstable patterns saves the following in r():

Scalars

r(N_complete)	number of complete observations
r(N_incomplete)	number of incomplete observations
r(K)	number of patterns

Macros

r(vars)	variables used in order presented

r(N_complete) and r(N_incomplete) are defined with respect to the variables specified if variables were specified and otherwise, defined with respect to all the numeric variables in the dataset. r(N_complete) is the number of observations that contain no missing values.

misstable tree saves the following in r():

Macros

r(vars)	variables used in order presented

misstable nested saves the following in r():

Scalars

r(K)	number of statements

Macros

r(stmt1)	first statement
r(stmt2)	second statement
.	.
.	.
r(stmt`r(K)')	last statement
r(stmt1wc)	r(stmt1) with missing-value counts
r(vars)	variables considered

A statement is encoded "*varname*", "*varname op varname*", or "*varname op varname op varname*", and so on; *op* is either "->" or "<->".

Methods and formulas

misstable is implemented as an ado-file.

Title

mkspline — Linear and restricted cubic spline construction

Syntax

Linear spline with knots at specified points

```
mkspline newvar1 #1 [newvar2 #2 [...]] newvark = oldvar [if] [in] [, marginal
    displayknots]
```

Linear spline with knots equally spaced or at percentiles of data

```
mkspline stubname # = oldvar [if] [in] [weight] [, marginal pctile
    displayknots]
```

Restricted cubic spline

```
mkspline stubname = oldvar [if] [in] [weight], cubic [nknots(#) knots(numlist)
    displayknots]
```

`fweights` are allowed with the second and third syntax; see [U] **11.1.6 weight**.

Menu

Data > Create or change data > Other variable-creation commands > Linear and cubic spline construction

Description

`mkspline` creates variables containing a linear spline or a restricted cubic spline of *oldvar*.

In the first syntax, `mkspline` creates $newvar_1, \ldots, newvar_k$ containing a linear spline of *oldvar* with knots at the specified $\#_1, \ldots, \#_{k-1}$.

In the second syntax, `mkspline` creates # variables named *stubname*`1`, ..., *stubname*# containing a linear spline of *oldvar*. The knots are equally spaced over the range of *oldvar* or are placed at the percentiles of *oldvar*.

In the third syntax, `mkspline` creates variables containing a restricted cubic spline of *oldvar*. This is also known as a natural spline. The location and spacing of the knots is determined by the specification of the `nknots()` and `knots()` options.

Options

Options

`marginal` is allowed with the first or second syntax. It specifies that the new variables be constructed so that, when used in estimation, the coefficients represent the change in the slope from the preceding interval. The default is to construct the variables so that, when used in estimation, the coefficients measure the slopes for the interval.

`displayknots` displays the values of the knots that were used in creating the linear or restricted cubic spline.

`pctile` is allowed only with the second syntax. It specifies that the knots be placed at percentiles of the data rather than being equally spaced over the range.

`nknots(#)` is allowed only with the third syntax. It specifies the number of knots that are to be used for a restricted cubic spline. This number must be between 3 and 7 unless the knot locations are specified using `knots()`. The default number of knots is 5.

`knots(`*numlist*`)` is allowed only with the third syntax. It specifies the exact location of the knots to be used for a restricted cubic spline. The values of these knots must be given in increasing order. When this option is omitted, the default knot values are based on Harrell's recommended percentiles with the additional restriction that the smallest knot may not be less than the fifth-smallest value of *oldvar* and the largest knot may not be greater than the fifth-largest value of *oldvar*. If both `nknots()` and `knots()` are given, they must specify the same number of knots.

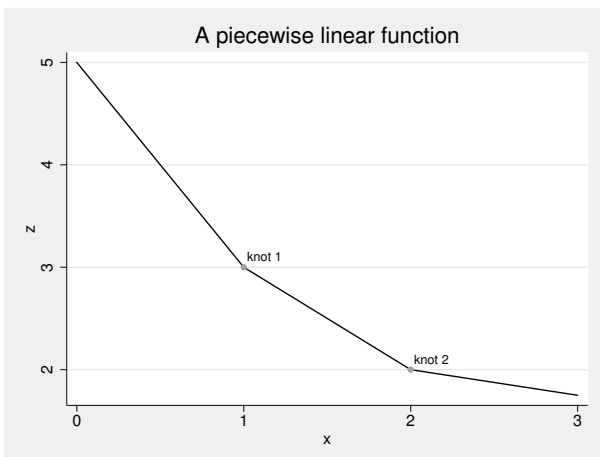
Remarks

Remarks are presented under the following headings:

Linear splines
Restricted cubic splines

Linear splines

Linear splines allow estimating the relationship between y and x as a piecewise linear function, which is a function composed of linear segments—straight lines. One linear segment represents the function for values of x below x_0, another linear segment handles values between x_0 and x_1, and so on. The linear segments are arranged so that they join at x_0, x_1, ..., which are called the knots. An example of a piecewise linear function is shown below.



Example 1

We wish to fit a model of log income on education and age by using a piecewise linear function for age:

$$\texttt{lninc} = b_0 + b_1\,\texttt{educ} + f(\texttt{age}) + u$$

The knots are to be placed at 10-year intervals: 20, 30, 40, 50, and 60.

```
. use http://www.stata-press.com/data/r12/mksp1
. mkspline age1 20 age2 30 age3 40 age4 50 age5 60 age6 = age, marginal
. regress lninc educ age1-age6
```
(*output omitted*)

Because we specified the `marginal` option, we could test whether the age effect is the same in the 30–40 and 40–50 intervals by asking whether the `age4` coefficient is zero. With the `marginal` option, coefficients measure the change in slope from the preceding group. Specifying `marginal` changes only the interpretation of the coefficients; the same model is fit in either case. Without the `marginal` option, the interpretation of the coefficients would have been

$$\frac{dy}{d\texttt{age}} = \begin{cases} a_1 & \text{if } \texttt{age} < 20 \\ a_2 & \text{if } 20 \le \texttt{age} < 30 \\ a_3 & \text{if } 30 \le \texttt{age} < 40 \\ a_4 & \text{if } 40 \le \texttt{age} < 50 \\ a_5 & \text{if } 50 \le \texttt{age} < 60 \\ a_6 & \text{otherwise} \end{cases}$$

With the `marginal` option, the interpretation is

$$\frac{dy}{d\texttt{age}} = \begin{cases} a_1 & \text{if } \texttt{age} < 20 \\ a_1 + a_2 & \text{if } 20 \le \texttt{age} < 30 \\ a_1 + a_2 + a_3 & \text{if } 30 \le \texttt{age} < 40 \\ a_1 + a_2 + a_3 + a_4 & \text{if } 40 \le \texttt{age} < 50 \\ a_1 + a_2 + a_3 + a_4 + a_5 & \text{if } 50 \le \texttt{age} < 60 \\ a_1 + a_2 + a_3 + a_4 + a_5 + a_6 & \text{otherwise} \end{cases}$$

◁

Example 2

Say that we have a binary outcome variable called `outcome`. We are beginning an analysis and wish to parameterize the effect of dosage on outcome. We wish to divide the data into five equal-width groups of dosage for the piecewise linear function.

```
. use http://www.stata-press.com/data/r12/mksp2
. mkspline dose 5 = dosage, displayknots
```

	knot1	knot2	knot3	knot4
dosage	20	40	60	80

```
. logistic outcome dose1-dose5
```
(*output omitted*)

`mkspline dose 5 = dosage` creates five variables—`dose1`, `dose2`, . . . , `dose5`—equally spacing the knots over the range of `dosage`. Because dosage varied between 0 and 100, the `mkspline` command above has the same effect as typing

```
. mkspline dose1 20 dose2 40 dose3 60 dose4 80 dose5 = dosage
```

The `pctile` option sets the knots to divide the data into five equal sample-size groups rather than five equal-width ranges. Typing

```
. mkspline pctdose 5 = dosage, pctile displayknots
```

	knot1	knot2	knot3	knot4
dosage	16	36.4	55.6	82

places the knots at the 20th, 40th, 60th, and 80th percentiles of the data.

◁

Restricted cubic splines

A linear spline can be used to fit many functions well. However, a restricted cubic spline may be a better choice than a linear spline when working with a very curved function. When using a restricted cubic spline, one obtains a continuous smooth function that is linear before the first knot, a piecewise cubic polynomial between adjacent knots, and linear again after the last knot.

▷ Example 3

Returning to the data from example 1, we may feel that a curved function is a better fit. First, we will use the `knots()` option to specify the five knots that we used previously.

```
. use http://www.stata-press.com/data/r12/mksp1, clear
. mkspline agesp = age, cubic knots(20 30 40 50 60)
. regress lninc educ agesp*
```
(*output omitted*)

Harrell (2001, 23) recommends placing knots at equally spaced percentiles of the original variable's marginal distribution. If we do not specify the `knots()` option, variables will be created containing a restricted cubic spline with five knots determined by Harrell's default percentiles.

```
. use http://www.stata-press.com/data/r12/mksp1, clear
. mkspline agesp = age, cubic displayknots
. regress lninc educ agesp*
```
(*output omitted*)

◁

Methods and formulas

`mkspline` is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Linear splines
Restricted cubic splines

Linear splines

Let V_i, $i = 1, \ldots, n$, be the variables to be created; k_i, $i = 1, \ldots, n-1$, be the corresponding knots; and $\mathcal{V}$ be the original variable (the command is `mkspline` V_1 k_1 V_2 k_2 ... V_n `=` $\mathcal{V}$). Then

$$V_1 = \min(\mathcal{V}, k_1)$$
$$V_i = \max\Big\{\min(\mathcal{V}, k_i), k_{i-1}\Big\} - k_{i-1} \quad i = 2, \ldots, n$$

If the `marginal` option is specified, the definitions are

$$V_1 = \mathcal{V}$$
$$V_i = \max(0, \mathcal{V} - k_{i-1}) \quad i = 2, \ldots, n$$

In the second syntax, `mkspline` *stubname* `#` `=` $\mathcal{V}$, so let m and M be the minimum and maximum of $\mathcal{V}$. Without the `pctile` option, knots are set at $m + (M - m)(i/n)$ for $i = 1, \ldots, n-1$. If `pctile` is specified, knots are set at the $100(i/n)$ percentiles, for $i = 1, \ldots, n-1$. Percentiles are calculated by `centile`; see [R] **centile**.

Restricted cubic splines

Let k_i, $i = 1, \ldots, n$, be the knot values; V_i, $i = 1, \ldots, n-1$, be the variables to be created; and $\mathcal{V}$ be the original variable. Then

$$V_1 = \mathcal{V}$$
$$V_{i+1} = \frac{(\mathcal{V} - k_i)_+^3 - (k_n - k_{n-1})^{-1}\{(\mathcal{V} - k_{n-1})_+^3(k_n - k_i) - (\mathcal{V} - k_n)_+^3(k_{n-1} - k_i)\}}{(k_n - k_1)^2}$$
$$i = 1, \ldots, n-2$$

where

$$(u)_+ = \begin{cases} u, \text{ if } & u > 0 \\ 0, \text{ if } & u \leq 0 \end{cases}$$

Without the `knots()` option, the locations of the knots are determined by the percentiles recommended in Harrell (2001, 23). These percentiles are based on the chosen number of knots as follows:

No. of knots	Percentiles						
3	10	50	90				
4	5	35	65	95			
5	5	27.5	50	72.5	95		
6	5	23	41	59	77	95	
7	2.5	18.33	34.17	50	65.83	81.67	97.5

Harrell provides default percentiles when the number of knots is between 3 and 7. When using a number of knots outside this range, the location of the knots must be specified in `knots()`.

Acknowledgment

The restricted cubic spline portion of `mkspline` is based on the `rc_spline` command by William Dupont.

Title

ml — Maximum likelihood estimation

Syntax

ml model in interactive mode

`ml model` *method progname eq* [*eq* ...] [*if*] [*in*] [*weight*]
[, *model_options* `svy` *diparm_options*]

`ml model` *method funcname*`()` *eq* [*eq* ...] [*if*] [*in*] [*weight*]
[, *model_options* `svy` *diparm_options*]

ml model in noninteractive mode

`ml model` *method progname eq* [*eq* ...] [*if*] [*in*] [*weight*] , `maximize`
[*model_options* `svy` *diparm_options noninteractive_options*]

`ml model` *method funcname*`()` *eq* [*eq* ...] [*if*] [*in*] [*weight*] , `maximize`
[*model_options* `svy` *diparm_options noninteractive_options*]

Noninteractive mode is invoked by specifying the `maximize` option. Use `maximize` when `ml` will be used as a subroutine of another ado-file or program and you want to carry forth the problem, from definition to posting of results, in one command.

`ml clear`

`ml query`

`ml check`

`ml search` [[`/`]*eqname*[`:`] $\#_{lb}$ $\#_{ub}$] [...] [, *search_options*]

`ml plot` [*eqname*`:`]*name* [# [# [#]]] [, `saving(`*filename*[, `replace`]`)`]

`ml init` { [*eqname*`:`]*name*`=#` | `/`*eqname*`=#` } [...]

`ml init` # [# ...] , `copy`

`ml init` *matname* [, `copy skip`]

`ml report`

`ml trace` { `on` | `off` }

`ml count` [`clear` | `on` | `off`]

`ml maximize` [, *ml_maximize_options display_options eform_option*]

```
ml graph    [#] [, saving(filename[, replace])]

ml display  [, display_options eform_option]

ml footnote

ml score newvar [if] [in] [, equation(eqname) missing]

ml score newvarlist [if] [in] [, missing]

ml score [type] stub* [if] [in] [, missing]
```

where *method* is one of

lf	d0	lf0	gf0
	d1	lf1	
	d1debug	lf1debug	
	d2	lf2	
	d2debug	lf2debug	

or *method* can be specified using one of the longer, more descriptive names

method	Longer name
lf	linearform
d0	derivative0
d1	derivative1
d1debug	derivative1debug
d2	derivative2
d2debug	derivative2debug
lf0	linearform0
lf1	linearform1
lf1debug	linearform1debug
lf2	linearform2
lf2debug	linearform2debug
gf0	generalform0

eq is the equation to be estimated, enclosed in parentheses, and optionally with a name to be given to the equation, preceded by a colon,

(\[*eqname*:\] \[$varlist_y$ =\] \[$varlist_x$\] \[, *eq_options*\])

or *eq* is the name of a parameter, such as sigma, with a slash in front

/*eqname* which is equivalent to (*eqname*:)

and *diparm_options* is one or more `diparm(`*diparm_args*`)` options where *diparm_args* is either `__sep__` or anything accepted by the "undocumented" `_diparm` command; see help `_diparm`.

eq_options	Description
noconstant	do not include an intercept in the equation
offset(*varname*$_o$)	include *varname*$_o$ in model with coefficient constrained to 1
exposure(*varname*$_e$)	include ln(*varname*$_e$) in model with coefficient constrained to 1

model_options	Description
`group(`*varname*`)`	use *varname* to identify groups
`vce(`*vcetype*`)`	*vcetype* may be `robust`, `cluster` *clustvar*, `oim`, or `opg`
`constraints(`*numlist*`)`	constraints by number to be applied
`constraints(`*matname*`)`	matrix that contains the constraints to be applied
`nocnsnotes`	do not display notes when constraints are dropped
`title(`*string*`)`	place a title on the estimation output
`nopreserve`	do not preserve the estimation subsample in memory
`collinear`	keep collinear variables within equations
`missing`	keep observations containing variables with missing values
`lf0(`$\#_k$ $\#_{ll}$`)`	number of parameters and log-likelihood value of the constant-only model
`continue`	specifies that a model has been fit and sets the initial values $\mathbf{b}_0$ for the model to be fit based on those results
`waldtest(#)`	perform a Wald test; see *Options for use with ml model in interactive or noninteractive mode* below
`obs(#)`	number of observations
`crittype(`*string*`)`	describe the criterion optimized by `ml`
`subpop(`*varname*`)`	compute estimates for the single subpopulation
`nosvyadjust`	carry out Wald test as $W/k \sim F(k,d)$
`technique(nr)`	Stata's modified Newton–Raphson (NR) algorithm
`technique(bhhh)`	Berndt–Hall–Hall–Hausman (BHHH) algorithm
`technique(dfp)`	Davidon–Fletcher–Powell (DFP) algorithm
`technique(bfgs)`	Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm

noninteractive_options	Description
`init(`*ml_init_args*`)`	set the initial values $\mathbf{b}_0$
`search(on)`	equivalent to `ml search, repeat(0)`; the default
`search(norescale)`	equivalent to `ml search, repeat(0) norescale`
`search(quietly)`	same as `search(on)`, except that output is suppressed
`search(off)`	prevents calling `ml search`
`repeat(#)`	`ml search`'s `repeat()` option; see below
`bounds(`*ml_search_bounds*`)`	specify bounds for `ml search`
`nowarning`	suppress "convergence not achieved" message of `iterate(0)`
`novce`	substitute the zero matrix for the variance matrix
`negh`	indicates that the evaluator returns the negative Hessian matrix
`score(`*newvars*`)`	new variables containing the contribution to the score
maximize_options	control the maximization process; seldom used

search_options	Description
repeat(#)	number of random attempts to find better initial-value vector; default is repeat(10) in interactive mode and repeat(0) in noninteractive mode
restart	use random actions to find starting values; not recommended
norescale	do not rescale to improve parameter vector; not recommended
maximize_options	control the maximization process; seldom used

ml_maximize_options	Description
nowarning	suppress "convergence not achieved" message of iterate(0)
novce	substitute the zero matrix for the variance matrix
negh	indicates that the evaluator returns the negative Hessian matrix
score(*newvars* | *stub**)	new variables containing the contribution to the score
nooutput	suppress display of final results
noclear	do not clear ml problem definition after model has converged
maximize_options	control the maximization process; seldom used

display_options	Description
noheader	suppress header display above the coefficient table
nofootnote	suppress footnote display below the coefficient table
level(#)	set confidence level; default is level(95)
first	display coefficient table reporting results for first equation only
neq(#)	display coefficient table reporting first # equations
showeqns	display equation names in the coefficient table
plus	display coefficient table ending in dashes–plus-sign–dashes
nocnsreport	suppress constraints display above the coefficient table
noomitted	suppress display of omitted variables
vsquish	suppress blank space separating factor-variable terms or time-series–operated variables from other variables
noemptycells	suppress empty cells for interactions of factor variables
baselevels	report base levels of factor variables and interactions
allbaselevels	display all base levels of factor variables and interactions
cformat(%*fmt*)	format the coefficients, standard errors, and confidence limits in the coefficient table
pformat(%*fmt*)	format the p-values in the coefficient table
sformat(%*fmt*)	format the test statistics in the coefficient table
nolstretch	do not automatically widen the coefficient table to accommodate longer variable names
coeflegend	display legend instead of statistics

eform_option	Description
eform(*string*)	display exponentiated coefficients; column title is "*string*"
eform	display exponentiated coefficients; column title is "exp(b)"
hr	report hazard ratios
shr	report subhazard ratios
irr	report incidence-rate ratios
or	report odds ratios
rrr	report relative-risk ratios

fweights, aweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**. With all but method lf, you must write your likelihood-evaluation program carefully if pweights are to be specified, and pweights may not be specified with method d0, d1, d1debug, d2, or d2debug. See Gould, Pitblado, and Poi (2010, chap. 6) for details.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

To redisplay results, type ml display.

Syntax of subroutines for use by evaluator programs

```
mleval      newvar = vecname [ , eq(#) ]
mleval      scalarname = vecname , scalar [ eq(#) ]
mlsum       scalarname_lnf = exp [ if ] [ , noweight ]
mlvecsum    scalarname_lnf rowvecname = exp [ if ] [ , eq(#) ]
mlmatsum    scalarname_lnf matrixname = exp [ if ] [ , eq(#[,#]) ]
mlmatbysum  scalarname_lnf matrixname varname_a varname_b [ varname_c ] [ if ] ,
                by(varname) [ eq(#[,#]) ]
```

Syntax of user-written evaluator

Summary of notation

The log-likelihood function is $\ln L(\theta_{1j}, \theta_{2j}, \ldots, \theta_{Ej})$, where $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$, $j = 1, \ldots, N$ indexes observations, and $i = 1, \ldots, E$ indexes the linear equations defined by ml model. If the likelihood satisfies the linear-form restrictions, it can be decomposed as $\ln L = \sum_{j=1}^{N} \ln \ell(\theta_{1j}, \theta_{2j}, \ldots, \theta_{Ej})$.

Method-lf evaluators

```
program progname
        version 12
        args lnfj theta1 theta2 ...
        // if you need to create any intermediate results:
        tempvar tmp1 tmp2 ...
        quietly gen double `tmp1' = ...
        ...
        quietly replace `lnfj' = ...
end
```

where

`'lnfj'`	variable to be filled in with observation-by-observation values of $\ln\ell_j$
`'theta1'`	variable containing evaluation of first equation $\theta_{1j}=\mathbf{x}_{1j}\mathbf{b}_1$
`'theta2'`	variable containing evaluation of second equation $\theta_{2j}=\mathbf{x}_{2j}\mathbf{b}_2$
`...`	

Method-d0 evaluators

```
program progname
        version 12
        args todo b lnf
        tempvar theta1 theta2 ...
        mleval 'theta1' = 'b', eq(1)
        mleval 'theta2' = 'b', eq(2) // if there is a θ2
        ...
        // if you need to create any intermediate results:
        tempvar tmp1 tmp2 ...
        gen double 'tmp1' = ...
        ...
        mlsum 'lnf' = ...
end
```

where

`'todo'`	always contains `0` (may be ignored)
`'b'`	full parameter row vector $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,...,\mathbf{b}_E)$
`'lnf'`	scalar to be filled in with overall $\ln L$

Method-d1 evaluators

```
program progname
        version 12
        args todo b lnf g
        tempvar theta1 theta2 ...
        mleval 'theta1' = 'b', eq(1)
        mleval 'theta2' = 'b', eq(2) // if there is a θ2
        ...
        // if you need to create any intermediate results:
        tempvar tmp1 tmp2 ...
        gen double 'tmp1' = ...
        ...
        mlsum 'lnf' = ...
        if ('todo'==0 | 'lnf'>=.) exit
        tempname d1 d2 ...
        mlvecsum 'lnf' 'd1' = formula for ∂lnℓj/∂θ1j, eq(1)
        mlvecsum 'lnf' 'd2' = formula for ∂lnℓj/∂θ2j, eq(2)
        ...
        matrix 'g' = ('d1','d2', ... )
end
```

where

`'todo'`	contains `0` or `1` `0`⇒`'lnf'` to be filled in; `1`⇒`'lnf'` and `'g'` to be filled in
`'b'`	full parameter row vector $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,...,\mathbf{b}_E)$
`'lnf'`	scalar to be filled in with overall $\ln L$
`'g'`	row vector to be filled in with overall $\mathbf{g}=\partial\ln L/\partial\mathbf{b}$

Method-d2 evaluators

```
program progname
        version 12
        args todo b lnf g H
        tempvar theta1 theta2 ...
        mleval `theta1' = `b', eq(1)
        mleval `theta2' = `b', eq(2) // if there is a θ2
        ...
        // if you need to create any intermediate results:
        tempvar tmp1 tmp2 ...
        gen double `tmp1' = ...
        ...
        mlsum `lnf' = ...
        if (`todo'==0 | `lnf'>=.) exit
        tempname d1 d2 ...
        mlvecsum `lnf' `d1' = formula for ∂lnℓj/∂θ1j, eq(1)

        gen double 'tmp1' = ...
        ...
        quietly replace 'lnfj' = ...
end
```

where

`'todo'`	always contains `0` (may be ignored)
`'b'`	full parameter row vector $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,...,\mathbf{b}_E)$
`'lnfj'`	variable to be filled in with the values of the log-likelihood $\ln\ell_j$

Global macros for use by all evaluators

`$ML_y1`	name of first dependent variable
`$ML_y2`	name of second dependent variable, if any
...	
`$ML_samp`	variable containing 1 if observation to be used; 0 otherwise
`$ML_w`	variable containing weight associated with observation or 1 if no weights specified

Method-lf evaluators can ignore `$ML_samp`, but restricting calculations to the `$ML_samp==1` subsample will speed execution. Method-lf evaluators must ignore `$ML_w`; application of weights is handled by the method itself.

Methods d0, d1, d2, lf0, lf1, lf2, and gf0 can ignore `$ML_samp` as long as `ml model`'s `nopreserve` option is not specified. These methods will run more quickly if `nopreserve` is specified. These evaluators can ignore `$ML_w` only if they use `mlsum`, `mlvecsum`, `mlmatsum`, and `mlmatbysum` to produce all final results.

Description

`ml model` defines the current problem.

`ml clear` clears the current problem definition. This command is rarely used because when you type `ml model`, any previous problem is automatically cleared.

`ml query` displays a description of the current problem.

`ml check` verifies that the log-likelihood evaluator you have written works. We strongly recommend using this command.

`ml search` searches for (better) initial values. We recommend using this command.

`ml plot` provides a graphical way of searching for (better) initial values.

`ml init` provides a way to specify initial values.

`ml report` reports $\ln L$'s values, gradient, and Hessian at the initial values or current parameter estimates, $\mathbf{b}_0$.

`ml trace` traces the execution of the user-defined log-likelihood evaluation program.

`ml count` counts the number of times the user-defined log-likelihood evaluation program is called; this command is seldom used. `ml count clear` clears the counter. `ml count on` turns on the counter. `ml count` without arguments reports the current values of the counter. `ml count off` stops counting calls.

`ml maximize` maximizes the likelihood function and reports results. Once `ml maximize` has successfully completed, the previously mentioned `ml` commands may no longer be used unless `noclear` is specified. `ml graph` and `ml display` may be used whether or not `noclear` is specified.

`ml graph` graphs the log-likelihood values against the iteration number.

`ml display` redisplays results.

`ml footnote` displays a warning message when the model did not converge within the specified number of iterations.

`ml score` creates new variables containing the equation-level scores. The variables generated by `ml score` are equivalent to those generated by specifying the `score()` option of `ml maximize` (and `ml model ..., ... maximize`).

progname is the name of a Stata program you write to evaluate the log-likelihood function.

funcname`()` is the name of a Mata function you write to evaluate the log-likelihood function.

In this documentation, *progname* and *funcname*`()` are referred to as the user-written evaluator, the likelihood evaluator, or sometimes simply as the evaluator. The program you write is written in the style required by the method you choose. The methods are lf, d0, d1, d2, lf0, lf1, lf2, and gf0. Thus, if you choose to use method lf, your program is called a method-lf evaluator.

Method-lf evaluators are required to evaluate the observation-by-observation log likelihood $\ln \ell_j$, $j = 1, \ldots, N$.

Method-d0 evaluators are required to evaluate the overall log likelihood $\ln L$. Method-d1 evaluators are required to evaluate the overall log likelihood and its gradient vector $\mathbf{g} = \partial \ln L/\partial \mathbf{b}$. Method-d2 evaluators are required to evaluate the overall log likelihood, its gradient, and its Hessian matrix $H = \partial^2 \ln L/\partial \mathbf{b} \partial \mathbf{b}'$.

Method-lf0 evaluators are required to evaluate the observation-by-observation log likelihood $\ln \ell_j$, $j = 1, \ldots, N$. Method-lf1 evaluators are required to evaluate the observation-by-observation log likelihood and its equation-level scores $g_{ji} = \partial \ln \ell/\partial \mathbf{x}_{ji}\mathbf{b}_i$. Method-lf2 evaluators are required to evaluate the observation-by-observation log likelihood, its equation-level scores, and its Hessian matrix $H = \partial^2 \ln \ell/\partial \mathbf{b} \partial \mathbf{b}'$.

Method-gf0 evaluators are required to evaluate the summable pieces of the log likelihood $\ln \ell_k$, $k = 1, \ldots, K$.

`mleval` is a subroutine used by evaluators of methods d0, d1, d2, lf0, lf1, lf2, and gf0 to evaluate the coefficient vector, $\mathbf{b}$, that they are passed.

`mlsum` is a subroutine used by evaluators of methods d0, d1, and d2 to define the value, $\ln L$, that is to be returned.

`mlvecsum` is a subroutine used by evaluators of methods d1 and d2 to define the gradient vector, $\mathbf{g}$, that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatsum` is a subroutine used by evaluators of methods d2 and lf2 to define the Hessian matrix, $\mathbf{H}$, that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatbysum` is a subroutine used by evaluator of method d2 to help define the Hessian matrix, $\mathbf{H}$, that is to be returned. It is suitable for use when the likelihood function contains terms made up of grouped sums, such as in panel-data models. For such models, use `mlmatsum` to compute the observation-level outer products and `mlmatbysum` to compute the group-level outer products. `mlmatbysum` requires that the data be sorted by the variable identified in the `by()` option.

Options for use with ml model in interactive or noninteractive mode

`group(`*varname*`)` specifies the numeric variable that identifies groups. This option is typically used to identify panels for panel-data models.

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification, that allow for intragroup correlation, and that are derived from asymptotic theory; see [R] ***vce_option***.

`vce(robust)`, `vce(cluster` *clustvar*`)`, `pweight`, and `svy` will work with evaluators of methods lf, lf0, lf1, lf2, and gf0; all you need do is specify them.

These options will not work with evaluators of methods d0, d1, or d2, and specifying these options will produce an error message.

`constraints(`*numlist* | *matname*`)` specifies the linear constraints to be applied during estimation. `constraints(`*numlist*`)` specifies the constraints by number. Constraints are defined by using the `constraint` command; see [R] **constraint**. `constraint(`*matname*`)` specifies a matrix that contains the constraints.

`nocnsnotes` prevents notes from being displayed when constraints are dropped. A constraint will be dropped if it is inconsistent, contradicts other constraints, or causes some other error when the constraint matrix is being built. Constraints are checked in the order in which they are specified.

`title(`*string*`)` specifies the title for the estimation output when results are complete.

`nopreserve` specifies that `ml` need not ensure that only the estimation subsample is in memory when the user-written likelihood evaluator is called. `nopreserve` is irrelevant when you use method lf.

For the other methods, if `nopreserve` is not specified, `ml` saves the data in a file (preserves the original dataset) and drops the irrelevant observations before calling the user-written evaluator. This way, even if the evaluator does not restrict its attentions to the `$ML_samp==1` subsample, results will still be correct. Later, `ml` automatically restores the original dataset.

`ml` need not go through these machinations for method lf because the user-written evaluator calculates observation-by-observation values, and `ml` itself sums the components.

`ml` goes through these machinations if and only if the estimation sample is a subsample of the data in memory. If the estimation sample includes every observation in memory, `ml` does not preserve the original dataset. Thus programmers must not alter the original dataset unless they `preserve` the data themselves.

We recommend that interactive users of `ml` not specify `nopreserve`; the speed gain is not worth the possibility of getting incorrect results.

We recommend that programmers specify nopreserve, but only after verifying that their evaluator really does restrict its attentions solely to the $ML_samp==1 subsample.

collinear specifies that ml not remove the collinear variables within equations. There is no reason to leave collinear variables in place, but this option is of interest to programmers who, in their code, have already removed collinear variables and do not want ml to waste computer time checking again.

missing specifies that observations containing variables with missing values not be eliminated from the estimation sample. There are two reasons you might want to specify missing:

Programmers may wish to specify missing because, in other parts of their code, they have already eliminated observations with missing values and do not want ml to waste computer time looking again.

You may wish to specify missing if your model explicitly deals with missing values. Stata's heckman command is a good example of this. In such cases, there will be observations where missing values are allowed and other observations where they are not—where their presence should cause the observation to be eliminated. If you specify missing, it is your responsibility to specify an if *exp* that eliminates the irrelevant observations.

lf0($\#_k$ $\#_{ll}$) is typically used by programmers. It specifies the number of parameters and log-likelihood value of the constant-only model so that ml can report a likelihood-ratio test rather than a Wald test. These values may have been analytically determined, or they may have been determined by a previous fitting of the constant-only model on the estimation sample.

Also see the continue option directly below.

If you specify lf0(), it must be safe for you to specify the missing option, too, else how did you calculate the log likelihood for the constant-only model on the same sample? You must have identified the estimation sample, and done so correctly, so there is no reason for ml to waste time rechecking your results. All of which is to say, do not specify lf0() unless you are certain your code identifies the estimation sample correctly.

lf0(), even if specified, is ignored if vce(robust), vce(cluster *clustvar*), pweight, or svy is specified because, in that case, a likelihood-ratio test would be inappropriate.

continue is typically specified by programmers and does two things:

First, it specifies that a model has just been fit by either ml or some other estimation command, such as logit, and that the likelihood value stored in e(ll) and the number of parameters stored in e(b) as of that instant are the relevant values of the constant-only model. The current value of the log likelihood is used to present a likelihood-ratio test unless vce(robust), vce(cluster *clustvar*), pweight, svy, or constraints() is specified. A likelihood-ratio test is inappropriate when vce(robust), vce(cluster *clustvar*), pweight, or svy is specified. We suggest using lrtest when constraints() is specified; see [R] **lrtest**.

Second, continue sets the initial values, $\mathbf{b}_0$, for the model about to be fit according to the e(b) currently stored.

The comments made about specifying missing with lf0() apply equally well here.

waldtest(#) is typically specified by programmers. By default, ml presents a Wald test, but that is overridden if the lf0() or continue option is specified. A Wald test is performed if vce(robust), vce(cluster *clustvar*), or pweight is specified.

waldtest(0) prevents even the Wald test from being reported.

waldtest(-1) is the default. It specifies that a Wald test be performed by constraining all coefficients except the intercept to 0 in the first equation. Remaining equations are to be unconstrained.

A Wald test is performed if neither `lf0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweight` was specified.

`waldtest(`k`)` for $k \leq -1$ specifies that a Wald test be performed by constraining all coefficients except intercepts to 0 in the first $|k|$ equations; remaining equations are to be unconstrained. A Wald test is performed if neither `lf0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweight` was specified.

`waldtest(`k`)` for $k \geq 1$ works like the options above, except that it forces a Wald test to be reported even if the information to perform the likelihood-ratio test is available and even if none of `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweight` was specified. `waldtest(`k`)`, $k \geq 1$, may not be specified with `lf0()`.

`obs(#)` is used mostly by programmers. It specifies that the number of observations reported and ultimately stored in `e(N)` be `#`. Ordinarily, `ml` works that out for itself. Programmers may want to specify this option when, for the likelihood evaluator to work for N observations, they first had to modify the dataset so that it contained a different number of observations.

`crittype(`*string*`)` is used mostly by programmers. It allows programmers to supply a string (up to 32 characters long) that describes the criterion that is being optimized by `ml`. The default is `"log likelihood"` for nonrobust and `"log pseudolikelihood"` for robust estimation.

`svy` indicates that `ml` is to pick up the `svy` settings set by `svyset` and use the robust variance estimator. This option requires the data to be `svyset`; see [SVY] **svyset**. `svy` may not be specified with `vce()` or *weights*.

`subpop(`*varname*`)` specifies that estimates be computed for the single subpopulation defined by the observations for which *varname* $\neq 0$. Typically, *varname* $= 1$ defines the subpopulation, and *varname* $= 0$ indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, *varname* should be set to missing (‘`.`’). This option requires the `svy` option.

`nosvyadjust` specifies that the model Wald test be carried out as $W/k \sim F(k, d)$, where W is the Wald test statistic, k is the number of terms in the model excluding the constant term, d is the total number of sampled PSUs minus the total number of strata, and $F(k, d)$ is an F distribution with k numerator degrees of freedom and d denominator degrees of freedom. By default, an adjusted Wald test is conducted: $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$. See Korn and Graubard (1990) for a discussion of the Wald test and the adjustments thereof. This option requires the `svy` option.

`technique(`*algorithm_spec*`)` specifies how the likelihood function is to be maximized. The following algorithms are currently implemented in `ml`. For details, see Gould, Pitblado, and Poi (2010).

`technique(nr)` specifies Stata’s modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfp)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, `ml` will use an algorithm for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations using the BHHH algorithm, followed by 1,000 iterations using the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until reaching the maximum number of iterations.

Options for use with ml model in noninteractive mode

The following extra options are for use with `ml model` in noninteractive mode. Noninteractive mode is for programmers who use `ml` as a subroutine and want to issue one command that will carry forth the estimation from start to finish.

`maximize` is required. It specifies noninteractive mode.

`init(`*ml_init_args*`)` sets the initial values, $\mathbf{b}_0$. *ml_init_args* are whatever you would type after the `ml init` command.

`search(on | norescale | quietly | off)` specifies whether `ml search` is to be used to improve the initial values. `search(on)` is the default and is equivalent to separately running `ml search, repeat(0)`. `search(norescale)` is equivalent to separately running `ml search, repeat(0) norescale`. `search(quietly)` is equivalent to `search(on)`, except that it suppresses `ml search`'s output. `search(off)` prevents calling `ml search`.

`repeat(#)` is `ml search`'s `repeat()` option. `repeat(0)` is the default.

`bounds(`*ml_search_bounds*`)` specifies the search bounds. *ml_search_bounds* is specified as

$$[\,\textit{eqn\_name}\,]\ \textit{lower\_bound upper\_bound}\ \ldots\ [\,\textit{eqn\_name}\,]\ \textit{lower\_bound upper\_bound}$$

for instance, `bounds(100 100 lnsigma 0 10)`. The `ml model` command issues `ml search` *ml_search_bounds*`, repeat(#)`. Specifying search bounds is optional.

`nowarning`, `novce`, `negh`, and `score()` are `ml maximize`'s equivalent options.

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Options for use when specifying equations

`noconstant` specifies that the equation not include an intercept.

`offset(`*varname*$_o$`)` specifies that the equation be $\mathbf{xb} + $ *varname*$_o$—that it include *varname*$_o$ with coefficient constrained to be 1.

`exposure(`*varname*$_e$`)` is an alternative to `offset(`*varname*$_o$`)`; it specifies that the equation be $\mathbf{xb} + \ln($*varname*$_e)$. The equation is to include $\ln($*varname*$_e)$ with coefficient constrained to be 1.

Options for use with ml search

`repeat(#)` specifies the number of random attempts that are to be made to find a better initial-value vector. The default is `repeat(10)`.

`repeat(0)` specifies that no random attempts be made. More precisely, `repeat(0)` specifies that no random attempts be made if the first initial-value vector is a feasible starting point. If it is not, `ml search` will make random attempts, even if you specify `repeat(0)`, because it has no alternative. The `repeat()` option refers to the number of random attempts to be made to improve the initial values. When the initial starting value vector is not feasible, `ml search` will make up to 1,000 random attempts to find starting values. It stops when it finds one set of values that works and then moves into its improve-initial-values logic.

`repeat(`k`)`, $k > 0$, specifies the number of random attempts to be made to improve the initial values.

`restart` specifies that random actions be taken to obtain starting values and that the resulting starting values not be a deterministic function of the current values. Generally, you should not specify this option because, with `restart`, `ml search` intentionally does not produce as good a set of starting values as it could. `restart` is included for use by the optimizer when it gets into serious trouble. The random actions ensure that the optimizer and `ml search`, working together, do not cause an endless loop.

`restart` implies `norescale`, which is why we recommend that you do not specify `restart`. In testing, sometimes `rescale` worked so well that, even after randomization, the rescaler would bring the starting values right back to where they had been the first time and thus defeat the intended randomization.

`norescale` specifies that `ml search` not engage in its rescaling actions to improve the parameter vector. We do not recommend specifying this option because rescaling tends to work so well.

maximize_options: [`no`]`log` and `trace`; see [R] **maximize**. These options are seldom used.

Option for use with ml plot

`saving(`*filename*[`, replace`]`)` specifies that the graph be saved in *filename*`.gph`. See [G-3] ***saving_option***.

Options for use with ml init

`copy` specifies that the list of numbers or the initialization vector be copied into the initial-value vector by position rather than by name.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

Options for use with ml maximize

`nowarning` is allowed only with `iterate(0)`. `nowarning` suppresses the "convergence not achieved" message. Programmers might specify `iterate(0) nowarning` when they have a vector $\mathbf{b}$ already containing the final estimates and want `ml` to calculate the variance matrix and postestimation results. Then specify `init(b) search(off) iterate(0) nowarning nolog`.

`novce` is allowed only with `iterate(0)`. `novce` substitutes the zero matrix for the variance matrix, which in effect posts estimation results as fixed constants.

`negh` indicates that the evaluator returns the negative Hessian matrix. By default, `ml` assumes d2 and lf2 evaluators return the Hessian matrix.

`score(`*newvars* | *stub*`*)` creates new variables containing the contributions to the score for each equation and ancillary parameter in the model; see [U] **20.21 Obtaining scores**.

If `score(`*newvars*`)` is specified, the *newvars* must contain k new variables. For evaluators of methods lf, lf0, lf1, and lf2, k is the number of equations. For evaluators of method gf0, k is the number of parameters. If `score(`*stub*`*)` is specified, variables named *stub*`1`, *stub*`2`, ..., *stub*`k` are created.

For evaluators of methods lf, lf0, lf1, and lf2, the first variable contains $\partial \ln \ell_j / \partial(\mathbf{x}_{1j}\mathbf{b}_1)$, the second variable contains $\partial \ln \ell_j / \partial(\mathbf{x}_{2j}\mathbf{b}_2)$, and so on.

For evaluators of method gf0, the first variable contains $\partial \ln \ell_j / \partial \mathbf{b}_1$, the second variable contains $\partial \ln \ell_j / \partial \mathbf{b}_2$, and so on.

`nooutput` suppresses display of results. This option is different from prefixing `ml maximize` with `quietly` in that the iteration log is still displayed (assuming that `nolog` is not specified).

`noclear` specifies that the ml problem definition not be cleared after the model has converged. Perhaps you are having convergence problems and intend to run the model to convergence. If so, use `ml search` to see if those values can be improved, and then restart the estimation.

maximize_options: `difficult`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`; see [R] **maximize**. These options are seldom used.

display_options; see *Options for use with ml display* below.

eform_option; see *Options for use with ml display* below.

Option for use with ml graph

`saving(`*filename*`[ , replace])` specifies that the graph be saved in *filename*`.gph`. See [G-3] ***saving_option***.

Options for use with ml display

`noheader` suppresses the header display above the coefficient table that displays the final log-likelihood value, the number of observations, and the model significance test.

`nofootnote` suppresses the footnote display below the coefficient table, which displays a warning if the model fit did not converge within the specified number of iterations. Use `ml footnote` to display the warning if 1) you add to the coefficient table using the `plus` option or 2) you have your own footnotes and want the warning to be last.

`level(#)` is the standard confidence-level option. It specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`first` displays a coefficient table reporting results for the first equation only, and the report makes it appear that the first equation is the only equation. This option is used by programmers who estimate ancillary parameters in the second and subsequent equations and who wish to report the values of such parameters themselves.

`neq(#)` is an alternative to `first`. `neq(#)` displays a coefficient table reporting results for the first # equations. This option is used by programmers who estimate ancillary parameters in the $\# + 1$ and subsequent equations and who wish to report the values of such parameters themselves.

`showeqns` is a seldom-used option that displays the equation names in the coefficient table. `ml display` uses the numbers stored in `e(k_eq)` and `e(k_aux)` to determine how to display the coefficient table. `e(k_eq)` identifies the number of equations, and `e(k_aux)` identifies how many of these are for ancillary parameters. The `first` option is implied when `showeqns` is not specified and all but the first equation are for ancillary parameters.

`plus` displays the coefficient table, but rather than ending the table in a line of dashes, ends it in dashes–plus-sign–dashes. This is so that programmers can write additional display code to add more results to the table and make it appear as if the combined result is one table. Programmers typically specify `plus` with the `first` or `neq()` options. This option implies `nofootnote`.

`nocnsreport` suppresses the display of constraints above the coefficient table. This option is ignored if constraints were not used to fit the model.

`noomitted` specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as "(omitted)".

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`noemptycells` specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as "(empty)".

`baselevels` and `allbaselevels` control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.

`baselevels` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.

`allbaselevels` specifies that all base levels of factor variables and interactions be reported.

`cformat(%`*fmt*`)` specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

`pformat(%`*fmt*`)` specifies how to format p-values in the coefficient table.

`sformat(%`*fmt*`)` specifies how to format test statistics in the coefficient table.

`nolstretch` specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the coefficient table up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

`coeflegend` specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

eform_option: `eform(`*string*`)`, `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` display the coefficient table in exponentiated form: for each coefficient, $\exp(b)$ rather than b is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or shorter in length—for example, `eform("Odds ratio")`. The options `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` provide a default *string* equivalent to "`exp(b)`", "`Haz. Ratio`", "`SHR`", "`IRR`", "`Odds Ratio`", and "`RRR`", respectively. These options may not be combined.

`ml display` looks at `e(k_eform)` to determine how many equations are affected by an *eform_option*; by default, only the first equation is affected. Type `ereturn list, all` to view `e(k_eform)`; see [P] **ereturn**.

Options for use with mleval

`eq(#)` specifies the equation number, i, for which $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$ is to be evaluated. `eq(1)` is assumed if `eq()` is not specified.

`scalar` asserts that the ith equation is known to evaluate to a constant, meaning that the equation was specified as `()`, (*name*`:`), or `/`*name* on the `ml model` statement. If you specify this option, the new variable created is created as a scalar. If the ith equation does not evaluate to a scalar, an error message is issued.

Option for use with mlsum

`noweight` specifies that weights (`$ML_w`) be ignored when summing the likelihood function.

Option for use with mlvecsum

`eq(#)` specifies the equation for which a gradient vector $\partial \ln L/\partial \mathbf{b}_i$ is to be constructed. The default is `eq(1)`.

Option for use with mlmatsum

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1,1)`, which means $\partial^2 \ln L/\partial \mathbf{b}_1 \partial \mathbf{b}_1'$. Specifying `eq(`$i$`,`$j$`)` results in $\partial^2 \ln L/\partial \mathbf{b}_i \partial \mathbf{b}_j'$.

Options for use with mlmatbysum

`by(`*varname*`)` is required and specifies the group variable.

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1,1)`, which means $\partial^2 \ln L/\partial \mathbf{b}_1 \partial \mathbf{b}_1'$. Specifying `eq(`$i$`,`$j$`)` results in $\partial^2 \ln L/\partial \mathbf{b}_i \partial \mathbf{b}_j'$.

Options for use with ml score

`equation(`*eqname*`)` identifies from which equation the observation scores are to come. This option may be used only when generating one variable.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample.

Remarks

For a thorough discussion of `ml`, see the fourth edition of *Maximum Likelihood Estimation with Stata* (Gould, Pitblado, and Poi 2010). The book provides a tutorial introduction to `ml`, notes on advanced programming issues, and a discourse on maximum likelihood estimation from both theoretical and practical standpoints. See *Survey options and ml* at the end of *Remarks* for examples of the new `svy` options. For more information about survey estimation, see [SVY] **survey**, [SVY] **svy estimation**, and [SVY] **variance estimation**.

`ml` requires that you write a program that evaluates the log-likelihood function and, possibly, its first and second derivatives. The style of the program you write depends upon the method you choose. Methods lf, lf0, d0, and gf0 require that your program evaluate the log likelihood only. Methods d1 and lf1 require that your program evaluate the log likelihood and its first derivatives. Methods d2 and lf2 requires that your program evaluate the log likelihood and its first and second derivatives. Methods lf, lf0, d0, and gf0 differ from each other in that, with methods lf and lf0, your program is required to produce observation-by-observation log-likelihood values $\ln \ell_j$ and it is assumed that $\ln L = \sum_j \ln \ell_j$; with method d0, your program is required to produce only the overall value $\ln L$; and with method gf0, your program is required to produce the summable pieces of the log likelihood, such as those in panel-data models.

Once you have written the program—called an evaluator—you define a model to be fit using `ml model` and obtain estimates using `ml maximize`. You might type

```
. ml model ...
. ml maximize
```

but we recommend that you type

```
. ml model ...
. ml check
. ml search
. ml maximize
```

`ml check` verifies your evaluator has no obvious errors, and `ml search` finds better initial values.

You fill in the `ml model` statement with 1) the method you are using, 2) the name of your program, and 3) the "equations". You write your evaluator in terms of θ_1, θ_2, ..., each of which has a linear equation associated with it. That linear equation might be as simple as $\theta_i = b_0$, it might be $\theta_i = b_1\texttt{mpg} + b_2\texttt{weight} + b_3$, or it might omit the intercept b_3. The equations are specified in parentheses on the `ml model` line.

Suppose that you are using method lf and the name of your evaluator program is `myprog`. The statement

```
. ml model lf myprog (mpg weight)
```

would specify one equation with $\theta_i = b_1\texttt{mpg} + b_2\texttt{weight} + b_3$. If you wanted to omit b_3, you would type

```
. ml model lf myprog (mpg weight, nocons)
```

and if all you wanted was $\theta_i = b_0$, you would type

```
. ml model lf myprog ()
```

With multiple equations, you list the equations one after the other; so, if you typed

```
. ml model lf myprog (mpg weight) ()
```

you would be specifying $\theta_1 = b_1\texttt{mpg} + b_2\texttt{weight} + b_3$ and $\theta_2 = b_4$. You would write your likelihood in terms of θ_1 and θ_2. If the model was linear regression, θ_1 might be the $\mathbf{xb}$ part and θ_2 the variance of the residuals.

When you specify the equations, you also specify any dependent variables. If you typed

```
. ml model lf myprog (price = mpg weight) ()
```

`price` would be the one and only dependent variable, and that would be passed to your program in `$ML_y1`. If your model had two dependent variables, you could type

```
. ml model lf myprog (price displ = mpg weight) ()
```

Then `$ML_y1` would be `price` and `$ML_y2` would be `displ`. You can specify however many dependent variables are necessary and specify them on any equation. It does not matter on which equation you specify them; the first one specified is placed in `$ML_y1`, the second in `$ML_y2`, and so on.

▷ Example 1: Method lf

Using method lf, we want to produce observation-by-observation values of the log likelihood. The probit log-likelihood function is

$$\ln \ell_j = \begin{cases} \ln \Phi(\theta_{1j}) & \text{if } y_j = 1 \\ \ln \Phi(-\theta_{1j}) & \text{if } y_j = 0 \end{cases}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

The following is the method-lf evaluator for this likelihood function:

```
program myprobit
        version 12
        args lnf theta1
        quietly replace `lnf' = ln(normal(`theta1')) if $ML_y1==1
        quietly replace `lnf' = ln(normal(-`theta1')) if $ML_y1==0
end
```

If we wanted to fit a model of `foreign` on `mpg` and `weight`, we would type

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. ml model lf myprobit (foreign = mpg weight)
. ml maximize
```

The '`foreign =`' part specifies that y is `foreign`. The '`mpg weight`' part specifies that $\theta_{1j} = b_1\texttt{mpg}_j + b_2\texttt{weight}_j + b_3$. The result of running this is

```
. ml model lf myprobit (foreign = mpg weight)
. ml maximize
initial:       log likelihood = -51.292891
alternative:   log likelihood = -45.055272

◁

▷ Example 2: Method lf for two-equation, two-dependent-variable model

A two-equation, two-dependent-variable model is a little different. Rather than receiving one θ, our program will receive two. Rather than there being one dependent variable in `$ML_y1`, there will be dependent variables in `$ML_y1` and `$ML_y2`. For instance, the Weibull regression log-likelihood function is

$$\ln \ell_j = -(t_j e^{-\theta_{1j}})^{\exp(\theta_{2j})} + d_j\{\theta_{2j} - \theta_{1j} + (e^{\theta_{2j}} - 1)(\ln t_j - \theta_{1j})\}$$
$$\theta_{1j} = \mathbf{x}_j\mathbf{b}_1$$
$$\theta_{2j} = s$$

where t_j is the time of failure or censoring and $d_j = 1$ if failure and 0 if censored. We can make the log likelihood a little easier to program by introducing some extra variables:

$$p_j = \exp(\theta_{2j})$$
$$M_j = \{t_j \exp(-\theta_{1j})\}^{p_j}$$
$$R_j = \ln t_j - \theta_{1j}$$
$$\ln \ell_j = -M_j + d_j\{\theta_{2j} - \theta_{1j} + (p_j - 1)R_j\}$$

The method-lf evaluator for this is

```
program myweib
        version 12
        args lnf theta1 theta2
        tempvar p M R
        quietly gen double `p' = exp(`theta2')
        quietly gen double `M' = ($ML_y1*exp(-`theta1'))^`p'
        quietly gen double `R' = ln($ML_y1)-`theta1'
        quietly replace `lnf' = -`M' + $ML_y2*(`theta2'-`theta1' + (`p'-1)*`R')
end
```

We can fit a model by typing

```
. ml model lf myweib (studytime died = i.drug age) ()
. ml maximize
```

Note that we specified `()` for the second equation. The second equation corresponds to the Weibull shape parameter s, and the linear combination we want for s contains just an intercept. Alternatively, we could type

```
. ml model lf myweib (studytime died = i.drug age) /s
```

Typing `/s` means the same thing as typing `(s:)`, and both really mean the same thing as `()`. The `s`, either after a slash or in parentheses before a colon, labels the equation. It makes the output look prettier, and that is all:

```
. use http://www.stata-press.com/data/r12/cancer, clear
(Patient Survival in Drug Trial)
. ml model lf myweib (studytime died = i.drug age) /s
. ml maximize
initial:       log likelihood =       -744
alternative:   log likelihood = -356.14276
rescale:       log likelihood = -200.80201
rescale eq:    log likelihood = -136.69232
Iteration 0:   log likelihood = -136.69232  (not concave)
Iteration 1:   log likelihood = -124.11726
Iteration 2:   log likelihood = -113.89828
Iteration 3:   log likelihood = -110.30451

◁

▷ Example 3: Method d0

Method-d0 evaluators receive $\mathbf{b} = (\mathbf{b}_1, \mathbf{b_2}, \ldots, \mathbf{b}_E)$, the coefficient vector, rather than the already evaluated $\theta_1, \theta_2, \ldots, \theta_E$, and they are required to evaluate the overall log-likelihood $\ln L$ rather than $\ln \ell_j$, $j = 1, \ldots, N$.

Use `mleval` to produce the thetas from the coefficient vector.

Use `mlsum` to sum the components that enter into $\ln L$.

In the case of Weibull, $\ln L = \sum \ln \ell_j$, and our method-d0 evaluator is

```
program weib0
        version 12
        args todo b lnf
        tempvar theta1 theta2
        mleval `theta1' = `b', eq(1)
        mleval `theta2' = `b', eq(2)
        local t "$ML_y1"           // this is just for readability
        local d "$ML_y2"
        tempvar p M R
        quietly gen double `p' = exp(`theta2')
        quietly gen double `M' = (`t'*exp(-`theta1'))^`p'
        quietly gen double `R' = ln(`t')-`theta1'
        mlsum `lnf' = -`M' + `d'*(`theta2'-`theta1' + (`p'-1)*`R')
end
```

To fit our model using this evaluator, we would type

```
. ml model d0 weib0 (studytime died = i.drug age) /s
. ml maximize
```

◁

❑ Technical note

Method d0 does not require $\ln L = \sum_j \ln \ell_j$, $j = 1, \ldots, N$, as method lf does. Your likelihood function might have independent components only for groups of observations. Panel-data estimators have a log-likelihood value $\ln L = \sum_i \ln L_i$, where i indexes the panels, each of which contains multiple observations. Conditional logistic regression has $\ln L = \sum_k \ln L_k$, where k indexes the risk pools. Cox regression has $\ln L = \sum_{(t)} \ln L_{(t)}$, where (t) denotes the ordered failure times.

To evaluate such likelihood functions, first calculate the within-group log-likelihood contributions. This usually involves `generate` and `replace` statements prefixed with `by`, as in

```
tempvar sumd
by group: gen double `sumd' = sum($ML_y1)
```

Structure your code so that the log-likelihood contributions are recorded in the last observation of each group. Say that a variable is named `'cont'`. To sum the contributions, code

```
tempvar last
quietly by group: gen byte `last' = (_n==_N)
mlsum `lnf' = `cont' if `last'
```

You must inform `mlsum` which observations contain log-likelihood values to be summed. First, you do not want to include intermediate results in the sum. Second, `mlsum` does not skip missing values. Rather, if `mlsum` sees a missing value among the contributions, it sets the overall result, `'lnf'`, to missing. That is how `ml maximize` is informed that the likelihood function could not be evaluated at the particular value of `b`. `ml maximize` will then take action to escape from what it thinks is an infeasible area of the likelihood function.

When the likelihood function violates the linear-form restriction $\ln L = \sum_j \ln \ell_j$, $j = 1, \ldots, N$, with $\ln \ell_j$ being a function solely of values within the jth observation, use method d0. In the following examples, we will demonstrate methods d1 and d2 with likelihood functions that meet this linear-form restriction. The d1 and d2 methods themselves do not require the linear-form restriction, but the utility routines `mlvecsum` and `mlmatsum` do. Using method d1 or d2 when the restriction is violated is difficult; however, `mlmatbysum` may be of some help for method-d2 evaluators. ❑

▷ Example 4: Method d1

Method-d1 evaluators are required to produce the gradient vector $\mathbf{g} = \partial \ln L/\partial \mathbf{b}$, as well as the overall log-likelihood value. Using `mlvecsum`, we can obtain $\partial \ln L/\partial \mathbf{b}$ from $\partial \ln L/\partial \theta_i$, $i = 1, \ldots, E$. The derivatives of the Weibull log-likelihood function are

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}} = p_j(M_j - d_j)$$
$$\frac{\partial \ln \ell_j}{\partial \theta_{2j}} = d_j - R_j p_j(M_j - d_j)$$

The method-d1 evaluator for this is

```
program weib1
        version 12
        args todo b lnf g                                       // g is new

        tempvar t1 t2
        mleval `t1' = `b', eq(1)
        mleval `t2' = `b', eq(2)

        local t "$ML_y1"
        local d "$ML_y2"

        tempvar p M R
        quietly gen double `p' = exp(`t2')
        quietly gen double `M' = (`t'*exp(-`t1'))^`p'
        quietly gen double `R' = ln(`t')-`t1'

        mlsum `lnf' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
        if (`todo'==0 | `lnf'>=.) exit                          /* <-- new */

        tempname d1 d2                                          /* <-- new */
        mlvecsum `lnf' `d1' = `p'*(`M'-`d'), eq(1)              /* <-- new */
        mlvecsum `lnf' `d2' = `d' - `R'*`p'*(`M'-`d'), eq(2)    /* <-- new */
        matrix `g' = (`d1',`d2')                                /* <-- new */
end
```

We obtained this code by starting with our method-d0 evaluator and then adding the extra lines that method d1 requires. To fit our model using this evaluator, we could type

```
. ml model d1 weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we recommend substituting method d1debug for method d1 and typing

```
. ml model d1debug weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d1debug will compare the derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d1debug to method d1.

◁

▷ Example 5: Method d2

Method-d2 evaluators are required to produce $\mathbf{H} = \partial^2 \ln L/\partial \mathbf{b} \partial \mathbf{b}'$, the Hessian matrix, as well as the gradient and log-likelihood value. `mlmatsum` will help calculate $\partial^2 \ln L/\partial \mathbf{b} \partial \mathbf{b}'$ from the second derivatives with respect to θ. For the Weibull model, these second derivatives are

$$\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} = -p_j^2 M_j$$

$$\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} = p_j(M_j - d_j + R_j p_j M_j)$$

$$\frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} = -p_j R_j(R_j p_j M_j + M_j - d_j)$$

The method-d2 evaluator is

```
program weib2
        version 12
        args todo b lnf g H                         // H added
        tempvar t1 t2
        mleval `t1' = `b', eq(1)
        mleval `t2' = `b', eq(2)
        local t "$ML_y1"
        local d "$ML_y2"
        tempvar p M R
        quietly gen double `p' = exp(`t2')
        quietly gen double `M' = (`t'*exp(-`t1'))^`p'
        quietly gen double `R' = ln(`t')-`t1'
        mlsum `lnf' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
        if (`todo'==0 | `lnf'>=.) exit
        tempname d1 d2
        mlvecsum `lnf' `d1' = `p'*(`M'-`d'), eq(1)
        mlvecsum `lnf' `d2' = `d' - `R'*`p'*(`M'-`d'), eq(2)
        matrix `g' = (`d1',`d2')
        if (`todo'==1 | `lnf'>=.) exit              // new from here down
        tempname d11 d12 d22
        mlmatsum `lnf' `d11' = -`p'^2 * `M', eq(1)
        mlmatsum `lnf' `d12' = `p'*(`M'-`d' + `R'*`p'*`M'), eq(1,2)
        mlmatsum `lnf' `d22' = -`p'*`R'*(`R'*`p'*`M' + `M' - `d') , eq(2)
        matrix `H' = (`d11',`d12' \ `d12'',`d22')
end
```

We started with our previous method-d1 evaluator and added the lines that method d2 requires. We could now fit a model by typing

```
. ml model d2 weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we would recommend substituting method d2debug for method d2 and typing

```
. ml model d2debug weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d2debug will compare the first and second derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d2debug to method d2. ◁

As we stated earlier, to produce the robust variance estimator with method lf, there is nothing to do except specify `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweight`. For methods d0, d1, and d2, these options do not work. If your likelihood function meets the linear-form restrictions, you can use methods lf0, lf1, and lf2, then these options will work. The equation scores are defined as

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}}, \quad \frac{\partial \ln \ell_j}{\partial \theta_{2j}}, \quad \ldots$$

Your evaluator will be passed variables, one for each equation, which you fill in with the equation scores. For *both* method lf1 and lf2, these variables are passed in the fourth and subsequent positions of the argument list. That is, you must process the arguments as

```
args todo b lnf g1 g2 ... H
```

Note that for method lf1, the `H` argument is not used and can be ignored.

▷ Example 6: Robust variance estimates

If you have used `mlvecsum` in your evaluator of method d1 or d2, it is easy to turn it into evaluator of method lf1 or lf2 that allows the computation of the robust variance estimator. The expression that you specified on the right-hand side of `mlvecsum` is the equation score.

Here we turn the program that we gave earlier in the method-d1 example into a method-lf1 evaluator that allows `vce(robust)`, `vce(cluster` *clustvar*`)`, or `pweight`.

```
program weib1
        version 12
        args todo b lnfj g1 g2          // g1 and g2 are new
        tempvar t1 t2
        mleval `t1' = `b', eq(1)
        mleval `t2' = `b', eq(2)
        local t "$ML_y1"
        local d "$ML_y2"
        tempvar p M R
        quietly gen double `p' = exp(`t2')
        quietly gen double `M' = (`t'*exp(-`t1'))^`p'
        quietly gen double `R' = ln(`t')-`t1'
        quietly replace `lnfj' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
        if (`todo'==0) exit
        quietly replace `g1' = `p'*(`M'-`d')              /* <-- new     */
        quietly replace `g2' = `d' - `R'*`p'*(`M'-`d')    /* <-- new     */
end
```

To fit our model and get the robust variance estimates, we type

```
. ml model lf1 weib1 (studytime died = drug2 drug3 age) /s, vce(robust)
. ml maximize
```

◁

Survey options and ml

`ml` can handle stratification, poststratification, multiple stages of clustering, and finite population corrections. Specifying the `svy` option implies that the data come from a survey design and also implies that the survey linearized variance estimator is to be used; see [SVY] **variance estimation**.

▷ Example 7

Suppose that we are interested in a probit analysis of data from a survey in which `q1` is the answer to a yes/no question and `x1`, `x2`, `x3` are demographic responses. The following is a lf2 evaluator for the probit model that meets the requirements for `vce(robust)` (linear form and computes the scores).

```
program mylf2probit
        version 12
        args todo b lnfj g1 H
        tempvar z Fz lnf
        mleval `z' = `b'
        quietly gen double `Fz'   = normal( `z')  if $ML_y1 == 1
        quietly replace    `Fz'   = normal(-`z')  if $ML_y1 == 0
        quietly replace    `lnfj' = log(`Fz')
        if (`todo'==0) exit
        quietly replace `g1' =  normalden(`z')/`Fz'  if $ML_y1 == 1
        quietly replace `g1' = -normalden(`z')/`Fz'  if $ML_y1 == 0
        if (`todo'==1) exit
        mlmatsum `lnf' `H' = -`g1'*(`g1'+`z'), eq(1,1)
end
```

To fit a model, we `svyset` the data, then use `svy` with `ml`.

```
. svyset psuid [pw=w], strata(strid)
. ml model lf2 myd2probit (q1 = x1 x2 x3), svy
. ml maximize
```

We could also use the `subpop()` option to make inferences about the subpopulation identified by the variable `sub`:

```
. svyset psuid [pw=w], strata(strid)
. ml model lf2 myd2probit (q1 = x1 x2 x3), svy subpop(sub)
. ml maximize
```

◁

Saved results

For results saved by `ml` without the `svy` option, see [R] **maximize**.

For results saved by `ml` with the `svy` option, see [SVY] **svy**.

Methods and formulas

`ml` is implemented using `moptimize`; see [M-5] **moptimize( )**.

Title

mlogit — Multinomial (polytomous) logistic regression

Syntax

`mlogit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`noconstant`	suppress constant term
`baseoutcome(#)`	value of *depvar* that will be the base outcome
`constraints(`*clist*`)`	apply specified linear constraints; *clist* has the form #[-#] [, #[-#] ...]
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`rrr`	report relative-risk ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

indepvars may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Categorical outcomes > Multinomial logistic regression

Description

`mlogit` fits maximum-likelihood multinomial logit models, also known as polytomous logistic regression. You can define constraints to perform constrained estimation. Some people refer to conditional logistic regression as multinomial logit. If you are one of them, see [R] **clogit**.

See [R] **logistic** for a list of related estimation commands.

Options

Model

`noconstant`; see [R] **estimation options**.

`baseoutcome(#)` specifies the value of *depvar* to be treated as the base outcome. The default is to choose the most frequent outcome.

`constraints(`*clist*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

Reporting

`level(#)`; see [R] **estimation options**.

`rrr` reports the estimated coefficients transformed to relative-risk ratios, that is, e^b rather than b; see *Description of the model* below for an explanation of this concept. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `rrr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The following option is available with `mlogit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Description of the model
Fitting unconstrained models
Fitting constrained models

`mlogit` fits maximum likelihood models with discrete dependent (left-hand-side) variables when the dependent variable takes on more than two outcomes and the outcomes have no natural ordering. If the dependent variable takes on only two outcomes, estimates are identical to those produced by `logistic` or `logit`; see [R] **logistic** or [R] **logit**. If the outcomes are ordered, see [R] **ologit**.

Description of the model

For an introduction to multinomial logit models, see Greene (2012, 763–766), Hosmer and Lemeshow (2000, 260–287), Long (1997, chap. 6), Long and Freese (2006, chap. 6 and 7), and Treiman (2009, 336–341). For a description emphasizing the difference in assumptions and data requirements for conditional and multinomial logit, see Davidson and MacKinnon (1993).

Consider the outcomes 1, 2, 3, ..., m recorded in y, and the explanatory variables X. Assume that there are $m = 3$ outcomes: "buy an American car", "buy a Japanese car", and "buy a European car". The values of y are then said to be "unordered". Even though the outcomes are coded 1, 2, and 3, the numerical values are arbitrary because $1 < 2 < 3$ does not imply that outcome 1 (buy American) is less than outcome 2 (buy Japanese) is less than outcome 3 (buy European). This unordered categorical property of y distinguishes the use of `mlogit` from `regress` (which is appropriate for a continuous dependent variable), from `ologit` (which is appropriate for ordered categorical data), and from `logit` (which is appropriate for two outcomes, which can be thought of as ordered).

In the multinomial logit model, you estimate a set of coefficients, $\beta^{(1)}$, $\beta^{(2)}$, and $\beta^{(3)}$, corresponding to each outcome:

$$\Pr(y=1) = \frac{e^{X\beta^{(1)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y=2) = \frac{e^{X\beta^{(2)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y=3) = \frac{e^{X\beta^{(3)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The model, however, is unidentified in the sense that there is more than one solution to $\beta^{(1)}$, $\beta^{(2)}$, and $\beta^{(3)}$ that leads to the same probabilities for $y = 1$, $y = 2$, and $y = 3$. To identify the model, you arbitrarily set one of $\beta^{(1)}$, $\beta^{(2)}$, or $\beta^{(3)}$ to 0—it does not matter which. That is, if you arbitrarily set $\beta^{(1)} = 0$, the remaining coefficients $\beta^{(2)}$ and $\beta^{(3)}$ will measure the change relative to the $y = 1$ group. If you instead set $\beta^{(2)} = 0$, the remaining coefficients $\beta^{(1)}$ and $\beta^{(3)}$ will measure the change relative to the $y = 2$ group. The coefficients will differ because they have different interpretations, but the predicted probabilities for $y = 1$, 2, and 3 will still be the same. Thus either parameterization will be a solution to the same underlying model.

Setting $\beta^{(1)} = 0$, the equations become

$$\Pr(y=1) = \frac{1}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y=2) = \frac{e^{X\beta^{(2)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y=3) = \frac{e^{X\beta^{(3)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The relative probability of $y = 2$ to the base outcome is

$$\frac{\Pr(y=2)}{\Pr(y=1)} = e^{X\beta^{(2)}}$$

Let's call this ratio the relative risk, and let's further assume that X and $\beta_k^{(2)}$ are vectors equal to $(x_1, x_2, \ldots, x_k)$ and $(\beta_1^{(2)}, \beta_2^{(2)}, \ldots, \beta_k^{(2)})'$, respectively. The ratio of the relative risk for a one-unit change in x_i is then

$$\frac{e^{\beta_1^{(2)}x_1+\cdots+\beta_i^{(2)}(x_i+1)+\cdots+\beta_k^{(2)}x_k}}{e^{\beta_1^{(2)}x_1+\cdots+\beta_i^{(2)}x_i+\cdots+\beta_k^{(2)}x_k}} = e^{\beta_i^{(2)}}$$

Thus the exponentiated value of a coefficient is the relative-risk ratio for a one-unit change in the corresponding variable (risk is measured as the risk of the outcome relative to the base outcome).

Fitting unconstrained models

▷ Example 1

We have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). The insurance is categorized as either an indemnity plan (that is, regular fee-for-service insurance, which may have a deductible or coinsurance rate) or a prepaid plan (a fixed up-front payment allowing subsequent unlimited use as provided, for instance, by an HMO). The third possibility is that the subject has no insurance whatsoever. We wish to explore the demographic factors associated with each subject's insurance choice. One of the demographic factors in our data is the race of the participant, coded as white or nonwhite:

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. tabulate insure nonwhite, chi2 col
```

Key
frequency *column percentage*

insure	nonwhite 0	1	Total
Indemnity	251 50.71	43 35.54	294 47.73
Prepaid	208 42.02	69 57.02	277 44.97
Uninsure	36 7.27	9 7.44	45 7.31
Total	495 100.00	121 100.00	616 100.00

Pearson chi2(2) = 9.5599 Pr = 0.008

Although insure appears to take on the values Indemnity, Prepaid, and Uninsure, it actually takes on the values 1, 2, and 3. The words appear because we have associated a value label with the numeric variable insure; see [U] **12.6.3 Value labels**.

When we fit a multinomial logit model, we can tell mlogit which outcome to use as the base outcome, or we can let mlogit choose. To fit a model of insure on nonwhite, letting mlogit choose the base outcome, we type

```
. mlogit insure nonwhite
Iteration 0:   log likelihood = -556.59502
Iteration 1:   log likelihood = -551.78935
Iteration 2:   log likelihood = -551.78348
Iteration 3:   log likelihood = -551.78348
Multinomial logistic regression                 Number of obs   =        616
                                                LR chi2(2)      =       9.62
                                                Prob > chi2     =     0.0081
Log likelihood = -551.78348                     Pseudo R2       =     0.0086
```

insure	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
Indemnity	(base outcome)					
Prepaid						
nonwhite	.6608212	.2157321	3.06	0.002	.2379942	1.083648
_cons	-.1879149	.0937644	-2.00	0.045	-.3716896	-.0041401
Uninsure						
nonwhite	.3779586	.407589	0.93	0.354	-.4209011	1.176818
_cons	-1.941934	.1782185	-10.90	0.000	-2.291236	-1.592632

mlogit chose the indemnity outcome as the base outcome and presented coefficients for the outcomes prepaid and uninsured. According to the model, the probability of prepaid for whites (nonwhite = 0) is

$$\Pr(\texttt{insure} = \texttt{Prepaid}) = \frac{e^{-.188}}{1 + e^{-.188} + e^{-1.942}} = 0.420$$

Similarly, for nonwhites, the probability of prepaid is

$$\Pr(\texttt{insure} = \texttt{Prepaid}) = \frac{e^{-.188+.661}}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.570$$

These results agree with the column percentages presented by tabulate because the mlogit model is fully saturated. That is, there are enough terms in the model to fully explain the column percentage in each cell. The model chi-squared and the tabulate chi-squared are in almost perfect agreement; both test that the column percentages of insure are the same for both values of nonwhite.

◁

▷ Example 2

By specifying the baseoutcome() option, we can control which outcome of the dependent variable is treated as the base. Left to its own, mlogit chose to make outcome 1, indemnity, the base outcome. To make outcome 2, prepaid, the base, we would type

```
. mlogit insure nonwhite, base(2)
Iteration 0:   log likelihood = -556.59502
Iteration 1:   log likelihood = -551.78935
Iteration 2:   log likelihood = -551.78348
Iteration 3:   log likelihood = -551.78348
Multinomial logistic regression                 Number of obs   =        616
                                                LR chi2(2)      =       9.62
                                                Prob > chi2     =     0.0081
Log likelihood = -551.78348                     Pseudo R2       =     0.0086
```

insure	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
Indemnity						
nonwhite	-.6608212	.2157321	-3.06	0.002	-1.083648	-.2379942
_cons	.1879149	.0937644	2.00	0.045	.0041401	.3716896
Prepaid	(base outcome)					
Uninsure						
nonwhite	-.2828627	.3977302	-0.71	0.477	-1.0624	.4966742
_cons	-1.754019	.1805145	-9.72	0.000	-2.107821	-1.400217

The `baseoutcome()` option requires that we specify the numeric value of the outcome, so we could not type `base(Prepaid)`.

Although the coefficients now appear to be different, the summary statistics reported at the top are identical. With this parameterization, the probability of prepaid insurance for whites is

$$\Pr(\texttt{insure} = \texttt{Prepaid}) = \frac{1}{1 + e^{.188} + e^{-1.754}} = 0.420$$

This is the same answer we obtained previously. ◁

▷ Example 3

By specifying `rrr`, which we can do at estimation time or when we redisplay results, we see the model in terms of relative-risk ratios:

```
. mlogit, rrr
Multinomial logistic regression                 Number of obs   =        616
                                                LR chi2(2)      =       9.62
                                                Prob > chi2     =     0.0081
Log likelihood = -551.78348                     Pseudo R2       =     0.0086
```

insure	RRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
Indemnity						
nonwhite	.516427	.1114099	-3.06	0.002	.3383588	.7882073
_cons	1.206731	.1131483	2.00	0.045	1.004149	1.450183
Prepaid	(base outcome)					
Uninsure						
nonwhite	.7536233	.2997387	-0.71	0.477	.3456255	1.643247
_cons	.1730769	.0312429	-9.72	0.000	.1215024	.2465434

Looked at this way, the relative risk of choosing an indemnity over a prepaid plan is 0.516 for nonwhites relative to whites.

To illustrate, from the output and discussions of examples 1 and 2 we find that

$$\Pr(\texttt{insure} = \texttt{Indemnity} \mid \text{white}) = \frac{1}{1 + e^{-.188} + e^{-1.942}} = 0.507$$

and thus the relative risk of choosing indemnity over prepaid (for whites) is

$$\frac{\Pr(\texttt{insure} = \texttt{Indemnity} \mid \text{white})}{\Pr(\texttt{insure} = \texttt{Prepaid} \mid \text{white})} = \frac{0.507}{0.420} = 1.207$$

For nonwhites,

$$\Pr(\texttt{insure} = \texttt{Indemnity} \mid \text{not white}) = \frac{1}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.355$$

and thus the relative risk of choosing indemnity over prepaid (for nonwhites) is

$$\frac{\Pr(\texttt{insure} = \texttt{Indemnity} \mid \text{not white})}{\Pr(\texttt{insure} = \texttt{Prepaid} \mid \text{not white})} = \frac{0.355}{0.570} = 0.623$$

The ratio of these two relative risks, hence the name "relative-risk ratio", is $0.623/1.207 = 0.516$, as given in the output under the heading "RRR".

◁

❑ Technical note

In models where only two categories are considered, the `mlogit` model reduces to standard `logit`. Consequently the exponentiated regression coefficients, labeled as `RRR` within `mlogit`, are equal to the odds ratios as given when the `or` option is specified under `logit`; see [R] **logit**.

As such, always referring to `mlogit`'s exponentiated coefficients as odds ratios may be tempting. However, the discussion in example 3 demonstrates that doing so would be incorrect. In general `mlogit` models, the exponentiated coefficients are ratios of relative risks, not ratios of odds.

❑

▷ Example 4

One of the advantages of `mlogit` over `tabulate` is that we can include continuous variables and multiple categorical variables in the model. In examining the data on insurance choice, we decide that we want to control for age, gender, and site of study (the study was conducted in three sites):

```
. mlogit insure age male nonwhite i.site
Iteration 0:   log likelihood = -555.85446
Iteration 1:   log likelihood = -534.67443
Iteration 2:   log likelihood = -534.36284
Iteration 3:   log likelihood = -534.36165
Iteration 4:   log likelihood = -534.36165
Multinomial logistic regression                 Number of obs   =        615
                                                LR chi2(10)     =      42.99
                                                Prob > chi2     =     0.0000
Log likelihood = -534.36165                     Pseudo R2       =     0.0387
```

insure	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
Indemnity	(base outcome)					
Prepaid						
age	-.011745	.0061946	-1.90	0.058	-.0238862	.0003962
male	.5616934	.2027465	2.77	0.006	.1643175	.9590693
nonwhite	.9747768	.2363213	4.12	0.000	.5115955	1.437958
site						
2	.1130359	.2101903	0.54	0.591	-.2989296	.5250013
3	-.5879879	.2279351	-2.58	0.010	-1.034733	-.1412433
_cons	.2697127	.3284422	0.82	0.412	-.3740222	.9134476
Uninsure						
age	-.0077961	.0114418	-0.68	0.496	-.0302217	.0146294
male	.4518496	.3674867	1.23	0.219	-.268411	1.17211
nonwhite	.2170589	.4256361	0.51	0.610	-.6171725	1.05129
site						
2	-1.211563	.4705127	-2.57	0.010	-2.133751	-.2893747
3	-.2078123	.3662926	-0.57	0.570	-.9257327	.510108
_cons	-1.286943	.5923219	-2.17	0.030	-2.447872	-.1260134

These results suggest that the inclination of nonwhites to choose prepaid care is even stronger than it was without controlling. We also see that subjects in site 2 are less likely to be uninsured.

◁

Fitting constrained models

`mlogit` can fit models with subsets of coefficients constrained to be zero, with subsets of coefficients constrained to be equal both within and across equations, and with subsets of coefficients arbitrarily constrained to equal linear combinations of other estimated coefficients.

Before fitting a constrained model, you define the constraints with the `constraint` command; see [R] **constraint**. Once the constraints are defined, you estimate using `mlogit`, specifying the `constraint()` option. Typing `constraint(4)` would use the constraint you previously saved as 4. Typing `constraint(1,4,6)` would use the previously stored constraints 1, 4, and 6. Typing `constraint(1-4,6)` would use the previously stored constraints 1, 2, 3, 4, and 6.

Sometimes you will not be able to specify the constraints without knowing the omitted outcome. In such cases, assume that the omitted outcome is whatever outcome is convenient for you, and include the `baseoutcome()` option when you specify the `mlogit` command.

▷ Example 5

We can use constraints to test hypotheses, among other things. In our insurance-choice model, let's test the hypothesis that there is no distinction between having indemnity insurance and being uninsured. Indemnity-style insurance was the omitted outcome, so we type

```
. test [Uninsure]
 ( 1)  [Uninsure]age = 0
 ( 2)  [Uninsure]male = 0
 ( 3)  [Uninsure]nonwhite = 0
 ( 4)  [Uninsure]1b.site = 0
 ( 5)  [Uninsure]2.site = 0
 ( 6)  [Uninsure]3.site = 0
       Constraint 4 dropped
           chi2(  5) =    9.31
         Prob > chi2 =    0.0973
```

If indemnity had not been the omitted outcome, we would have typed `test [Uninsure=Indemnity]`.

The results produced by `test` are an approximation based on the estimated covariance matrix of the coefficients. Because the probability of being uninsured is low, the log likelihood may be nonlinear for the uninsured. Conventional statistical wisdom is not to trust the asymptotic answer under these circumstances but to perform a likelihood-ratio test instead.

To use Stata's `lrtest` (likelihood-ratio test) command, we must fit both the unconstrained and constrained models. The unconstrained model is the one we have previously fit. Following the instruction in [R] **lrtest**, we first save the unconstrained model results:

```
. estimates store unconstrained
```

To fit the constrained model, we must refit our model with all the coefficients except the constant set to 0 in the `Uninsure` equation. We define the constraint and then refit:

```
. constraint 1 [Uninsure]
. mlogit insure age male nonwhite i.site, constraints(1)
Iteration 0:   log likelihood = -555.85446
Iteration 1:   log likelihood = -539.80523
Iteration 2:   log likelihood = -539.75644
Iteration 3:   log likelihood = -539.75643
Multinomial logistic regression                 Number of obs   =        615
                                                Wald chi2(5)    =      29.70
Log likelihood = -539.75643                     Prob > chi2     =     0.0000
 ( 1)  [Uninsure]o.age = 0
 ( 2)  [Uninsure]o.male = 0
 ( 3)  [Uninsure]o.nonwhite = 0
 ( 4)  [Uninsure]2o.site = 0
 ( 5)  [Uninsure]3o.site = 0
```

insure	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
Indemnity	(base outcome)					
Prepaid						
age	-.0107025	.0060039	-1.78	0.075	-.0224699	.0010649
male	.4963616	.1939683	2.56	0.010	.1161907	.8765324
nonwhite	.9421369	.2252094	4.18	0.000	.5007346	1.383539
site						
2	.2530912	.2029465	1.25	0.212	-.1446767	.6508591
3	-.5521773	.2187237	-2.52	0.012	-.9808678	-.1234869
_cons	.1792752	.3171372	0.57	0.572	-.4423023	.8008527
Uninsure						
age	0	(omitted)				
male	0	(omitted)				
nonwhite	0	(omitted)				
site						
2	0	(omitted)				
3	0	(omitted)				
_cons	-1.87351	.1601099	-11.70	0.000	-2.18732	-1.5597

We can now perform the likelihood-ratio test:

```
. lrtest unconstrained .
Likelihood-ratio test                           LR chi2(5)  =     10.79
(Assumption: . nested in unconstrained)         Prob > chi2 =    0.0557
```

The likelihood-ratio chi-squared is 10.79 with 5 degrees of freedom—just slightly greater than the magic $p = 0.05$ level—so we should not call this difference significant. ◁

❑ Technical note

In certain circumstances, you should fit a multinomial logit model with conditional logit; see [R] **clogit**. With substantial data manipulation, `clogit` can handle the same class of models with some interesting additions. For example, if we had available the price and deductible of the most competitive insurance plan of each type, `mlogit` could not use this information, but `clogit` could. ❑

Saved results

mlogit saves the following in e():

e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(eqnames)	names of equations
e(baselab)	value label corresponding to base outcome
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(out)	outcome values
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

mlogit is implemented as an ado-file.

The multinomial logit model is described in Greene (2012, 763–766).

Suppose that there are k categorical outcomes and—without loss of generality—let the base outcome be 1. The probability that the response for the jth observation is equal to the ith outcome is

$$p_{ij} = \Pr(y_j = i) = \begin{cases} \dfrac{1}{1 + \sum_{m=2}^{k} \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, \text{ if } & i = 1 \\ \dfrac{\exp(\mathbf{x}_j \boldsymbol{\beta}_i)}{1 + \sum_{m=2}^{k} \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, \text{ if } & i > 1 \end{cases}$$

where $\mathbf{x}_j$ is the row vector of observed values of the independent variables for the jth observation and $\boldsymbol{\beta}_m$ is the coefficient vector for outcome m. The log pseudolikelihood is

$$\ln L = \sum_j w_j \sum_{i=1}^{k} I_i(y_j) \ln p_{ik}$$

where w_j is an optional weight and

$$I_i(y_j) = \begin{cases} 1, \text{ if } y_j = i \\ 0, \text{ otherwise} \end{cases}$$

Newton–Raphson maximum likelihood is used; see [R] **maximize**.

For constrained equations, the set of constraints is orthogonalized, and a subset of maximizable parameters is selected. For example, a parameter that is constrained to zero is not a maximizable parameter. If two parameters are constrained to be equal to each other, only one is a maximizable parameter.

Let $\mathbf{r}$ be the vector of maximizable parameters. $\mathbf{r}$ is physically a subset of the solution parameters, $\mathbf{b}$. A matrix, $\mathbf{T}$, and a vector, $\mathbf{m}$, are defined as

$$\mathbf{b} = \mathbf{T}\mathbf{r} + \mathbf{m}$$

so that

$$\frac{\partial f}{\partial \mathbf{b}} = \frac{\partial f}{\partial \mathbf{r}}\mathbf{T}'$$

$$\frac{\partial^2 f}{\partial \mathbf{b}^2} = \mathbf{T}\frac{\partial^2 f}{\partial \mathbf{r}^2}\mathbf{T}'$$

$\mathbf{T}$ consists of a block form in which one part is a permutation of the identity matrix and the other part describes how to calculate the constrained parameters from the maximizable parameters.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mlogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

mlogit postestimation — Postestimation tools for mlogit

Description

The following postestimation commands are available after `mlogit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] {stub* | newvar | newvarlist} [if] [in] [, statistic outcome(outcome)]

predict [type] {stub* | newvarlist} [if] [in], scores
```

statistic	Description
Main	
`pr`	probability of a positive outcome; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction
`stddp`	standard error of the difference in two linear predictions

If you do not specify `outcome()`, `pr` (with one new variable specified), `xb`, and `stdp` assume `outcome(#1)`. You must specify `outcome()` with the `stddp` option.

You specify one or k new variables with `pr`, where k is the number of outcomes.

You specify one new variable with `xb`, `stdp`, and `stddp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of each of the categories of the dependent variable or the probability of the level specified in `outcome(`*outcome*`)`. If you specify the `outcome(`*outcome*`)` option, you need to specify only one new variable; otherwise, you must specify a new variable for each category of the dependent variable.

`xb` calculates the linear prediction. You must also specify the `outcome(`*outcome*`)` option.

`stdp` calculates the standard error of the linear prediction. You must also specify the `outcome(`*outcome*`)` option.

`stddp` calculates the standard error of the difference in two linear predictions. You must specify the `outcome(`*outcome*`)` option, and here you specify the two particular outcomes of interest inside the parentheses, for example, `predict sed, stddp outcome(1,3)`.

`outcome(`*outcome*`)` specifies the outcome for which the statistic is to be calculated. `equation()` is a synonym for `outcome()`: it does not matter which you use. `outcome()` or `equation()` can be specified using

`#1`, `#2`, ..., where `#1` means the first category of the dependent variable, `#2` means the second category, etc.;

the values of the dependent variable; or

the value labels of the dependent variable if they exist.

`scores` calculates equation-level score variables. The number of score variables created will be one less than the number of outcomes in the model. If the number of outcomes in the model were k, then

the first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta}_1)$;

the second new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta}_2)$;

...

the $(k-1)$th new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta}_{k-1})$.

Remarks

Remarks are presented under the following headings:

Obtaining predicted values
Calculating marginal effects
Testing hypotheses about coefficients

Obtaining predicted values

▷ Example 1

After estimation, we can use `predict` to obtain predicted probabilities, index values, and standard errors of the index, or differences in the index. For instance, in example 4 of [R] **mlogit**, we fit a model of insurance choice on various characteristics. We can obtain the predicted probabilities for outcome 1 by typing

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. mlogit insure age i.male i.nonwhite i.site
  (output omitted)
. predict p1 if e(sample), outcome(1)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p1
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
          p1 |        615    .4764228    .1032279    .1698142     .71939
```

We added the `i.` prefix to the `male`, `nonwhite`, and `site` variables to explicitly identify them as factor variables. That makes no difference in the estimated results, but we will take advantage of it in later examples. We also included `if e(sample)` to restrict the calculation to the estimation sample. In example 4 of [R] **mlogit**, the multinomial logit model was fit on 615 observations, so there must be missing values in our dataset.

Although we typed `outcome(1)`, specifying `1` for the indemnity outcome, we could have typed `outcome(Indemnity)`. For instance, to obtain the probabilities for prepaid, we could type

```
. predict p2 if e(sample), outcome(prepaid)
(option pr assumed; predicted probability)
outcome prepaid not found
r(303);
. predict p2 if e(sample), outcome(Prepaid)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p2
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
          p2 |        615    .4504065    .1125962    .1964103    .7885724
```

We must specify the label exactly as it appears in the underlying value label (or how it appears in the `mlogit` output), including capitalization.

Here we have used `predict` to obtain probabilities for the same sample on which we estimated. That is not necessary. We could use another dataset that had the independent variables defined (in our example, `age`, `male`, `nonwhite`, and `site`) and use `predict` to obtain predicted probabilities; here, we would not specify `if e(sample)`.

◁

▷ Example 2

`predict` can also be used to obtain the index values—the $\sum x_i\widehat{\beta}_i^{(k)}$—as well as the probabilities:

```
. predict idx1, outcome(Indemnity) xb
(1 missing value generated)

. summarize idx1
```

Variable	Obs	Mean	Std. Dev.	Min	Max
idx1	643	0	0	0	0

The indemnity outcome was our base outcome—the outcome for which all the coefficients were set to 0—so the index is always 0. For the prepaid and uninsured outcomes, we type

```
. predict idx2, outcome(Prepaid) xb
(1 missing value generated)

. predict idx3, outcome(Uninsure) xb
(1 missing value generated)

. summarize idx2 idx3
```

Variable	Obs	Mean	Std. Dev.	Min	Max
idx2	643	-.0566113	.4962973	-1.298198	1.700719
idx3	643	-1.980747	.6018139	-3.112741	-.8258458

We can obtain the standard error of the index by specifying the `stdp` option:

```
. predict se2, outcome(Prepaid) stdp
(1 missing value generated)

. list p2 idx2 se2 in 1/5
```

	p2	idx2	se2
1.	.3709022	-.4831167	.2437772
2.	.4977667	.055111	.1694686
3.	.4113073	-.1712106	.1793498
4.	.5424927	.3788345	.2513701
5.	.	-.0925817	.1452616

We obtained the probability, `p2`, in the previous example.

Finally, `predict` can calculate the standard error of the difference in the index values between two outcomes with the `stddp` option:

```
. predict se_2_3, outcome(Prepaid,Uninsure) stddp
(1 missing value generated)

. list idx2 idx3 se_2_3 in 1/5
```

	idx2	idx3	se_2_3
1.	-.4831167	-3.073253	.5469354
2.	.055111	-2.715986	.4331918
3.	-.1712106	-1.579621	.3053815
4.	.3788345	-1.462007	.4492552
5.	-.0925817	-2.814022	.4024784

In the first observation, the difference in the indexes is $-0.483 - (-3.073) = 2.59$. The standard error of that difference is 0.547.

◁

▷ Example 3

It is more difficult to interpret the results from `mlogit` than those from `clogit` or `logit` because there are multiple equations. For example, suppose that one of the independent variables in our model takes on the values 0 and 1, and we are attempting to understand the effect of this variable. Assume that the coefficient on this variable for the second outcome, $\beta^{(2)}$, is positive. We might then be tempted to reason that the probability of the second outcome is higher if the variable is 1 rather than 0. Most of the time, that will be true, but occasionally we will be surprised. The probability of some other outcome could increase even more (say, $\beta^{(3)} > \beta^{(2)}$), and thus the probability of outcome 2 would actually fall relative to that outcome. We can use `predict` to help interpret such results.

Continuing with our previously fit insurance-choice model, we wish to describe the model's predictions by race. For this purpose, we can use the method of predictive margins (also known as recycled predictions), in which we vary characteristics of interest across the whole dataset and average the predictions. That is, we have data on both whites and nonwhites, and our individuals have other characteristics as well. We will first pretend that all the people in our data are white but hold their other characteristics constant. We then calculate the probabilities of each outcome. Next we will pretend that all the people in our data are nonwhite, still holding their other characteristics constant. Again we calculate the probabilities of each outcome. The difference in those two sets of calculated probabilities, then, is the difference due to race, holding other characteristics constant.

```
. gen byte nonwhold = nonwhite                  // save real race
. replace nonwhite = 0                          // make everyone white
(126 real changes made)
. predict wpind, outcome(Indemnity)             // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=1                            // make everyone nonwhite
(644 real changes made)
. predict nwpind, outcome(Indemnity)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict nwpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict nwpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=nonwhold                     // restore real race
(518 real changes made)
```

```
. summarize wp* nwp*, sep(3)
```

Variable	Obs	Mean	Std. Dev.	Min	Max
wpind	643	.5141673	.0872679	.3092903	.71939
wpp	643	.4082052	.0993286	.1964103	.6502247
wpnoi	643	.0776275	.0360283	.0273596	.1302816
nwpind	643	.3112809	.0817693	.1511329	.535021
nwpp	643	.630078	.0979976	.3871782	.8278881
nwpnoi	643	.0586411	.0287185	.0209648	.0933874

In example 1 of [R] **mlogit**, we presented a cross-tabulation of insurance type and race. Those values were unadjusted. The means reported above are the values adjusted for age, sex, and site. Combining the results gives

	Unadjusted		Adjusted	
	white	nonwhite	white	nonwhite
Indemnity	0.51	0.36	0.51	0.31
Prepaid	0.42	0.57	0.41	0.63
Uninsured	0.07	0.07	0.08	0.06

We find, for instance, after adjusting for age, sex, and site, that although 57% of nonwhites in our data had prepaid plans, 63% of nonwhites chose prepaid plans.

Computing predictive margins by hand was instructive, but we can compute these values more easily using the `margins` command (see [R] **margins**). The two margins for the indemnity outcome can be estimated by typing

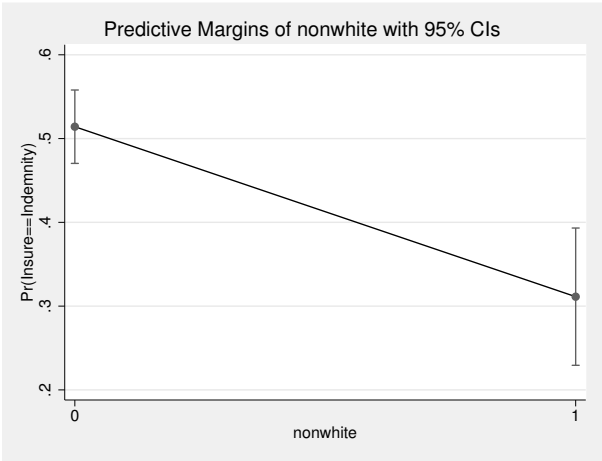
```
. margins nonwhite, predict(outcome(Indemnity)) noesample
Predictive margins                                Number of obs   =        643
Model VCE    : OIM
Expression   : Pr(insure==Indemnity), predict(outcome(Indemnity))
```

	Margin	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
nonwhite						
0	.5141673	.0223485	23.01	0.000	.470365	.5579695
1	.3112809	.0418049	7.45	0.000	.2293448	.393217

`margins` also estimates the standard errors and confidence intervals of the margins. By default, `margins` uses only the estimation sample. We added the `noesample` option so that `margins` would use the entire sample and produce results comparable to our earlier analysis.

We can use `marginsplot` to graph the results from `margins`:

```
. marginsplot
  Variables that uniquely identify margins: nonwhite
```



The margins for the other two outcomes can be computed by typing

```
. margins nonwhite, predict(outcome(Prepaid)) noesample
  (output omitted)
. margins nonwhite, predict(outcome(Uninsure)) noesample
  (output omitted)
```

◁

❑ Technical note

You can use `predict` to classify predicted values and compare them with the observed outcomes to interpret a multinomial logit model. This is a variation on the notions of sensitivity and specificity for logistic regression. Here we will classify indemnity and prepaid as definitely predicting indemnity, definitely predicting prepaid, and ambiguous.

```
. predict indem, outcome(Indemnity) index            // obtain indexes
(1 missing value generated)
. predict prepaid, outcome(Prepaid) index
(1 missing value generated)
. gen diff = prepaid-indem                           // obtain difference
(1 missing value generated)
. predict sediff, outcome(Indemnity,Prepaid) stddp   // & its standard error
(1 missing value generated)
. gen type = 1 if diff/sediff < -1.96                // definitely indemnity
(504 missing values generated)
. replace type = 3 if diff/sediff > 1.96             // definitely prepaid
(100 real changes made)
. replace type = 2 if type>=. & diff/sediff < .      // ambiguous
(404 real changes made)
. label def type 1 "Def Ind" 2 "Ambiguous" 3 "Def Prep"
. label values type type                             // label results
```

```
. tabulate insure type
```

insure	type Def Ind	Ambiguous	Def Prep	Total
Indemnity	78	183	33	294
Prepaid	44	177	56	277
Uninsure	12	28	5	45
Total	134	388	94	616

We can see that the predictive power of this model is modest. There are many misclassifications in both directions, though there are more correctly classified observations than misclassified observations.

Also the uninsured look overwhelmingly as though they might have come from the indemnity system rather than from the prepaid system.

❑

Calculating marginal effects

▷ Example 4

We have already noted that the coefficients from multinomial logit can be difficult to interpret because they are relative to the base outcome. Another way to evaluate the effect of covariates is to examine the marginal effect of changing their values on the probability of observing an outcome.

The `margins` command can be used for this too. We can estimate the marginal effect of each covariate on the probability of observing the first outcome—indemnity insurance—by typing

```
. margins, dydx(*) predict(outcome(Indemnity))
Average marginal effects                        Number of obs   =        615
Model VCE    : OIM
Expression   : Pr(insure==Indemnity), predict(outcome(Indemnity))
dy/dx w.r.t. : age 1.male 1.nonwhite 2.site 3.site
```

	dy/dx	Delta-method Std. Err.	z	P>|z|	[95% Conf.	Interval]
age	.0026655	.001399	1.91	0.057	-.0000765	.0054074
1.male	-.1295734	.0450945	-2.87	0.004	-.2179571	-.0411898
1.nonwhite	-.2032404	.0482554	-4.21	0.000	-.2978192	-.1086616
site						
2	.0070995	.0479993	0.15	0.882	-.0869775	.1011765
3	.1216165	.0505833	2.40	0.016	.022475	.220758

```
Note: dy/dx for factor levels is the discrete change from the base level.
```

By default, `margins` estimates the average marginal effect over the estimation sample, and that is what we see above. Being male decreases the average probability of having indemnity insurance by 0.130. We also see, from the note at the bottom of the table, that the marginal effect was computed as a discrete change in the probability of being male rather than female. That is why we made `male` a factor variable when fitting the model.

The `dydx(*)` option requested that `margins` estimate the marginal effect for each regressor, `dydx(age)` would have produced estimates only for the effect of `age`. `margins` has many options for controlling how the marginal effect is computed, including the ability to average over subgroups or to compute estimates for specified values of the regressors; see [R] **margins**.

We could evaluate the marginal effects on the other two outcomes by typing

```
. margins, dydx(*) predict(outcome(Prepaid))
  (output omitted)
. margins, dydx(*) predict(outcome(Uninsure))
  (output omitted)
```

◁

Testing hypotheses about coefficients

▷ Example 5

`test` tests hypotheses about the coefficients just as after any estimation command; see [R] **test**. Note, however, `test`'s syntax for dealing with multiple-equation models. Because `test` bases its results on the estimated covariance matrix, we might prefer a likelihood-ratio test; see example 5 in [R] **mlogit** for an example of `lrtest`.

If we simply list variables after the `test` command, we are testing that the corresponding coefficients are zero across all equations:

```
. test 2.site 3.site
 ( 1)  [Indemnity]2.site = 0
 ( 2)  [Prepaid]2.site = 0
 ( 3)  [Uninsure]2.site = 0
 ( 4)  [Indemnity]3.site = 0
 ( 5)  [Prepaid]3.site = 0
 ( 6)  [Uninsure]3.site = 0
       Constraint 1 dropped
       Constraint 4 dropped
           chi2(  4) =   19.74
         Prob > chi2 =    0.0006
```

We can test that all the coefficients (except the constant) in an equation are zero by simply typing the outcome in square brackets:

```
. test [Uninsure]
 ( 1)  [Uninsure]age = 0
 ( 2)  [Uninsure]0b.male = 0
 ( 3)  [Uninsure]1.male = 0
 ( 4)  [Uninsure]0b.nonwhite = 0
 ( 5)  [Uninsure]1.nonwhite = 0
 ( 6)  [Uninsure]1b.site = 0
 ( 7)  [Uninsure]2.site = 0
 ( 8)  [Uninsure]3.site = 0
       Constraint 2 dropped
       Constraint 4 dropped
       Constraint 6 dropped
           chi2(  5) =    9.31
         Prob > chi2 =    0.0973
```

We specify the outcome just as we do with `predict`; we can specify the label if the outcome variable is labeled, or we can specify the numeric value of the outcome. We would have obtained the same test as above if we had typed `test [3]` because 3 is the value of `insure` for the outcome uninsured.

We can combine the two syntaxes. To test that the coefficients on the site variables are 0 in the equation corresponding to the outcome prepaid, we can type

```
. test [Prepaid]: 2.site 3.site
 ( 1)  [Prepaid]2.site = 0
 ( 2)  [Prepaid]3.site = 0
           chi2(  2) =   10.78
         Prob > chi2 =    0.0046
```

We specified the outcome and then followed that with a colon and the variables we wanted to test.

We can also test that coefficients are equal across equations. To test that all coefficients except the constant are equal for the prepaid and uninsured outcomes, we can type

```
. test [Prepaid=Uninsure]
 ( 1)  [Prepaid]age - [Uninsure]age = 0
 ( 2)  [Prepaid]0b.male - [Uninsure]0b.male = 0
 ( 3)  [Prepaid]1.male - [Uninsure]1.male = 0
 ( 4)  [Prepaid]0b.nonwhite - [Uninsure]0b.nonwhite = 0
 ( 5)  [Prepaid]1.nonwhite - [Uninsure]1.nonwhite = 0
 ( 6)  [Prepaid]1b.site - [Uninsure]1b.site = 0
 ( 7)  [Prepaid]2.site - [Uninsure]2.site = 0
 ( 8)  [Prepaid]3.site - [Uninsure]3.site = 0
       Constraint 2 dropped
       Constraint 4 dropped
       Constraint 6 dropped
           chi2(  5) =   13.80
         Prob > chi2 =    0.0169
```

To test that only the site variables are equal, we can type

```
. test [Prepaid=Uninsure]: 2.site 3.site
 ( 1)  [Prepaid]2.site - [Uninsure]2.site = 0
 ( 2)  [Prepaid]3.site - [Uninsure]3.site = 0
           chi2(  2) =   12.68
         Prob > chi2 =    0.0018
```

Finally, we can test any arbitrary constraint by simply entering the equation and specifying the coefficients as described in [U] **13.5 Accessing coefficients and standard errors**. The following hypothesis is senseless but illustrates the point:

```
. test ([Prepaid]age+[Uninsure]2.site)/2 = 2-[Uninsure]1.nonwhite
 ( 1)  .5*[Prepaid]age + [Uninsure]1.nonwhite + .5*[Uninsure]2.site = 2
           chi2(  1) =   22.45
         Prob > chi2 =    0.0000
```

See [R] **test** for more information about `test`. The information there about combining hypotheses across `test` commands (the `accumulate` option) also applies after `mlogit`.

Title

more — The —more— message

Syntax

Tell Stata to pause or not pause for —more— messages

```
set more { on | off } [ , permanently ]
```

Set number of lines between —more— messages

```
set pagesize #
```

Description

`set more on`, which is the default, tells Stata to wait until you press a key before continuing when a —more— message is displayed.

`set more off` tells Stata not to pause or display the —more— message.

`set pagesize #` sets the number of lines between —more— messages. The `permanently` option is not allowed with `set pagesize`.

Option

`permanently` specifies that, in addition to making the change right now, the `more` setting be remembered and become the default setting when you invoke Stata.

Remarks

When you see —more— at the bottom of the screen,

Press ...	and Stata ...
letter *l* or *Enter*	displays the next line
letter *q*	acts as if you pressed *Break*
Spacebar or any other key	displays the next screen

You can also click on the **More** button or click on —more— to display the next screen.

—more— is Stata's way of telling you that it has something more to show you but that showing it to you will cause the information on the screen to scroll off.

If you type `set more off`, —more— conditions will never arise, and Stata's output will scroll by at full speed.

If you type `set more on`, —more— conditions will be restored at the appropriate places.

Programmers should see [P] **more** for information on the `more` programming command.

Also see

[R] **query** — Display system parameters

[P] **creturn** — Return c-class values

[P] **more** — Pause until key is pressed

[U] **7 –more– conditions**

Title

mprobit — Multinomial probit regression

Syntax

`mprobit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`noconstant`	suppress constant terms
`baseoutcome(`*#* | *lbl*`)`	outcome used to normalize location
`probitparam`	use the probit variance parameterization
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(`*#*`)`	set confidence level; default is `level(95)`
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Integration	
`intpoints(`*#*`)`	number of quadrature points
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

`bootstrap`, `by`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Categorical outcomes > Independent multinomial probit

Description

`mprobit` fits multinomial probit (MNP) models via maximum likelihood. *depvar* contains the outcome for each observation, and *indepvars* are the associated covariates. The error terms are assumed to be independent, standard normal, random variables. See [R] **asmprobit** for the case where the latent-variable errors are correlated or heteroskedastic and you have alternative-specific variables.

Options

Model

`noconstant` suppresses the $J-1$ constant terms.

`baseoutcome(`*#* | *lbl*`)` specifies the outcome used to normalize the location of the latent variable. The base outcome may be specified as a number or a label. The default is to use the most frequent outcome. The coefficients associated with the base outcome are zero.

`probitparam` specifies to use the probit variance parameterization by fixing the variance of the differenced latent errors between the scale and the base alternatives to be one. The default is to make the variance of the base and scale latent errors one, thereby making the variance of the difference to be two.

`constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

Reporting

`level(#)`; see [R] **estimation options**.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Integration

`intpoints(#)` specifies the number of Gaussian quadrature points to use in approximating the likelihood. The default is 15.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with `mprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms for this implementation of the model are assumed to have independent, standard normal distributions. To use `mprobit`, you must have one observation for each decision maker in the sample. See [R] **asmprobit** for another implementation of the MNP model that permits correlated and heteroskedastic errors and is suitable when you have data for each alternative that a decision maker faced.

The MNP model is frequently motivated using a latent-variable framework. The latent variable for the jth alternative, $j = 1, \ldots, J$, is

$$\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$$

where the $1 \times q$ row vector $\mathbf{z}_i$ contains the observed independent variables for the ith decision maker. Associated with $\mathbf{z}_i$ are the J vectors of regression coefficients $\boldsymbol{\alpha}_j$. The $\xi_{i,1}, \ldots, \xi_{i,J}$ are distributed independently and identically standard normal. The decision maker chooses the alternative k such that $\eta_{ik} \geq \eta_{im}$ for $m \neq k$.

Suppose that case i chooses alternative k, and take the difference between latent variable η_{ik} and the $J - 1$ others:

$$\begin{aligned} v_{ijk} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i \boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned} \tag{1}$$

where $j' = j$ if $j < k$ and $j' = j-1$ if $j > k$ so that $j' = 1, \ldots, J-1$. $\mathrm{Var}(\epsilon_{ij'}) = \mathrm{Var}(\xi_{ij} - \xi_{ik}) = 2$ and $\mathrm{Cov}(\epsilon_{ij'}, \epsilon_{il'}) = 1$ for $j' \neq l'$. The probability that alternative k is chosen is

$$\begin{aligned} \Pr(i \text{ chooses } k) &= \Pr(v_{i1k} \leq 0, \ldots, v_{i,J-1,k} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\mathbf{z}_i \boldsymbol{\gamma}_1, \ldots, \epsilon_{i,J-1} \leq -\mathbf{z}_i \boldsymbol{\gamma}_{J-1}) \end{aligned}$$

Hence, evaluating the likelihood function involves computing probabilities from the multivariate normal distribution. That all the covariances are equal simplifies the problem somewhat; see *Methods and formulas* for details.

In (1), not all J of the $\boldsymbol{\alpha}_j$ are identifiable. To remove the indeterminacy, $\boldsymbol{\alpha}_l$ is set to the zero vector, where l is the base outcome as specified in the `baseoutcome()` option. That fixes the lth latent variable to zero so that the remaining variables measure the attractiveness of the other alternatives relative to the base.

▷ Example 1

As discussed in example 1 of [R] **mlogit**, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan such as an HMO, or the patient may be uninsured. Demographic variables include age, gender, race, and site. Indemnity insurance is the most popular alternative, so `mprobit` will choose it as the base outcome by default.

```

◁

The likelihood function for `mprobit` is derived under the assumption that all decision-making units face the same choice set, which is the union of all outcomes observed in the dataset. If that is not true for your model, then an alternative is to use the `asmprobit` command, which does not require this assumption. To do that, you will need to expand the dataset so that each decision maker has k_i observations, where k_i is the number of alternatives in the choice set faced by decision maker i. You will also need to create a binary variable to indicate the choice made by each decision maker. Moreover, you will need to use the `correlation(independent)` and `stddev(homoskedastic)` options with `asmprobit` unless you have alternative-specific variables.

Saved results

mprobit saves the following in e():

Scalars

e(N)	number of observations
e(k_out)	number of outcomes
e(k_points)	number of quadrature points
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_indvars)	number of independent variables
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(ll)	log simulated-likelihood
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance
e(i_base)	base outcome index
e(const)	0 if noconstant is specified, 1 otherwise
e(probitparam)	1 if probitparam is specified, 0 otherwise
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	mprobit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(indvars)	independent variables
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(chi2type)	Wald, type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(outeqs)	outcome equations
e(out#)	outcome labels, #=1,...,e(k_out)
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(outcomes)	outcome values
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

mprobit is implemented as an ado-file.

See Cameron and Trivedi (2005, chap. 15) for a discussion of multinomial models, including multinomial probit. Long and Freese (2006, chap. 6) discuss the multinomial logistic, multinomial probit, and stereotype logistic regression models, with examples using Stata.

As discussed in *Remarks*, the latent variables for a J-alternative model are $\eta_{ij} = \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$, for $j = 1, \ldots, J$, $i = 1, \ldots, n$, and $\{\xi_{i,1}, \ldots, \xi_{i,\mathrm{J}}\} \sim$ i.i.d.$N(0,1)$. The experimenter observes alternative k for the ith observation if $\eta_{ik} > \eta_{il}$ for $l \neq k$. For $j \neq k$, let

$$\begin{aligned} v_{ij'} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i\boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned}$$

where $j' = j$ if $j < k$ and $j' = j - 1$ if $j > k$ so that $j' = 1, \ldots, J-1$. $\epsilon_i = (\epsilon_{i1}, \ldots, \epsilon_{i,J-1}) \sim MVN(\mathbf{0}, \boldsymbol{\Sigma})$, where

$$\boldsymbol{\Sigma} = \begin{pmatrix} 2 & 1 & 1 & \ldots & 1 \\ 1 & 2 & 1 & \ldots & 1 \\ 1 & 1 & 2 & \ldots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \ldots & 2 \end{pmatrix}$$

Denote the deterministic part of the model as $\lambda_{ij'} = \mathbf{z}_i\boldsymbol{\gamma}_{j'}$; the probability that subject i chooses outcome k is

$$\begin{aligned} \Pr(y_i = k) &= \Pr(v_{i1} \leq 0, \ldots, v_{i,J-1} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\lambda_{i1}, \ldots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) \\ &= \frac{1}{(2\pi)^{(J-1)/2}\,|\boldsymbol{\Sigma}|^{1/2}} \int_{-\infty}^{-\lambda_{i1}} \cdots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\tfrac{1}{2}\mathbf{z}'\boldsymbol{\Sigma}^{-1}\mathbf{z}\right) d\mathbf{z} \end{aligned}$$

Because of the exchangeable correlation structure of $\boldsymbol{\Sigma}$ ($\rho_{ij} = 1/2$ for all $i \neq j$), we can use Dunnett's (1989) result to reduce the multidimensional integral to one dimension:

$$\Pr(y_i = k) = \frac{1}{\sqrt{\pi}} \int_0^{\infty} \left\{ \prod_{j=1}^{J-1} \Phi\left(-z\sqrt{2} - \lambda_{ij}\right) + \prod_{j=1}^{J-1} \Phi\left(z\sqrt{2} - \lambda_{ij}\right) \right\} e^{-z^2} dz$$

Gaussian quadrature is used to approximate this integral, resulting in the K-point quadrature formula

$$\Pr(y_i = k) \approx \frac{1}{2}\sum_{k=1}^{K} w_k \left\{ \prod_{j=1}^{J-1} \Phi\left(-\sqrt{2x_k} - \lambda_{ij}\right) + \prod_{j=1}^{J-1} \Phi\left(\sqrt{2x_k} - \lambda_{ij}\right) \right\}$$

where w_k and x_k are the weights and roots of the Laguerre polynomial of order K. In `mprobit`, K is specified by the `intpoints()` option.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

mprobit postestimation — Postestimation tools for mprobit

Description

The following postestimation commands are available after `mprobit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predicted probabilities, linear predictions, and standard errors
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

`predict` [*type*] { *stub*`*` | *newvar* | *newvarlist* } [*if*] [*in*] [`,` *statistic* `outcome(`*outcome*`)`]

`predict` [*type*] { *stub*`*` | *newvarlist* } [*if*] [*in*]`, scores`

statistic	Description
Main	
`pr`	probability of a positive outcome; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction

If you do not specify `outcome()`, `pr` (with one new variable specified), `xb`, and `stdp` assume `outcome(#1)`.
You specify one or k new variables with `pr`, where k is the number of outcomes.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of each of the categories of the dependent variable or the probability of the level specified in `outcome(`*outcome*`)`. If you specify the `outcome(`*outcome*`)` option, you need to specify only one new variable; otherwise, you must specify a new variable for each category of the dependent variable.

`xb` calculates the linear prediction, $\mathbf{x}_i\boldsymbol{\alpha}_j$, for alternative j and individual i. The index, j, corresponds to the outcome specified in `outcome()`.

`stdp` calculates the standard error of the linear prediction.

`outcome(`*outcome*`)` specifies the outcome for which the statistic is to be calculated. `equation()` is a synonym for `outcome()`: it does not matter which you use. `outcome()` or `equation()` can be specified using

`#1`, `#2`, ..., where `#1` means the first category of the dependent variable, `#2` means the second category, etc.;

the values of the dependent variable; or

the value labels of the dependent variable if they exist.

`scores` calculates the equation-level score variables. The jth new variable will contain the scores for the jth fitted equation.

Remarks

Once you have fit a multinomial probit model, you can use `predict` to obtain probabilities that an individual will choose each of the alternatives for the estimation sample, as well as other samples; see [U] **20 Estimation and postestimation commands** and [R] **predict**.

▷ Example 1

In example 1 of [R] **mprobit**, we fit the multinomial probit model to a dataset containing the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). We can obtain the predicted probabilities by typing

```
. use http://www.stata-press.com/data/r12/sysdsn1
(Health insurance data)
. mprobit insure age male nonwhite i.site
  (output omitted)
. predict p1-p3
(option pr assumed; predicted probabilities)
```

```
. list p1-p3 insure in 1/10
```

	p1	p2	p3	insure
1.	.5961306	.3741824	.029687	Indemnity
2.	.4719296	.4972289	.0308415	Prepaid
3.	.4896086	.4121961	.0981953	Indemnity
4.	.3730529	.5416623	.0852848	Prepaid
5.	.5063069	.4629773	.0307158	.
6.	.4768125	.4923548	.0308327	Prepaid
7.	.5035672	.4657016	.0307312	Prepaid
8.	.3326361	.5580404	.1093235	.
9.	.4758165	.4384811	.0857024	Uninsure
10.	.5734057	.3316601	.0949342	Prepaid

`insure` contains a missing value for observations 5 and 8. Because of that, those two observations were not used in the estimation. However, because none of the independent variables is missing, `predict` can still calculate the probabilities. Had we typed

```
. predict p1-p3 if e(sample)
```

`predict` would have filled in missing values for `p1`, `p2`, and `p3` for those observations because they were not used in the estimation.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

mvreg — Multivariate regression

Syntax

`mvreg` *depvars* `=` *indepvars* [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`noconstant`	suppress constant term
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`corr`	report correlation matrix
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
`noheader`	suppress header table from above coefficient table
`notable`	suppress coefficient table
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.
depvars and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`bootstrap`, `by`, `jackknife`, `mi estimate`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.
`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.
`noheader`, `notable`, and `coeflegend` do not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Multiple-equation models > Multivariate regression

Description

`mvreg` fits multivariate regression models.

Options

Model

`noconstant` suppresses the constant term (intercept) in the model.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`corr` displays the correlation matrix of the residuals between the equations.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

The following options are available with mvreg but are not shown in the dialog box:

noheader suppresses display of the table reporting F statistics, R-squared, and root mean squared error above the coefficient table.

notable suppresses display of the coefficient table.

coeflegend; see [R] **estimation options**.

Remarks

Multivariate regression differs from multiple regression in that *several* dependent variables are jointly regressed on the same independent variables. Multivariate regression is related to Zellner's seemingly unrelated regression (see [R] **sureg**), but because the same set of independent variables is used for each dependent variable, the syntax is simpler, and the calculations are faster.

The individual coefficients and standard errors produced by mvreg are identical to those that would be produced by regress estimating each equation separately. The difference is that mvreg, being a joint estimator, also estimates the between-equation covariances, so you can test coefficients across equations and, in fact, the test syntax makes such tests more convenient.

▷ Example 1

Using the automobile data, we fit a multivariate regression for space variables (headroom, trunk, and turn) in terms of a set of other variables, including three performance variables (displacement, gear_ratio, and mpg):

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. mvreg headroom trunk turn = price mpg displ gear_ratio length weight
Equation          Obs  Parms        RMSE    "R-sq"          F        P
------------------------------------------------------------------------
headroom           74      7    .7390205    0.2996   4.777213   0.0004
trunk              74      7    3.052314    0.5326    12.7265   0.0000
turn               74      7    2.132377    0.7844   40.62042   0.0000

------------------------------------------------------------------------------
             |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
headroom     |
       price |  -.0000528    .000038    -1.39   0.168    -.0001286    .0000229

      weight |   .0027059    .001363     1.99   0.051    -.0000145    .0054264
       _cons |   20.19157   6.261549     3.22   0.002     7.693467    32.68968
------------------------------------------------------------------------------
```

We should have specified the `corr` option so that we would also see the correlations between the residuals of the equations. We can correct our omission because `mvreg`—like all estimation commands—typed without arguments redisplays results. The `noheader` and `notable` (read "no-table") options suppress redisplaying the output we have already seen:

```
. mvreg, notable noheader corr
Correlation matrix of residuals:

             headroom     trunk      turn
headroom       1.0000
   trunk       0.4986    1.0000
    turn      -0.1090   -0.0628    1.0000

Breusch-Pagan test of independence: chi2(3) =    19.566, Pr = 0.0002
```

The Breusch–Pagan test is significant, so the residuals of these three space variables are not independent of each other.

The three performance variables among our independent variables are `mpg`, `displacement`, and `gear_ratio`. We can jointly test the significance of these three variables in all the equations by typing

```
. test mpg displacement gear_ratio
 ( 1)  [headroom]mpg = 0
 ( 2)  [trunk]mpg = 0
 ( 3)  [turn]mpg = 0
 ( 4)  [headroom]displacement = 0
 ( 5)  [trunk]displacement = 0
 ( 6)  [turn]displacement = 0
 ( 7)  [headroom]gear_ratio = 0
 ( 8)  [trunk]gear_ratio = 0
 ( 9)  [turn]gear_ratio = 0
       F(  9,    67) =    0.33
            Prob > F =    0.9622
```

These three variables are not, as a group, significant. We might have suspected this from their individual significance in the individual regressions, but this multivariate test provides an overall assessment with one p-value.

We can also perform a test for the joint significance of all three equations:

```
. test [headroom]
 (output omitted)
. test [trunk], accum
 (output omitted)
. test [turn], accum
 ( 1)  [headroom]price = 0
 ( 2)  [headroom]mpg = 0
 ( 3)  [headroom]displacement = 0
 ( 4)  [headroom]gear_ratio = 0
 ( 5)  [headroom]length = 0
 ( 6)  [headroom]weight = 0
 ( 7)  [trunk]price = 0
 ( 8)  [trunk]mpg = 0
 ( 9)  [trunk]displacement = 0
 (10)  [trunk]gear_ratio = 0
 (11)  [trunk]length = 0
 (12)  [trunk]weight = 0
 (13)  [turn]price = 0
 (14)  [turn]mpg = 0
 (15)  [turn]displacement = 0
 (16)  [turn]gear_ratio = 0
 (17)  [turn]length = 0
 (18)  [turn]weight = 0
       F( 18,    67) =   19.34
            Prob > F =    0.0000
```

The set of variables as a whole is strongly significant. We might have suspected this, too, from the individual equations.

◁

❑ Technical note

The `mvreg` command provides a good way to deal with multiple comparisons. If we wanted to assess the effect of `length`, we might be dissuaded from interpreting any of its coefficients except that in the `trunk` equation. `[trunk]length`—the coefficient on `length` in the `trunk` equation—has a p-value of 0.002, but in the other two equations, it has p-values of only 0.224 and 0.058.

A conservative statistician might argue that there are 18 tests of significance in `mvreg`'s output (not counting those for the intercept), so p-values more than $0.05/18 = 0.0028$ should be declared

insignificant at the 5% level. A more aggressive but, in our opinion, reasonable approach would be to first note that the three equations are jointly significant, so we are justified in making some interpretation. Then we would work through the individual variables using `test`, possibly using $0.05/6 = 0.0083$ (6 because there are six independent variables) for the 5% significance level. For instance, examining `length`:

```
. test length
 ( 1)  [headroom]length = 0
 ( 2)  [trunk]length = 0
 ( 3)  [turn]length = 0
       F(  3,    67) =    4.94
            Prob > F =    0.0037
```

The reported significance level of 0.0037 is less than 0.0083, so we will declare this variable significant. `[trunk]length` is certainly significant with its p-value of 0.002, but what about in the remaining two equations with p-values 0.224 and 0.058? We perform a joint test:

```
. test [headroom]length [turn]length
 ( 1)  [headroom]length = 0
 ( 2)  [turn]length = 0
       F(  2,    67) =    2.91
            Prob > F =    0.0613
```

At this point, reasonable statisticians could disagree. The 0.06 significance value suggests no interpretation, but these were the two least-significant values out of three, so we would expect the p-value to be a little high. Perhaps an equivocal statement is warranted: there seems to be an effect, but chance cannot be excluded.

❑

Saved results

mvreg saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters in each equation
e(k_eq)	number of equations in e(b)
e(df_r)	residual degrees of freedom
e(chi2)	Breusch–Pagan χ^2 (corr only)
e(df_chi2)	degrees of freedom for Breusch–Pagan χ^2 (corr only)
e(rank)	rank of e(V)

Macros

e(cmd)	mvreg
e(cmdline)	command as typed
e(depvar)	names of dependent variables
e(eqnames)	names of equations
e(wtype)	weight type
e(wexp)	weight expression
e(r2)	R-squared for each equation
e(rmse)	RMSE for each equation
e(F)	F statistic for each equation
e(p_F)	significance of F for each equation
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Sigma)	$\widehat{\mathbf{\Sigma}}$ matrix
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

Methods and formulas

mvreg is implemented as an ado-file.

Given q equations and p independent variables (including the constant), the parameter estimates are given by the $p \times q$ matrix

$$\mathbf{B} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$$

where $\mathbf{Y}$ is an $n \times q$ matrix of dependent variables and $\mathbf{X}$ is a $n \times p$ matrix of independent variables. $\mathbf{W}$ is a weighting matrix equal to $\mathbf{I}$ if no weights are specified. If weights are specified, let $\mathbf{v}$: $1 \times n$ be the specified weights. If fweight frequency weights are specified, $\mathbf{W} = \text{diag}(\mathbf{v})$. If aweight analytic weights are specified, $\mathbf{W} = \text{diag}\{\mathbf{v}/(\mathbf{1}'\mathbf{v})(\mathbf{1}'\mathbf{1})\}$, meaning that the weights are normalized to sum to the number of observations.

The residual covariance matrix is

$$\mathbf{R} = \{\mathbf{Y}'\mathbf{W}\mathbf{Y} - \mathbf{B}'(\mathbf{X}'\mathbf{W}\mathbf{X})\mathbf{B}\}/(n-p)$$

The estimated covariance matrix of the estimates is $\mathbf{R} \otimes (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$. These results are identical to those produced by sureg when the same list of independent variables is specified repeatedly; see [R] **sureg**.

The Breusch and Pagan (1980) χ^2 statistic—a Lagrange multiplier statistic—is given by

$$\lambda = n \sum_{i=1}^{q} \sum_{j=1}^{i-1} r_{ij}^2$$

where r_{ij} is the estimated correlation between the residuals of the equations and n is the number of observations. It is distributed as χ^2 with $q(q-1)/2$ degrees of freedom.

Title

mvreg postestimation — Postestimation tools for mvreg

Description

The following postestimation commands are available after `mvreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	VCE and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` `equation(`*eqno*[`,` *eqno*]`)` *statistic*]

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the linear prediction
`residuals`	residuals
`difference`	difference between the linear predictions of two equations
`stddp`	standard error of the difference in linear predictions

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`equation(`*eqno*[`,` *eqno*]`)` specifies the equation to which you are referring.

`equation()` is filled in with one *eqno* for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)`, to the equation named hours.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

`difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required. With `equation(#1,#2)`, `difference` computes the prediction of `equation(#1)` minus the prediction of `equation(#2)`.

`xb`, the default, calculates the fitted values—the prediction of $\mathbf{x}_j\mathbf{b}$ for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation (the standard error of the predicted expected value or mean for the observation's covariate pattern). The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.

`difference` calculates the difference between the linear predictions of two equations in the system.

`stddp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions $(\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b})$ between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [R] **predict**.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

nbreg — Negative binomial regression

Syntax

Negative binomial regression model

`nbreg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *nbreg_options*]

Generalized negative binomial model

`gnbreg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *gnbreg_options*]

nbreg_options	Description
Model	
`noconstant`	suppress constant term
`dispersion(mean)`	parameterization of dispersion; `dispersion(mean)` is the default
`dispersion(constant)`	constant dispersion for all observations
`exposure(`*varname*$_e$`)`	include ln(*varname*$_e$) in model with coefficient constrained to 1
`offset(`*varname*$_o$`)`	include *varname*$_o$ in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `opg`, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`nolrtest`	suppress likelihood-ratio test
`irr`	report incidence-rate ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

gnbreg_options	Description
Model	
noconstant	suppress constant term
lnalpha(*varlist*)	dispersion model variables
exposure(*varname*$_e$)	include ln(*varname*$_e$) in model with coefficient constrained to 1
offset(*varname*$_o$)	include *varname*$_o$ in model with coefficient constrained to 1
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, opg, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
irr	report incidence-rate ratios
nocnsreport	do not display constraints

gnbreg

Statistics > Count outcomes > Generalized negative binomial regression

Description

`nbreg` fits a negative binomial regression model of *depvar* on *indepvars*, where *depvar* is a nonnegative count variable. In this model, the count variable is believed to be generated by a Poisson-like process, except that the variation is greater than that of a true Poisson. This extra variation is referred to as overdispersion. See [R] **poisson** before reading this entry.

`gnbreg` fits a generalization of the negative binomial mean-dispersion model; the shape parameter α may also be parameterized.

If you have panel data, see [XT] **xtnbreg**.

Options for nbreg

Model

`noconstant`; see [R] **estimation options**.

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to $1+\alpha\exp(\mathbf{x}_j\boldsymbol{\beta}+\text{offset}_j)$; that is, the dispersion is a function of the expected mean: $\exp(\mathbf{x}_j\boldsymbol{\beta}+\text{offset}_j)$. `dispersion(constant)` has dispersion equal to $1+\delta$; that is, it is a constant for all observations.

`exposure(`*varname*$_e$`)`, `offset(`*varname*$_o$`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`nolrtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following option is available with nbreg but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Options for gnbreg

Model

noconstant; see [R] **estimation options**.

lnalpha(*varlist*) allows you to specify a linear equation for $\ln\alpha$. Specifying lnalpha(male old) means that $\ln\alpha = \gamma_0 + \gamma_1$male $+ \gamma_2$old, where γ_0, γ_1, and γ_2 are parameters to be estimated along with the other model coefficients. If this option is not specified, gnbreg and nbreg will produce the same results because the shape parameter will be parameterized as a constant.

exposure(*varname*$_e$), offset(*varname*$_o$), constraints(*constraints*), collinear; see [R] **estimation options**.

SE/Robust

vce(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

level(#); see [R] **estimation options**.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default *vcetype* to vce(opg).

The following option is available with gnbreg but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction to negative binomial regression
nbreg
gnbreg

Introduction to negative binomial regression

Negative binomial regression models the number of occurrences (counts) of an event when the event has extra-Poisson variation, that is, when it has overdispersion. The Poisson regression model is

$$y_j \sim \text{Poisson}(\mu_j)$$

where

$$\mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$$

for observed counts y_j with covariates $\mathbf{x}_j$ for the jth observation. One derivation of the negative binomial mean-dispersion model is that individual units follow a Poisson regression model, but there is an omitted variable ν_j, such that e^{ν_j} follows a gamma distribution with mean 1 and variance α:

$$y_j \sim \text{Poisson}(\mu_j^*)$$

where

$$\mu_j^* = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j + \nu_j)$$

and

$$e^{\nu_j} \sim \text{Gamma}(1/\alpha, \alpha)$$

With this parameterization, a Gamma(a, b) distribution will have expectation ab and variance ab^2.

We refer to α as the overdispersion parameter. The larger α is, the greater the overdispersion. The Poisson model corresponds to $\alpha = 0$. `nbreg` parameterizes α as $\ln\alpha$. `gnbreg` allows $\ln\alpha$ to be modeled as $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$, a linear combination of covariates $\mathbf{z}_j$.

`nbreg` will fit two different parameterizations of the negative binomial model. The default, described above and also given by the `dispersion(mean)` option, has dispersion for the jth observation equal to $1 + \alpha\exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$. This is seen by noting that the above implies that

$$\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$$

and thus

$$\begin{aligned}\text{Var}(y_j) &= E\left\{\text{Var}(y_j|\mu_j^*)\right\} + \text{Var}\left\{E(y_j|\mu_j^*)\right\} \\ &= E(\mu_j^*) + \text{Var}(\mu_j^*) \\ &= \mu_j(1 + \alpha\mu_j)\end{aligned}$$

The alternative parameterization, given by the `dispersion(constant)` option, has dispersion equal to $1 + \delta$; that is, it is constant for all observations. This is so because the constant-dispersion model assumes instead that

$$\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$$

and thus $\text{Var}(y_j) = \mu_j(1 + \delta)$. The Poisson model corresponds to $\delta = 0$.

For detailed derivations of both models, see Cameron and Trivedi (1998, 70–77). In particular, note that the mean-dispersion model is known as the NB2 model in their terminology, whereas the constant-dispersion model is referred to as the NB1 model.

See Long and Freese (2006) and Cameron and Trivedi (2010, chap. 17) for a discussion of the negative binomial regression model with Stata examples and for a discussion of other regression models for count data.

Hilbe (2011) provides an extensive review of the negative binomial model and its variations, using Stata examples.

nbreg

It is not uncommon to posit a Poisson regression model and observe a lack of model fit. The following data appeared in Rodríguez (1993):

```

        Prob > chi2(18)          =    0.0000
```

The extreme significance of the goodness-of-fit χ^2 indicates that the Poisson regression model is inappropriate, suggesting to us that we should try a negative binomial model:

```

```
Likelihood-ratio test of alpha=0:  chibar2(01) = 4056.27 Prob>=chibar2 = 0.000
```

Our original Poisson model is a special case of the negative binomial—it corresponds to $\alpha = 0$. `nbreg`, however, estimates α indirectly, estimating instead $\ln\alpha$. In our model, $\ln\alpha = 0.594$, meaning that $\alpha = 1.81$ (`nbreg` undoes the transformation for us at the bottom of the output).

To test $\alpha = 0$ (equivalent to $\ln\alpha = -\infty$), `nbreg` performs a likelihood-ratio test. The staggering χ^2 value of 4,056 asserts that the probability that we would observe these data conditional on $\alpha = 0$ is virtually zero, that is, conditional on the process being Poisson. The data are not Poisson. It is not accidental that this χ^2 value is close to the goodness-of-fit statistic from the Poisson regression itself.

❑ Technical note

The usual Gaussian test of $\alpha = 0$ is omitted because this test occurs on the boundary, invalidating the usual theory associated with such tests. However, the likelihood-ratio test of $\alpha = 0$ has been modified to be valid on the boundary. In particular, the null distribution of the likelihood-ratio test statistic is not the usual χ^2_1, but rather a 50:50 mixture of a χ^2_0 (point mass at zero) and a χ^2_1, denoted as $\overline{\chi}^2_{01}$. See Gutierrez, Carter, and Drukker (2001) for more details. ❑

❑ Technical note

The negative binomial model deals with cases in which there is more variation than would be expected if the process were Poisson. The negative binomial model is not helpful if there is less than Poisson variation—if the variance of the count variable is less than its mean. However, underdispersion is uncommon. Poisson models arise because of independently generated events. Overdispersion comes about if some of the parameters (causes) of the Poisson processes are unknown. To obtain underdispersion, the sequence of events somehow would have to be regulated; that is, events would not be independent but controlled based on past occurrences. ❑

gnbreg

`gnbreg` is a generalization of `nbreg`, `dispersion(mean)`. Whereas in `nbreg`, one $\ln\alpha$ is estimated, `gnbreg` allows $\ln\alpha$ to vary, observation by observation, as a linear combination of another set of covariates: $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$.

We will assume that the number of deaths is a function of age, whereas the $\ln\alpha$ parameter is a function of cohort. To fit the model, we type

```
. gnbreg deaths age_mos, lnalpha(i.cohort) offset(logexp)
Fitting constant-only model:
Iteration 0:   log likelihood =   -187.067  (not concave)
Iteration 1:   log likelihood =  -137.4064

       _cons |  -.4759581   .5156502    -0.92   0.356    -1.486614    .5346978
------------------------------------------------------------------------------
```

We find that age is a significant determinant of the number of deaths. The standard errors for the variables in the $\ln\alpha$ equation suggest that the overdispersion parameter does not vary across cohorts. We can test this assertion by typing

```
. test 2.cohort 3.cohort
 ( 1)  [lnalpha]2.cohort = 0
 ( 2)  [lnalpha]3.cohort = 0
           chi2(  2) =    0.02
         Prob > chi2 =    0.9904
```

There is no evidence of variation by cohort in these data.

❑ Technical note

Note the intentional absence of a likelihood-ratio test for $\alpha = 0$ in gnbreg. The test is affected by the same boundary condition that affects the comparison test in nbreg; however, when α is parameterized by more than a constant term, the null distribution becomes intractable. For this reason, we recommend using nbreg to test for overdispersion and, if you have reason to believe that overdispersion exists, only then modeling the overdispersion using gnbreg.

❑

Methods and formulas

nbreg and gnbreg are implemented as ado-files.

See [R] **poisson** and Johnson, Kemp, and Kotz (2005, chap. 4) for an introduction to the Poisson distribution.

Methods and formulas are presented under the following headings:

Mean-dispersion model
Constant-dispersion model

Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times something occurs, y_j, is distributed as Poisson$(\nu_j\mu_j)$. That is, its conditional likelihood is

$$f(y_j \mid \nu_j) = \frac{(\nu_j\mu_j)^{y_j} e^{-\nu_j\mu_j}}{\Gamma(y_j+1)}$$

where $\mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ and ν_j is an unobserved parameter with a Gamma$(1/\alpha, \alpha)$ density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha}\Gamma(1/\alpha)}$$

This gamma distribution has mean 1 and variance α, where α is our ancillary parameter.

The unconditional likelihood for the jth observation is therefore

$$f(y_j) = \int_0^\infty f(y_j \mid \nu) g(\nu)\, d\nu = \frac{\Gamma(m+y_j)}{\Gamma(y_j+1)\Gamma(m)}\, p_j^m (1-p_j)^{y_j}$$

where $p_j = 1/(1+\alpha\mu_j)$ and $m = 1/\alpha$. Solutions for α are handled by searching for $\ln\alpha$ because α must be greater than zero.

The log likelihood (with weights w_j and offsets) is given by

$$m = 1/\alpha \qquad p_j = 1/(1+\alpha\mu_j) \qquad \mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$$

$$\ln L = \sum_{j=1}^{n} w_j \Big[\ln\{\Gamma(m+y_j)\} - \ln\{\Gamma(y_j+1)\} - \ln\{\Gamma(m)\} + m\ln(p_j) + y_j\ln(1-p_j) \Big]$$

For gnbreg, α can vary across the observations according to the parameterization $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$.

Constant-dispersion model

The constant-dispersion model assumes that y_j is conditionally distributed as Poisson(μ_j^*), where $\mu_j^* \sim$ Gamma$(\mu_j/\delta, \delta)$ for some dispersion parameter δ (by contrast, the mean-dispersion model assumes that $\mu_j^* \sim$ Gamma$(1/\alpha, \alpha\mu_j)$). The log likelihood is given by

$$m_j = \mu_j/\delta \qquad p = 1/(1+\delta)$$

$$\ln L = \sum_{j=1}^{n} w_j \Big[\ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1-p) \Big]$$

with everything else defined as before in the calculations for the mean-dispersion model.

`nbreg` and `gnbreg` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

nbreg postestimation — Postestimation tools for nbreg and gnbreg

Description

The following postestimation commands are available after `nbreg` and `gnbreg`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat (svy)`.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]

predict [type] {stub* | newvar_reg newvar_disp} [if] [in], scores
```

statistic	Description
Main	
`n`	number of events; the default
`ir`	incidence rate (equivalent to `predict ..., n nooffset`)
`pr(`*n*`)`	probability $\Pr(y_j = n)$
`pr(`*a*`,`*b*`)`	probability $\Pr(a \leq y_j \leq b)$
`xb`	linear prediction
`stdp`	standard error of the linear prediction

In addition, relevant only after gnbreg are the following:

statistic	Description
Main	
alpha	predicted values of α_j
lnalpha	predicted values of $\ln\alpha_j$
stdplna	standard error of predicted $\ln\alpha_j$

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

n, the default, calculates the predicted number of events, which is $\exp(\mathbf{x}_j\boldsymbol{\beta})$ if neither offset(*varname*$_o$) nor exposure(*varname*$_e$) was specified when the model was fit; $\exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ if offset() was specified; or $\exp(\mathbf{x}_j\boldsymbol{\beta}) \times \text{exposure}_j$ if exposure() was specified.

ir calculates the incidence rate $\exp(\mathbf{x}_j\boldsymbol{\beta})$, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.

pr(*n*) calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable.

pr(*a*,*b*) calculates the probability $\Pr(a \leq y_j \leq b)$, where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

b missing ($b \geq .$) means $+\infty$;
pr(20,.) calculates $\Pr(y_j \geq 20)$;
pr(20,*b*) calculates $\Pr(y_j \geq 20)$ in observations for which $b \geq .$ and calculates $\Pr(20 \leq y_j \leq b)$ elsewhere.

pr(.,*b*) produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for pr(*a*,*b*).

xb calculates the linear prediction, which is $\mathbf{x}_j\boldsymbol{\beta}$ if neither offset() nor exposure() was specified; $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$ if offset() was specified; or $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ if exposure() was specified; see nooffset below.

stdp calculates the standard error of the linear prediction.

alpha, lnalpha, and stdplna are relevant after gnbreg estimation only; they produce the predicted values of α_j, $\ln\alpha_j$, and the standard error of the predicted $\ln\alpha_j$, respectively.

nooffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\boldsymbol{\beta}$ rather than as $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$ or $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$. Specifying predict ..., nooffset is equivalent to specifying predict ..., ir.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L/\partial(\ln\alpha_j)$ for `dispersion(mean)` and `gnbreg`.

The second new variable will contain $\partial \ln L/\partial(\ln\delta)$ for `dispersion(constant)`.

Remarks

After `nbreg` and `gnbreg`, `predict` returns the expected number of deaths per cohort and the probability of observing the number of deaths recorded or fewer.

```
. use http://www.stata-press.com/data/r12/rod93
. nbreg deaths i.cohort, nolog
Negative binomial regression                    Number of obs   =         21
                                                LR chi2(2)      =       0.14
Dispersion     = mean                           Prob > chi2     =     0.9307
Log likelihood = -108.48841                     Pseudo R2       =     0.0007

Likelihood-ratio test of alpha=0:  chibar2(01) =  434.62 Prob>=chibar2 = 0.000
. predict count
(option n assumed; predicted number of events)
. predict p, pr(0, deaths)
. summarize deaths count p
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
      deaths |         21    84.66667    48.84192        10        197
       count |         21    84.66667     4.00773        80   89.57143
           p |         21    .4991542    .2743702   .0070255   .9801285
```

The expected number of deaths ranges from 80 to 90. The probability $\Pr(y_i \leq \texttt{deaths})$ ranges from 0.007 to 0.98.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

In the following, we use the same notation as in [R] **nbreg**.

Methods and formulas are presented under the following headings:

Mean-dispersion model
Constant-dispersion model

Mean-dispersion model

The equation-level scores are given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = p_j(y_j - \mu_j)$$
$$\text{score}(\tau)_j = -m\left\{\frac{\alpha_j(\mu_j - y_j)}{1+\alpha_j\mu_j} - \ln(1+\alpha_j\mu_j) + \psi(y_j+m) - \psi(m)\right\}$$

where $\tau_j = \ln\alpha_j$ and $\psi(z)$ is the digamma function.

Constant-dispersion model

The equation-level scores are given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = m_j\{\psi(y_j+m_j) - \psi(m_j) + \ln(p)\}$$
$$\text{score}(\tau)_j = y_j - (y_j+m_j)(1-p) - \text{score}(\mathbf{x}\boldsymbol{\beta})_j$$

where $\tau_j = \ln\delta_j$.

Title

nestreg — Nested model statistics

Syntax

Standard estimation command syntax

```
nestreg [ , options ]: command_name depvar (varlist) [ (varlist) ... ]
    [ if ] [ in ] [ weight ] [ command_options ]
```

Survey estimation command syntax

```
nestreg [ , options ]: svy [ vcetype ] [ , svy_options ]: command_name depvar
    (varlist) [ (varlist) ... ] [ if ] [ in ] [ , command_options ]
```

options	Description
Reporting	
`waldtable`	report Wald test results; the default
`lrtable`	report likelihood-ratio test results
`quietly`	suppress any output from *command_name*
`store(`*stub*`)`	store nested estimation results in `_est_`*stub#*

`by` is allowed; see [U] **11.1.10 Prefix commands**.

Weights are allowed if *command_name* allows them; see [U] **11.1.6 weight**.

A *varlist* in parentheses indicates that this list of variables is to be considered as a block. Each variable in a *varlist* not bound in parentheses will be treated as its own block.

All postestimation commands behave as they would after *command_name* without the `nestreg` prefix; see the postestimation manual entry for *command_name*.

Menu

Statistics > Other > Nested model statistics

Description

`nestreg` fits nested models by sequentially adding blocks of variables and then reports comparison tests between the nested models.

Options

Reporting

`waldtable` specifies that the table of Wald test results be reported. `waldtable` is the default.

`lrtable` specifies that the table of likelihood-ratio tests be reported. This option is not allowed if `pweights`, the `vce(robust)` option, or the `vce(cluster` *clustvar*`)` option is specified. `lrtable` is also not allowed with the `svy` prefix.

`quietly` suppresses the display of any output from *command_name*.

store(*stub*) specifies that each model fit by nestreg be stored under the name _est_*stub*#, where # is the nesting order from first to last.

Remarks

Remarks are presented under the following headings:

Estimation commands
Wald tests
Likelihood-ratio tests
Programming for nestreg

Estimation commands

nestreg removes collinear predictors and observations with missing values from the estimation sample before calling *command_name*.

The following Stata commands are supported by nestreg:

clogit	nbreg	regress
cloglog	ologit	scobit
glm	oprobit	stcox
intreg	poisson	stcrreg
logistic	probit	streg
logit	qreg	tobit

You do not supply a *depvar* for stcox, stcrreg, or streg; otherwise, *depvar* is required. You must supply two *depvar*s for intreg.

Wald tests

Use nestreg to test the significance of blocks of predictors, building the regression model one block at a time. Using the data from example 1 of [R] **test**, we wish to test the significance of the following predictors of birth rate: medage, medagesq, and region (already partitioned into four indicator variables: reg1, reg2, reg3, and reg4).

```
. use http://www.stata-press.com/data/r12/census4

```

`nestreg` collected the F statistic for the corresponding block of predictors and the model R^2 statistic from each model fit.

The F statistic for the first block, 164.72, is for a test of the joint significance of the first block of variables; it is simply the F statistic from the regression of `brate` on `medage`. The F statistic for the second block, 35.25, is for a test of the joint significance of the second block of variables in a regression of both the first and second blocks of variables. In our example, it is an F test of `medagesq` in the regression of `brate` on `medage` and `medagesq`. Similarly, the third block's F statistic of 8.85 corresponds to a joint test of `reg2`, `reg3`, and `reg4` in the final regression.

Likelihood-ratio tests

The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; also see `lrtest`. Using the data from example 1 of [R] **lrtest**, we wish to jointly test the significance of the following predictors of low birthweight: `age`, `lwt`, `ptl`, and `ht`.

```
. use http://www.stata-press.com/data/r12/lbw

2	-100.724	14.42	4	0.0061	219.448	248.6237

The estimation results from the full model are left in `e()`, so we can later use `estat` and other postestimation commands.

```
. estat gof
Logistic model for low, goodness-of-fit test
       number of observations =       189
 number of covariate patterns =       182
           Pearson chi2(173) =       179.24
                 Prob > chi2 =         0.3567
```

Programming for nestreg

If you want your user-written command (*command_name*) to work with `nestreg`, it must follow standard Stata syntax and allow the `if` qualifier. Furthermore, *command_name* must have `sw` or `swml` as a program property; see [P] **program properties**. If *command_name* has `swml` as a property, *command_name* must save the log-likelihood value in `e(ll)` and the model degrees of freedom in `e(df_m)`.

Saved results

`nestreg` saves the following in `r()`:

Matrices

`r(wald)`	matrix corresponding to the Wald table
`r(lr)`	matrix corresponding to the likelihood-ratio table

Methods and formulas

`nestreg` is implemented as an ado-file.

Acknowledgment

We thank Paul H. Bern, Syracuse University, for developing the hierarchical regression command that inspired `nestreg`.

	or	`SITE`

Description

`net` downloads and installs additions to Stata. The additions can be obtained from the Internet or from physical media. The additions can be ado-files (new commands), help files, or even datasets. Collections of files are bound together into *packages*. For instance, the package named zz49 might add the `xyz` command to Stata. At a minimum, such a package would contain `xyz.ado`, the code to implement the new command, and `xyz.sthlp`, the online help to describe it. That the package contains two files is a detail: you use `net` to download the package zz49, regardless of the number of files.

`ado` manages the packages you have installed by using `net`. The `ado` command lets you list and uninstall previously installed packages.

You can also access the `net` and `ado` features by selecting **Help > SJ and User-written Programs**; this is the recommended method to find and install additions to Stata.

Options

`all` is used with `net install` and `net get`. Typing it with either one makes the command equivalent to typing `net install` followed by `net get`.

`replace` is for use with `net install` and `net get`. It specifies that the downloaded files replace existing files if any of the files already exists.

`force` specifies that the downloaded files replace existing files if any of the files already exists, even if Stata thinks all the files are the same. `force` implies `replace`.

`find(`*string*`)` is for use with `ado`, `ado dir`, and `ado describe`. It specifies that the descriptions of the packages installed on your computer be searched, and that the package descriptions containing *string* be listed.

`from(`*dirname*`)`, when used with `ado`, specifies where the packages are installed. The default is `from(PLUS)`. `PLUS` is a code word that Stata understands to correspond to a particular directory on your computer that was set at installation time. On Windows computers, `PLUS` probably means the directory `c:\ado\plus`, but it might mean something else. You can find out what it means by typing `sysdir`, but doing so is irrelevant if you use the defaults.

`from(`*directory_or_url*`)`, when used with `net`, specifies the directory or URL where installable packages may be found. The directory or URL is the same as the one that would have been specified with `net from`.

Remarks

For an introduction to using `net` and `ado`, see [U] **28 Using the Internet to keep up to date**. The purpose of this documentation is

- to briefly, but accurately, describe `net` and `ado` and all their features and
- to provide documentation to those who wish to set up their own sites to distribute additions to Stata.

Remarks are presented under the following headings:

Definition of a package
The purpose of the net and ado commands
Content pages
Package-description pages
Where packages are installed
A summary of the net command
A summary of the ado command
Relationship of net and ado to the point-and-click interface
Creating your own site
Format of content and package-description files
Example 1
Example 2
Additional package directives
SMCL in content and package-description files
Error-free file delivery

Definition of a package

A *package* is a collection of files—typically, `.ado` and `.sthlp` files—that together provide a new feature in Stata. Packages contain additions that you wish had been part of Stata at the outset. We write such additions, and so do other users.

One source of these additions is the *Stata Journal*, a printed and electronic journal with corresponding software. If you want the journal, you must subscribe, but the software is available for free from our website.

The purpose of the net and ado commands

The net command makes it easy to distribute and install packages. The goal is to get you quickly to a package-description page that summarizes the addition, for example,

```
. net describe rte_stat, from(http://www.wemakeitupaswego.edu/faculty/sgazer/)
-------------------------------------------------------------------------------
package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer/
-------------------------------------------------------------------------------
TITLE
      rte_stat.  The robust-to-everything statistic; update.
DESCRIPTION/AUTHOR(S)
      S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.
      Aleph-0 100% confidence intervals proved too conservative for some
      applications; Aleph-1 confidence intervals have been substituted.
      The new robust-to-everything supplants the previous robust-to-
      everything-conceivable statistic.  See "Inference in the absence
      of data" (forthcoming).  After installation, see help rte.
INSTALLATION FILES                                  (type net install rte_stat)
      rte.ado
      rte.sthlp
      nullset.ado
      random.ado
-------------------------------------------------------------------------------
```

If you decide that the addition might prove useful, net makes the installation easy:

```
. net install rte_stat
checking rte_stat consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

The ado command helps you manage packages installed with net. Perhaps you remember that you installed a package that calculates the robust-to-everything statistic, but you cannot remember the command's name. You could use ado to search what you have previously installed for the rte command,

```
. ado
[1] package sg145 from http://www.stata.com/stb/stb56
      STB-56 sg145. Scalar measures of fit for regression models.
  (output omitted)
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
      rte_stat.  The robust-to-everything statistic; update.
  (output omitted)
[21] package st0119 from http://www.stata-journal.com/software/sj7-1
      SJ7-1 st0119.  Rasch analysis
```

or you might type

```
. ado, find("robust-to-everything")
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
      rte_stat.  The robust-to-everything statistic; update.
```

Perhaps you decide that rte, despite the author's claims, is not worth the disk space it occupies. You can use ado to erase it:

```
. ado uninstall rte_stat
package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
      rte_stat.  The robust-to-everything statistic; update.
(package uninstalled)
```

`ado uninstall` is easier than erasing the files by hand because `ado uninstall` erases every file associated with the package, and, moreover, `ado` knows where on your computer `rte_stat` is installed; you would have to hunt for these files.

Content pages

There are two types of pages displayed by `net`: content pages and package-description pages. When you type `net from`, `net cd`, `net link`, or `net` without arguments, Stata goes to the specified place and displays the content page:

```
. net from http://www.stata.com
------------------------------------------------------------------------------
http://www.stata.com/
StataCorp
------------------------------------------------------------------------------

Welcome to StataCorp.

Below we provide links to sites providing additions to Stata, including
the Stata Journal, STB, and Statalist.  These are NOT THE OFFICIAL UPDATES;
you fetch and install the official updates by typing -update-.

PLACES you could -net link- to:
    sj                The Stata Journal

DIRECTORIES you could -net cd- to:
    stb               materials published in the Stata Technical Bulletin
    users             materials written by various people, including StataCorp
                      employees
    meetings          software packages from Stata Users Group meetings
    links             links to other locations providing additions to Stata
------------------------------------------------------------------------------
```

A content page tells you about other content pages and package-description pages. The example above lists other content pages only. Below we follow one of the links for the *Stata Journal*:

```
. net link sj
------------------------------------------------------------------------------
http://www.stata-journal.com/
The Stata Journal
------------------------------------------------------------------------------

The Stata Journal is a refereed, quarterly journal containing articles
of interest to Stata users.  For more details and subscription information,
visit the Stata Journal website at http://www.stata-journal.com.

PLACES you could -net link- to:
    stata             StataCorp website

DIRECTORIES you could -net cd- to:

    stb               Stata Technical Bulletin (STB) software archive
DIRECTORIES you could -net cd- to:
  (output omitted)
    sj7-1             volume 7, issue 1
  (output omitted)
    sj1-1             volume 1, issue 1
-------------------------------------------------------------------------------

. net cd sj7-1
-------------------------------------------------------------------------------
http://www.stata-journal.com/software/sj7-1/
Stata Journal volume 7, issue 1
-------------------------------------------------------------------------------

DIRECTORIES you could -net cd- to:
    ..                Other Stata Journals
PACKAGES you could -net describe-:
    dm0027            File filtering in Stata: handling complex data
                      formats and navigating log files efficiently
    st0119            Rasch analysis
    st0120            Multivariable regression spline models
    st0121            mhbounds - Sensitivity Analysis for Average
                      Treatment Effects
-------------------------------------------------------------------------------
```

`dm0027`, `st0119`, ..., `st0121` are links to package-description pages.

1. When you type `net from`, you follow that with a location to display the location's content page.

   a. The location could be a URL, such as http://www.stata.com. The content page at that location would then be listed.

   b. The location could be `e:` on a Windows computer or a mounted volume on a Mac computer. The content page on that source would be listed. That would work if you had special media obtained from StataCorp or special media prepared by another user.

   c. The location could even be a directory on your computer, but that would work only if that directory contained the right kind of files.

2. Once you have specified a location, typing `net cd` will take you into subdirectories of that location, if there are any. Typing

   ```
   . net from http://www.stata-journal.com
   . net cd software
   ```

   is equivalent to typing

   ```
   . net from http://www.stata-journal.com/software
   ```

   Typing `net cd` displays the content page from that location.

3. Typing `net` without arguments redisplays the current content page, which is the content page last displayed.

4. `net link` is similar to `net cd` in that the result is to change the location, but rather than changing to subdirectories of the current location, `net link` jumps to another location:

```
. net from http://www.stata-journal.com
------------------------------------------------------------------------------
http://www.stata-journal.com/
The Stata Journal
------------------------------------------------------------------------------

The Stata Journal is a refereed, quarterly journal containing articles
of interest to Stata users.  For more details and subscription information,
visit the Stata Journal website at
http://www.stata-journal.com.

PLACES you could -net link- to:
    stata             StataCorp website

DIRECTORIES you could -net cd- to:
    production        Files for authors of the Stata Journal
    software          Software associated with Stata Journal articles
------------------------------------------------------------------------------
```

Typing `net link stata` would jump to http://www.stata.com:

```
. net link stata
------------------------------------------------------------------------------
http://www.stata.com/
StataCorp
------------------------------------------------------------------------------

Welcome to StataCorp.
  (output omitted)
------------------------------------------------------------------------------
```

Package-description pages

Package-description pages describe what could be installed:

```
. net from http://www.stata-journal.com/software/sj7-1
```

```
http://www.stata-journal.com/software/sj7-1/
  (output omitted)
. net describe st0119
```

```
package st0119 from http://www.stata-journal.com/software/sj7-1
```

```
TITLE
      SJ7-1 st0119.  Rasch analysis
DESCRIPTION/AUTHOR(S)
      Rasch analysis

      st0119/gausshermite.hlp
      st0119/geekel2d.ado
      st0119/geekel2d.hlp
ANCILLARY FILES                                   (type net get st0119)
      st0119/data.dta
      st0119/outrasch.do
```

A package-description page describes the package and tells you how to install the component files. Package-description pages potentially describe two types of files:

1. Installation files: files that you type `net install` to install and that are required to make the addition work.
2. Ancillary files: additional files that you might want to install—you type `net get` to install them—but that you can ignore. Ancillary files are typically datasets that are useful for demonstration purposes. Ancillary files are not really installed in the sense of being copied to an official place for use by Stata itself. They are merely copied into the current directory so that you may use them if you wish.

You install the official files by typing `net install` followed by the package name. For example, to install `st0119`, you would type

```
. net install st0119
checking st0119 consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

You get the ancillary files—if there are any and if you want them—by typing `net get` followed by the package name:

```
. net get st0119
checking st0119 consistency and verifying not already installed...
copying into current directory...
      copying  data.dta
      copying  outrasch.do
ancillary files successfully copied.
```

Most users ignore the ancillary files.

Once you have installed a package—by typing `net install`—use `ado` to redisplay the package-description page whenever you wish:

```
. ado describe st0119
```

```
[1] package st0119 from http://www.stata-journal.com/software/sj7-1
```

```

INSTALLED ON
      24 Apr 2011
```

The package-description page shown by `ado` includes the location from which we got the package and when we installed it. It does not mention the ancillary files that were originally part of this package because they are not tracked by `ado`.

Where packages are installed

Packages should be installed in `PLUS` or `SITE`, which are code words that Stata understands and that correspond to some real directories on your computer. Typing `sysdir` will tell you where these are, if you care.

```
. sysdir
   STATA:  C:\Program Files\Stata12\
 UPDATES:  C:\Program Files\Stata12\ado\updates\
    BASE:  C:\Program Files\Stata12\ado\base\
    SITE:  C:\Program Files\Stata12\ado\site\
    PLUS:  c:\ado\plus\
PERSONAL:  c:\ado\personal\
OLDPLACE:  c:\ado\
```

If you type `sysdir`, you may obtain different results.

By default, net installs in the PLUS directory, and ado tells you about what is installed there. If you are on a multiple-user system, you may wish to install some packages in the SITE directory. This way, they will be available to other Stata users. To do that, before using net install, type

```
. net set ado SITE
```

and when reviewing what is installed or removing packages, redirect ado to that directory:

```
. ado ..., from(SITE)
```

In both cases, you type SITE because Stata will understand that SITE means the site ado-directory as defined by sysdir. To install into SITE, you must have write access to that directory.

If you reset where net installs and then, in the same session, wish to install into your private ado-directory, type

```
. net set ado PLUS
```

That is how things were originally. If you are confused as to where you are, type net query.

A summary of the net command

The net command displays content pages and package-description pages. Such pages are provided over the Internet, and most users get them there. We recommend that you start at http://www.stata.com and work out from there. We also recommend using net search to find packages of interest to you; see [R] **net search**.

net from moves you to a location and displays the content page.

net cd and net link change from your current location to other locations. net cd enters subdirectories of the original location. net link jumps from one location to another, depending on the code on the content page.

net describe lists a package-description page. Packages are named, and you type net describe *pkgname*.

net install installs a package into your copy of Stata. net get copies any additional files (ancillary files) to your current directory.

net sj and net stb simplify loading files from the *Stata Journal* and its predecessor, the *Stata Technical Bulletin*.

net sj *vol-issue*

is a synonym for typing

net from http://www.stata-journal.com/software/sj*vol-issue*

whereas

net sj *vol-issue insert*

is a synonym for typing

net from http://www.stata-journal.com/software/sj*vol-issue*
net describe *insert*

net set controls where net installs files. By default, net installs in the PLUS directory; see [P] **sysdir**. net set ado SITE would cause subsequent net commands to install in the SITE directory. net set other sets where ancillary files, such as .dta files, are installed. The default is the current directory.

net query displays the current net from, net set ado, and net set other settings.

A summary of the ado command

The ado command lists the package descriptions of previously installed packages.

Typing ado without arguments is the same as typing ado dir. Both list the names and titles of the packages you have installed.

ado describe lists full package-description pages.

ado uninstall removes packages from your computer.

Because you can install packages from a variety of sources, the package names may not always be unique. Thus the packages installed on your computer are numbered sequentially, and you may refer to them by name or by number. For instance, say that you wanted to get rid of the robust-to-everything statistic command you installed. Type

```
. ado, find("robust-to-everything")
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
     rte_stat.  The robust-to-everything statistic; update.
```

You could then type

```
. ado uninstall rte_stat
```

or

```
. ado uninstall [15]
```

Typing ado uninstall rte_stat would work only if the name rte_stat were unique; otherwise, ado would refuse, and you would have to type the number.

The find() option is allowed with ado dir and ado describe. It searches the package description for the word or phrase you specify, ignoring case (alpha matches Alpha). The complete package description is searched, including the author's name and the name of the files. Thus if rte was the name of a command that you wanted to eliminate, but you could not remember the name of the package, you could type

```
. ado, find(rte)
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
     rte_stat.  The robust-to-everything statistic; update.
```

Relationship of net and ado to the point-and-click interface

Users may instead select **Help > SJ and User-written Programs**. There are advantages and disadvantages:

1. Flipping through content and package-description pages is easier; it is much like a browser. See [GS] **19 Updating and extending Stata—Internet functionality** (GSM, GSU, or GSW).
2. When browsing a product-description page, note that the .sthlp files are highlighted. You may click on .sthlp files to review them before installing the package.
3. You may not redirect from where ado searches for files.

Creating your own site

The rest of this entry concerns how to create your own site to distribute additions to Stata. The idea is that you have written additions for use with Stata—say, `xyz.ado` and `xyz.sthlp`—and you wish to put them out so that coworkers or researchers at other institutions can easily install them. Or, perhaps you just have a dataset that you and others want to share.

In any case, all you need is a webpage. You place the files that you want to distribute on your webpage (or in a subdirectory), and you add two more files—a content file and a package-description file—and you are done.

Format of content and package-description files

The content file describes the content page. It must be named `stata.toc`:

begin `stata.toc`

```
OFF                                          (to make site unavailable temporarily)
* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files
v 3
* d lines display description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d text
d
...
* l lines display links
l word-to-show path-or-url [description]
l word-to-show path-or-url [description]
...
* t lines display other directories within the site
t path [description]
t path [description]
...
* p lines display packages
p pkgname [description]
p pkgname [description]
...
```

end `stata.toc`

Package files describe packages and are named *pkgname*`.pkg`:

begin *pkgname*.pkg

```
* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files
v 3
* d lines display package description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d Distribution-Date: date
d text
d
...
* f identifies the component files
f [path/]filename [description]
f [path/]filename [description]
...
* e line is optional; it means stop reading
e
```

end *pkgname*.pkg

Note the Distribution-Date description line. This line is optional but recommended. Stata can look for updates to user-written programs with the `adoupdate` command if the package files from which those programs were installed contain a Distribution-Date description line.

Example 1

Say that we want the user to see the following:

```
. net from http://www.university.edu/~me
------------------------------------------------------------------------------
http://www.university.edu/~me
Chris Farrar, Uni University
------------------------------------------------------------------------------

PACKAGES you could -net describe-:
    xyz              interval-truncated survival

. net describe xyz
------------------------------------------------------------------------------
package xyz from http://www.university.edu/~me
------------------------------------------------------------------------------

TITLE
      xyz.  interval-truncated survival.
DESCRIPTION/AUTHOR(S)
      C. Farrar, Uni University.
INSTALLATION FILES                                (type net install xyz)
      xyz.ado
      xyz.sthlp
ANCILLARY FILES                                   (type net get xyz)
      sample.dta
------------------------------------------------------------------------------
```

The files needed to do this would be

begin stata.toc

```
v 3
d Chris Farrar, Uni University
p xyz interval-truncated survival
```

end stata.toc

begin xyz.pkg
```
v 3
d xyz.  interval-truncated survival.
d C. Farrar, Uni University.
f xyz.ado
f xyz.sthlp
f sample.dta
```
end xyz.pkg

On his homepage, Chris would place the following files:

stata.toc	(shown above)
xyz.pkg	(shown above)
xyz.ado	file to be delivered (for use by net install)
xyz.sthlp	file to be delivered (for use by net install)
sample.dta	file to be delivered (for use by net get)

Chris does nothing to distinguish ancillary files from installation files.

Example 2

S. Gazer wants to create a more complex site:

```
. net from http://www.wemakeitupaswego.edu/faculty/sgazer
------------------------------------------------------------------------------
http://www.wemakeitupaswego.edu/faculty/sgazer
Data-free inference materials
------------------------------------------------------------------------------

S. Gazer, Department of Applied Theoretical Mathematics

Also see my homepage for the preprint of "Irrefutable inference".

PLACES you could -net link- to:
    stata             StataCorp website

DIRECTORIES you could -net cd- to:
    ir               irrefutable inference programs (work in progress)

PACKAGES you could -net describe-:
    rtec             Robust-to-everything-conceivable statistic
    rte              Robust-to-everything statistic
```

```
. net describe rte
------------------------------------------------------------------------------
package rte from http://www.wemakeitupaswego.edu/faculty/sgazer/
------------------------------------------------------------------------------

TITLE
      rte.  The robust-to-everything statistic; update.

DESCRIPTION/AUTHOR(S)
      S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.
      Aleph-0 100% confidence intervals proved too conservative for some
      applications; Aleph-1 confidence intervals have been substituted.
      The new robust-to-everything supplants the previous robust-to-
      everything-conceivable statistic.  See "Inference in the absence
      of data" (forthcoming).  After installation, see help rte.

      Distribution-Date: 20110420

      Support:  email sgazer@wemakeitupaswego.edu

f rte.ado
f rte.sthlp
f nullset.ado
f random.ado
f empty.dta
------------------------------------------------------------ end rte.pkg -
```

On his homepage, Mr. Gazer would place the following files:

`stata.toc`	(shown above)
`rte.pkg`	(shown above)
`rte.ado`	(file to be delivered)
`rte.sthlp`	(file to be delivered)
`nullset.ado`	(file to be delivered)
`random.ado`	(file to be delivered)
`empty.dta`	(file to be delivered)
`rtec.pkg`	the other package referred to in `stata.toc`
`rtec.ado`	the corresponding files to be delivered
`rtec.sthlp`	
`ir/stata.toc`	the contents file for when the user types `net cd ir`
`ir/...`	whatever other `.pkg` files are referred to
`ir/...`	whatever other files are to be delivered

If Mr. Gazer later updated the `rte` package, he could change the Distribution-Date description line in his package. Then, if someone who had previously installed the `rte` packaged wanted to obtain the latest version, that person could use the `adoupdate` command; see [R] **adoupdate**.

For complex sites, a different structure may prove more convenient:

`stata.toc`	(shown above)
`rte.pkg`	(shown above)
`rtec.pkg`	the other package referred to in `stata.toc`
`rte/`	directory containing rte files to be delivered:
`rte/rte.ado`	(file to be delivered)
`rte/rte.sthlp`	(file to be delivered)
`rte/nullset.ado`	(file to be delivered)
`rte/random.ado`	(file to be delivered)
`rte/empty.dta`	(file to be delivered)
`rtec/`	directory containing rtec files to be delivered:
`rtec/...`	(files to be delivered)
`ir/stata.toc`	the contents file for when the user types `net cd ir`
`ir/*.pkg`	whatever other package files are referred to
`ir/*/...`	whatever other files are to be delivered

If you prefer this structure, it is simply a matter of changing the bottom of the `rte.pkg` from

```
f rte.ado
f rte.sthlp
f nullset.ado
f random.ado
f empty.dta
```

to

```
f rte/rte.ado
f rte/rte.sthlp
f rte/nullset.ado
f rte/random.ado
f rte/empty.dta
```

In writing paths and files, the directory separator forward slash (`/`) is used, regardless of operating system, because this is what the Internet uses.

It does not matter whether the files you put out are in Windows, Mac, or Unix format (how lines end is recorded differently). When Stata reads the files over the Internet, it will figure out the file format on its own and will automatically translate the files to what is appropriate for the receiver.

Additional package directives

F *filename* is similar to f *filename*, except that, when the file is installed, it will always be copied to the system directories (and not the current directory).

With f *filename*, the file is installed into a directory according to the file's suffix. For instance, xyz.ado would be installed in the system directories, whereas xyz.dta would be installed in the current directory.

Coding F xyz.ado would have the same result as coding f xyz.ado.

Coding F xyz.dta, however, would state that xyz.dta is to be installed in the system directories.

g *platformname filename* is also a variation on f *filename*. It specifies that the file be installed only if the user's operating system is of type *platformname*; otherwise, the file is ignored. The platform names are WIN (32-bit x86) and WIN64A (64-bit x86-64) for Windows; MACINTEL (32-bit Intel, GUI), OSX.X86 (32-bit Intel, console), MACINTEL64 (64-bit Intel, GUI), OSX.X8664 (64-bit Intel, console), MAC (32-bit PowerPC), and OSX.PPC (32-bit PowerPC), for Mac; and LINUX (32-bit x86), LINUX64 (64-bit x86-64), SOL64, and SOLX8664 (64-bit x86-64) for Unix.

G *platformname filename* is a variation on F *filename*. The file, if not ignored, is to be installed in the system directories.

g *platformname filename1 filename2* is a more detailed version of g *platformname filename*. In this case, *filename1* is the name of the file on the server (the file to be copied), and *filename2* is to be the name of the file on the user's system; for example, you might code

```
g WIN mydll.forwin mydll.plugin
g LINUX mydll.forlinux mydll.plugin
```

When you specify one *filename*, the result is the same as specifying two identical *filename*s.

G *platformname filename1 filename2* is the install-in-system-directories version of g *platformname filename1 filename2*.

h *filename* asserts that *filename* must be loaded, or this package is not to be installed; for example, you might code

```
g WIN mydll.forwin mydll.plugin
g LINUX mydll.forlinux mydll.plugin
h mydll.plugin
```

if you were offering the plugin mydll.plugin for Windows and Linux only.

SMCL in content and package-description files

The text listed on the second and subsequent d lines in both stata.toc and *pkgname*.pkg may contain SMCL as long as you include v 3; see [P] **smcl**.

Thus, in rte.pkg, S. Gazer coded the third line as

```
d {bf:S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.}
```

Error-free file delivery

Most people transport files over the Internet and never worry about the file being corrupted in the process because corruption rarely occurs. If, however, the files must be delivered perfectly or not at all, you can include checksum files in the directory.

For instance, say that `big.dta` is included in your package and that it must be sent perfectly. First, use Stata to make the checksum file for `big.dta`

```
. checksum big.dta, save
```

That command creates a small file called `big.sum`; see [D] **checksum**. Then copy both `big.dta` and `big.sum` to your homepage. If `set checksum` is `on` (the default is `off`), whenever Stata reads *filename*`.`*whatever* over the net, it also looks for *filename*`.sum`. If it finds such a file, it uses the information recorded in it to verify that what was copied was error free.

If you do this, be cautious. If you put `big.dta` and `big.sum` on your homepage and then later change `big.dta` without changing `big.sum`, people will think that there are transmission errors when they try to download `big.dta`.

Title

net search — Search the Internet for installable packages

Syntax

`net search` *word* [*word* ...] [, *options*]

options	Description
`or`	list packages that contain any of the keywords; default is all
`nosj`	search non-SJ and non-STB sources
`tocpkg`	search both tables of contents and packages; the default
`toc`	search tables of contents only
`pkg`	search packages only
`everywhere`	search packages for match
`filenames`	search filenames associated with package for match
`errnone`	make return code 111 instead of 0 when no matches found

Description

`net search` searches the Internet for user-written additions to Stata, including, but not limited to, user-written additions published in the *Stata Journal* (SJ) and in the *Stata Technical Bulletin* (STB). `net search` lists the available additions that contain the specified keywords.

The user-written materials found are available for immediate download by using the `net` command or by clicking on the link.

In addition to typing `net search`, you may select **Help > Search...** and choose **Search net resources**. This is the recommended way to search for user-written additions to Stata.

Options

`or` is relevant only when multiple keywords are specified. By default, `net search` lists only packages that include all the keywords. `or` changes the command to list packages that contain any of the keywords.

`nosj` specifies that `net search` not list matches that were published in the SJ or in the STB.

`tocpkg`, `toc`, and `pkg` determine what is searched. `tocpkg` is the default, meaning that both tables of contents (tocs) and packages (pkgs) are searched. `toc` restricts the search to tables of contents. `pkg` restricts the search to packages.

`everywhere` and `filenames` determine where in packages `net search` looks for *keywords*. The default is `everywhere`. `filenames` restricts `net search` to search for matches only in the filenames associated with a package. Specifying `everywhere` implies `pkg`.

`errnone` is a programmer's option that causes the return code to be 111 instead of 0 when no matches are found.

Remarks

`net search` searches the Internet for user-written additions to Stata. If you want to search the Stata documentation for a particular topic, command, or author, see [R] **search**. `net search` *word* [*word* ...] (without options) is equivalent to typing `search` *word* [*word* ...]`, net`.

Remarks are presented under the following headings:

Topic searches
Author searches
Command searches
Where does net search look?
How does net search work?

Topic searches

Example: Find what is available about random effects

```
. net search random effect
```

Comments:

- It is best to search using the singular form of a word. `net search random effect` will find both "random effect" and "random effects".
- `net search random effect` will also find "random-effect" because `net search` performs a string search and not a word search.
- `net search random effect` lists all packages containing the words "random" and "effect", not necessarily used together.
- If you wanted all packages containing the word "random" or the word "effect", you would type `net search random effect, or`.

Author searches

Example: Find what is available by author Jeroen Weesie

```
. net search weesie
```

Comments:

- You could type `net search jeroen weesie`, but that might list fewer results because sometimes the last name is used without the first.
- You could type `net search Weesie`, but it would not matter. Capitalization is ignored in the search.

Example: Find what is available by Jeroen Weesie, excluding SJ and STB materials

```
. net search weesie, nosj
```

- The SJ and the STB tend to dominate search results because so much has been published in them. If you know that what you are looking for is not in the SJ or in the STB, specifying the `nosj` option will narrow the search.
- `net search weesie` lists everything that `net search weesie, nosj` lists, and more. If you just type `net search weesie`, look down the list. SJ and STB materials are listed first, and non-SJ and non-STB materials are listed last.

Command searches

Example: Find the user-written command kursus

```
. net search kursus, file
```

- You could just type `net search kursus`, and that will list everything `net search kursus, file` lists, and more. Because you know `kursus` is a command, however, there must be a `kursus.ado` file associated with the package. Typing `net search kursus, file` narrows the search.
- You could also type `net search kursus.ado, file` to narrow the search even more.

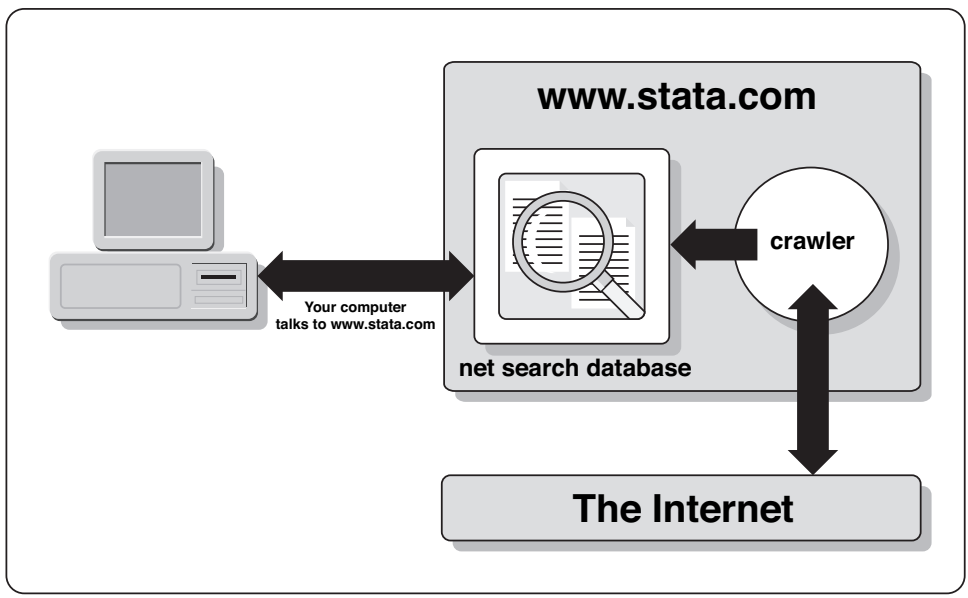
Where does net search look?

`net search` looks everywhere, not just at http://www.stata.com.

`net search` begins by looking at http://www.stata.com, but then follows every link, which takes it to other places, and then follows every link again, which takes it to even more places, and so on.

Authors: Please let us know if you have a site that we should include in our search by sending an email to webmaster@stata.com. We will then link to your site from ours to ensure that `net search` finds your materials. That is not strictly necessary, however, as long as your site is directly or indirectly linked from some site that is linked to ours.

How does net search work?



Our website maintains a database of Stata resources. When you use `net search`, it contacts http://www.stata.com with your request, http://www.stata.com searches its database, and Stata returns the results to you.

Another part of the system is called the crawler, which searches the web for new Stata resources to add to the `net search` database and verifies that the resources already found are still available. When a new resource becomes available, the crawler takes about 2 days to add it to the database, and, similarly, if a resource disappears, the crawler takes roughly 2 days to remove it from the database.

set timeout1 #seconds [, permanently]
```

Set time limit for data transfer

```
set timeout2 #seconds [, permanently]
```

Description

Several commands (for example, `net`, `news`, and `update`) are designed specifically for use over the Internet. Many other Stata commands that read a file (for example, `copy`, `type`, and `use`) can also read directly from a URL. All these commands will usually work without your ever needing to concern yourself with the `set` commands discussed here. These `set` commands provide control over network system parameters.

If you experience problems when using Stata's network features, ask your system administrator if your site uses a proxy. A proxy is a server between your computer and the rest of the Internet, and your computer may need to communicate with other computers on the Internet through this proxy. If your site uses a proxy, your system administrator can provide you with its host name and the port your computer can use to communicate with it. If your site's proxy requires you to log in to it before it will respond, your system administrator will provide you with a user ID and password.

`set httpproxyhost` sets the name of the host to be used as a proxy server. `set httpproxyport` sets the port number. `set httpproxy` turns on or off the use of a proxy server, leaving the proxy host name and port intact, even when not in use.

Under the Mac and Windows operating systems, when you `set httpproxy on`, Stata will attempt to obtain the values of `httpproxyhost` and `httpproxyport` from the operating system if they have not been previously set. `set httpproxy on, init` attempts to obtain these values from the operating system, even if they have been previously set.

If the proxy requires authorization (user ID and password), set authorization on via `set httpproxyauth on`. The proxy user and proxy password must also be set to the appropriate user ID and password by using `set httpproxyuser` and `set httpproxypw`.

Stata remembers the various proxy settings between sessions and does not need a `permanently` option.

`set timeout1` changes the time limit in seconds that Stata imposes for establishing the initial connection with a remote host. The default value is 30. `set timeout2` changes the time limit in seconds that Stata imposes for subsequent data transfer with the host. The default value is 180. If these time limits are exceeded, a "connection timed out" message and error code 2 are produced. You should seldom need to change these settings.

Options

`init` specifies that `set httpproxy on` attempts to initialize `httpproxyhost` and `httpproxyport` from the operating system (Mac and Windows only).

`permanently` specifies that, in addition to making the change right now, the `timeout1` and `timeout2` settings be remembered and become the default setting when you invoke Stata.

The various `httpproxy` settings do not have a `permanently` option because `permanently` is implied.

Remarks

If you receive an error message, see http://www.stata.com/support/faqs/web/ for the latest information.

1. remote connection failed r(677);

If you see

```
remote connection failed
r(677);
```

then you asked for something to be done over the web, and Stata tried but could not contact the specified host. Stata was able to talk over the network and look up the host but was not able to establish a connection to that host. Perhaps the host is down; try again later.

If all your web accesses result in this message, then perhaps your network connection is through a proxy server. If it is, then you must tell Stata.

Contact your system administrator. Ask for the name and port of the "HTTP proxy server". Say that you are told

> HTTP proxy server: jupiter.myuni.edu
> port number: 8080

In Stata, type

```
. set httpproxyhost jupiter.myuni.edu
. set httpproxyport 8080
. set httpproxy on
```

Your web accesses should then work.

2. connection timed out r(2);

If you see

```
connection timed out
r(2);
```

then an Internet connection has timed out. This can happen when

a. the connection between you and the host is slow, or

b. the connection between you and the host has disappeared, and so it eventually "timed out".

For (b), wait a while (say, 5 minutes) and try again (sometimes pieces of the Internet can break for up to a day, but that is rare). For (a), you can reset the limits for what constitutes "timed out". There are two numbers to set.

The time to establish the initial connection is **timeout1**. By default, Stata waits 30 seconds before declaring a timeout. You can change the limit:

```
. set timeout1 #seconds
```

You might try doubling the usual limit and specify 60; *#seconds* must be between 1 and 32,000.

The time to retrieve data from an open connection is **timeout2**. By default, Stata waits 180 seconds (3 minutes) before declaring a timeout. To change the limit, type

```
. set timeout2 #seconds
```

You might try doubling the usual limit and specify 360; *#seconds* must be between 1 and 32,000.

Title

nl — Nonlinear least-squares estimation

Syntax

Interactive version

```
nl (depvar = <sexp>) [if] [in] [weight] [, options]
```

Programmed substitutable expression version

```
nl sexp_prog : depvar [varlist] [if] [in] [weight] [, options]
```

Function evaluator program version

```
nl func_prog @ depvar [varlist] [if] [in] [weight] ,
    { parameters(namelist) | nparameters(#) } [options]
```

where

depvar is the dependent variable;

<sexp> is a substitutable expression;

sexp_prog is a substitutable expression program; and

func_prog is a function evaluator program.

options	Description
Model	
`variables(`*varlist*`)`	variables in model
`initial(`*initial_values*`)`	initial values for parameters
* `parameters(`*namelist*`)`	parameters in model (function evaluator program version only)
* `nparameters(#)`	number of parameters in model (function evaluator program version only)
sexp_options	options for substitutable expression program
func_options	options for function evaluator program
Model 2	
`lnlsq(#)`	use log least-squares where $\ln(depvar - \#)$ is assumed to be normally distributed
`noconstant`	the model has no constant term; seldom used
`hasconstant(`*name*`)`	use *name* as constant term; seldom used
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `gnr`, `robust`, `cluster` *clustvar*, `bootstrap`, `jacknife`, `hac` *kernel*, `hc2`, or `hc3`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`leave`	create variables containing derivative of $E(y)$
`title(`*string*`)`	display *string* as title above the table of parameter estimates
`title2(`*string*`)`	display *string* as subtitle
display_options	control column formats and line width
Optimization	
optimization_options	control the optimization process; seldom used
`eps(#)`	specify # for convergence criterion; default is `eps(1e-5)`
`delta(#)`	specify # for computing derivatives; default is `delta(4e-7)`
`coeflegend`	display legend instead of statistics

* For function evaluator program version, you must specify `parameters(`*namelist*`)` or `nparameters(#)`, or both.
`bootstrap`, `by`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.
`vce()`, `leave`, and weights are not allowed with the `svy` prefix; see [SVY] **svy**.
`aweights`, `fweights`, and `iweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Statistics > Linear models and related > Nonlinear least squares

Description

nl fits an arbitrary nonlinear regression function by least squares. With the interactive version of the command, you enter the function directly on the command line or in the dialog box by using a *substitutable expression*. If you have a function that you use regularly, you can write a *substitutable expression program* and use the second syntax to avoid having to reenter the function every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the regression function.

When you write a substitutable expression program or function evaluator program, the first two letters of the name must be nl. *sexp_prog* and *func_prog* refer to the name of the program without the first two letters. For example, if you wrote a function evaluator program named nlregss, you would type nl regss @ ... to estimate the parameters.

Options

Model

variables(*varlist*) specifies the variables in the model. nl ignores observations for which any of these variables have missing values. If you do not specify variables(), then nl issues an error message with return code 480 if the estimation sample contains any missing values.

initial(*initial_values*) specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where k is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize alpha to 1.23 and delta to 4.57, you would type

```
nl ... , initial(alpha 1.23 delta 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, nl exits with error code 480. If you specify a matrix, the values must be in the same order that the parameters are declared in your model. nl ignores the row and column names of the matrix.

parameters(*namelist*) specifies the names of the parameters in the model. The names of the parameters must adhere to the naming conventions of Stata's variables; see [U] **11.3 Naming conventions**. If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter; if not, nl issues an error message with return code 198.

nparameters(#) specifies the number of parameters in the model. If you do not specify names with the parameters() option, nl names them b1, b2, ..., b#. If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter; if not, nl issues an error message with return code 198.

sexp_options refer to any options allowed by your *sexp_prog*.

func_options refer to any options allowed by your *func_prog*.

Model 2

lnlsq(#) fits the model by using log least-squares, which we define as least squares with shifted lognormal errors. In other words, $\ln(depvar - \#)$ is assumed to be normally distributed. Sums of squares and deviance are adjusted to the same scale as *depvar*.

`noconstant` indicates that the function does not include a constant term. This option is generally not needed, even if there is no constant term in the model, unless the coefficient of variation (over observations) of the partial derivative of the function with respect to a parameter is less than `eps()` and that parameter is not a constant term.

`hasconstant(`*name*`)` indicates that parameter *name* be treated as the constant term in the model and that `nl` should not use its default algorithm to find a constant term. As with `noconstant`, this option is seldom used.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(gnr)`, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

`nl` also allows the following:

`vce(hac` *kernel* `[`*#*`])` specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels available for `nl`:

`nwest` | `gallant` | `anderson`

specifies the number of lags. If *#* is not specified, $N-2$ is assumed.

`vce(hac` *kernel* `[`*#*`])` is not allowed if weights are specified.

`vce(hc2)` and `vce(hc3)` specify alternative bias corrections for the robust variance calculation. `vce(hc2)` and `vce(hc3)` may not be specified with the `svy` prefix. By default, `vce(robust)` uses $\widehat{\sigma}_j^2 = \{n/(n-k)\}u_j^2$ as an estimate of the variance of the jth observation, where u_j is the calculated residual and $n/(n-k)$ is included to improve the overall estimate's small-sample properties.

`vce(hc2)` instead uses $u_j^2/(1-h_{jj})$ as the observation's variance estimate, where h_{jj} is the jth diagonal element of the hat (projection) matrix. This produces an unbiased estimate of the covariance matrix if the model is homoskedastic. `vce(hc2)` tends to produce slightly more conservative confidence intervals than `vce(robust)`.

`vce(hc3)` uses $u_j^2/(1-h_{jj})^2$ as suggested by Davidson and MacKinnon (1993 and 2004), who report that this often produces better results when the model is heteroskedastic. `vce(hc3)` produces confidence intervals that tend to be even more conservative.

See, in particular, Davidson and MacKinnon (2004, 239), who advocate the use of `vce(hc2)` or `vce(hc3)` instead of the plain robust estimator for nonlinear least squares.

Reporting

`level(#)`; see [R] **estimation options**.

`leave` leaves behind after estimation a set of new variables with the same names as the estimated parameters containing the derivatives of $E(y)$ with respect to the parameters. If the dataset contains an existing variable with the same name as a parameter, then using `leave` causes `nl` to issue an error message with return code 110.

`leave` may not be specified with `vce(cluster` *clustvar*`)` or the `svy` prefix.

`title(`*string*`)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(`*string*`)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

display_options: `cformat(`%*fmt*`)`, `pformat(`%*fmt*`)`, `sformat(`%*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Optimization

optimization_options: `iterate(#)`, [`no`]`log`, `trace`. `iterate()` specifies the maximum number of iterations, `log`/`nolog` specifies whether to show the iteration log, and `trace` specifies that the iteration log should include the current parameter vector. These options are seldom used.

`eps(#)` specifies the convergence criterion for successive parameter estimates and for the residual sum of squares. The default is `eps(1e-5)`.

`delta(#)` specifies the relative change in a parameter to be used in computing the numeric derivatives. The derivative for parameter β_i is computed as $\{f(X,\beta_1,\beta_2,\ldots,\beta_i+d,\beta_{i+1},\ldots) - f(X,\beta_1,\beta_2,\ldots,\beta_i,\beta_{i+1},\ldots)\}/d$, where d is $\delta(\beta_i+\delta)$. The default is `delta(4e-7)`.

The following options are available with `nl` but are not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Function evaluator programs

`nl` fits an arbitrary nonlinear function by least squares. The interactive version allows you to enter the function directly on the command line or dialog box using *substitutable expressions*. You can write a *substitutable expression program* for functions that you fit frequently to save yourself time. Finally, *function evaluator programs* give you the most flexibility in defining your nonlinear function, though they are more complicated to use.

The next section explains the substitutable expressions that are used to define the regression function, and the section thereafter explains how to write substitutable expression program files so that you do not need to type in commonly used functions over and over. Later sections highlight other features of `nl`.

The final section discusses function evaluator programs. If you find substitutable expressions adequate to define your nonlinear function, then you can skip that section entirely. Function evaluator programs are generally needed only for complicated problems, such as multistep estimators. The program receives a vector of parameters at which it is to compute the function and a variable into which the results are to be placed.

Substitutable expressions

You define the nonlinear function to be fit by `nl` by using a substitutable expression. Substitutable expressions are just like any other mathematical expressions involving scalars and variables, such as those you would use with Stata's `generate` command, except that the parameters to be estimated are bound in braces. See [U] **13.2 Operators** and [U] **13.3 Functions** for more information on expressions.

For example, suppose that you wish to fit the function

$$y_i = \beta_0(1 - e^{-\beta_1 x_i}) + \epsilon_i$$

where β_0 and β_1 are the parameters to be estimated and ϵ_i is an error term. You would simply type

```
. nl (y = {b0}*(1 - exp(-1*{b1}*x)))
```

You must enclose the entire equation in parentheses. Because `b0` and `b1` are enclosed in braces, `nl` knows that they are parameters in the model. `nl` will initialize `b0` and `b1` to zero by default. To request that `nl` initialize `b0` to 1 and `b1` to 0.25, you would type

```
. nl (y = {b0=1}*(1 - exp(-1*{b1=0.25}*x)))
```

That is, inside the braces denoting a parameter, you put the parameter name followed by an equal sign and the initial value. If a parameter appears in your function multiple times, you need only specify an initial value only once (or never, if you wish to set the initial value to zero). If you do specify more than one initial value for the same parameter, `nl` will use the *last* value given. Parameter names must follow the same conventions as variable names. See [U] **11.3 Naming conventions**.

Frequently, even nonlinear functions contain linear combinations of variables. As an example, suppose that you wish to fit the function

$$y_i = \beta_0 \left\{1 - e^{-(\beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i})}\right\} + \epsilon_i$$

`nl` allows you to declare a linear combination of variables by using the shorthand notation

```
. nl (y = {b0=1}*(1 - exp(-1*{xb: x1 x2 x3})))
```

In the syntax `{xb: x1 x2 x3}`, you are telling `nl` that you are declaring a linear combination named `xb` that is a function of three variables, `x1`, `x2`, and `x3`. `nl` will create three parameters, named `xb_x1`, `xb_x2`, and `xb_x3`, and initialize them to zero. Instead of typing the previous command, you could have typed

```
. nl (y = {b0=1}*(1 - exp(-1*({xb_x1}*x1 + {xb_x2}*x2 + {xb_x3}*x3))))
```

and yielded the same result. You can refer to the parameters created by `nl` in the linear combination later in the function, though you must declare the linear combination first if you intend to do that. When creating linear combinations, `nl` ensures that the parameter names it chooses are unique and have not yet been used in the function.

In general, there are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in braces: `{b0}`, `{param}`, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: `{b0=1}`, `{param=3.571}`, etc.
3. Linear combinations of variables can be included using the notation {*eqname*`:`*varlist*}, for example, `{xb: mpg price weight}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

If you specify initial values by using the `initial()` option, they override whatever initial values are given within the substitutable expression. Substitutable expressions are so named because, once values are assigned to the parameters, the resulting expression can be handled by `generate` and `replace`.

▷ Example 1

We wish to fit the CES production function

$$\ln Q_i = \beta_0 - \frac{1}{\rho}\ln\left\{\delta K_i^{-\rho} + (1-\delta)L_i^{-\rho}\right\} + \epsilon_i \tag{1}$$

where $\ln Q_i$ is the log of output for firm i; K_i and L_i are firm i's capital and labor usage, respectively; and ϵ_i is a regression error term. Because ρ appears in the denominator of a fraction, zero is not a feasible initial value; for a CES production function, $\rho = 1$ is a reasonable choice. Setting $\delta = 0.5$ implies that labor and capital have equal impacts on output, which is also a reasonable choice for an initial value. We type

```
. use http://www.stata-press.com/data/r12/production
. nl (lnoutput = {b0} - 1/{rho=1}*ln({delta=0.5}*capital^(-1*{rho}) +
> (1 - {delta})*labor^(-1*{rho})))
(obs = 100)
Iteration 0:  residual SS =  29.38631
Iteration 1:  residual SS =  29.36637
Iteration 2:  residual SS =  29.36583
Iteration 3:  residual SS =  29.36581
Iteration 4:  residual SS =  29.36581
Iteration 5:  residual SS =  29.36581
Iteration 6:  residual SS =  29.36581
Iteration 7:  residual SS =  29.36581
```

Source	SS	df	MS		
Model	91.1449924	2	45.5724962	Number of obs	100
Residual	29.3658055	97	.302740263	R-squared	0.7563
				Adj R-squared	0.7513
Total	120.510798	99	1.21728079	Root MSE	.5502184
				Res. dev.	161.2538

lnoutput	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
/b0	3.792158	.099682	38.04	0.000	3.594316	3.989999
/rho	1.386993	.472584	2.93	0.004	.4490443	2.324941
/delta	.4823616	.0519791	9.28	0.000	.3791975	.5855258

```
  Parameter b0 taken as constant term in model & ANOVA table
```

`nl` will attempt to find a constant term in the model and, if one is found, mention it at the bottom of the output. `nl` found `b0` to be a constant because the partial derivative $\partial \ln Q_i/\partial$`b0` has a coefficient of variation less than `eps()` in the estimation sample.

The elasticity of substitution for the CES production function is $\sigma = 1/(1+\rho)$; and, having fit the model, we can use `nlcom` to estimate it:

```
. nlcom (1/(1 + _b[/rho]))
       _nl_1:  1/(1 + _b[/rho])
```

lnoutput	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
_nl_1	.4189372	.0829424	5.05	0.000	.2543194	.583555

See [R] **nlcom** and [U] **13.5 Accessing coefficients and standard errors** for more information.

◁

`nl`'s output closely mimics that of `regress`; see [R] **regress** for more information. The R^2, sums of squares, and similar statistics are calculated in the same way that `regress` calculates them. If no "constant" term is specified, the usual caveats apply to the interpretation of the R^2 statistic; see the comments and references in Goldstein (1992). Unlike `regress`, `nl` does not report a model F statistic, because a test of the joint significance of all the parameters except the constant term may not be relevant in a nonlinear model.

Substitutable expression programs

If you fit the same model often or if you want to write an estimator that will operate on whatever variables you specify, then you will want to write a substitutable expression program. That program will return a macro containing a substitutable expression that `nl` can then evaluate, and it may optionally calculate initial values as well. The name of the program must begin with the letters `nl`.

To illustrate, suppose that you use the CES production function often in your work. Instead of typing in the formula each time, you can write a program like this:

```
program nlces, rclass
        version 12
        syntax varlist(min=3 max=3) [if]
        local logout : word 1 of `varlist'
        local capital : word 2 of `varlist'
        local labor : word 3 of `varlist'
        // Initial value for b0 given delta=0.5 and rho=1
        tempvar y
        generate double `y' = `logout' + ln(0.5*`capital'^-1 + 0.5*`labor'^-1)
        summarize `y' `if', meanonly
        local b0val = r(mean)
        // Terms for substitutable expression
        local capterm "{delta=0.5}*`capital'^(-1*{rho})"
        local labterm "(1-{delta})*`labor'^(-1*{rho})"
        local term2   "1/{rho=1}*ln(`capterm' + `labterm')"
        // Return substitutable expression and title
        return local eq "`logout' = {b0=`b0val'} - `term2'"
        return local title "CES ftn., ln Q=`logout', K=`capital', L=`labor'"
end
```

The program accepts three variables for log output, capital, and labor, and it accepts an `if` *exp* qualifier to restrict the estimation sample. All programs that you write to use with `nl` must accept an `if` *exp* qualifier because, when `nl` calls the program, it passes a binary variable that marks the estimation sample (the variable equals one if the observation is in the sample and zero otherwise). When calculating initial values, you will want to restrict your computations to the estimation sample, and you can do so by using `if` with any commands that accept `if` *exp* qualifiers. Even if your program does not calculate initial values or otherwise use the `if` qualifier, the `syntax` statement must still allow it. See [P] **syntax** for more information on the `syntax` command and the use of `if`.

As in the previous example, reasonable initial values for δ and ρ are 0.5 and 1, respectively. Conditional on those values, (1) can be rewritten as

$$\beta_0 = \ln Q_i + \ln(0.5K_i^{-1} + 0.5L_i^{-1}) - \epsilon_i \tag{2}$$

so a good initial value for β_0 is the mean of the right-hand side of (2) ignoring ϵ_i. Lines 7–10 of the function evaluator program calculate that mean and store it in a local macro. Notice the use of `if` in the `summarize` statement so that the mean is calculated only for the estimation sample.

The final part of the program returns two macros. The macro `title` is optional and defines a short description of the model that will be displayed in the output immediately above the table of parameter estimates. The macro `eq` is required and defines the substitutable expression that `nl` will use. If the expression is short, you can define it all at once. However, because the expression used here is somewhat lengthy, defining local macros and then building up the final expression from them is easier.

To verify that there are no errors in your program, you can call it directly and then use `return list`:

```
. use http://www.stata-press.com/data/r12/production
. nlces lnoutput capital labor
  (output omitted)
. return list
macros:
             r(title) : "CES ftn., ln Q=lnoutput, K=capital, L=labor"
                r(eq) : "lnoutput = {b0=3.711606264663641} - 1/{rho=1}*ln({delt
> a=0.5}*capital^(-1*{rho}) + (1-{delta})*labor^(-1*{rho}))"
```

The macro `r(eq)` contains the same substitutable expression that we specified at the command line in the preceding example, except for the initial value for `b0`. In short, an `nl` substitutable expression program should return in `r(eq)` the same substitutable expression you would type at the command line. The only difference is that when writing a substitutable expression program, you do not bind the entire expression inside parentheses.

Having written the program, you can use it by typing

```
. nl ces: lnoutput capital labor
```

(There is a space between `nl` and `ces`.) The output is identical to that shown in example 1, save for the title defined in the function evaluator program that appears immediately above the table of parameter estimates.

❑ Technical note

You will want to store `nlces` as an ado-file called `nlces.ado`. The alternative is to type the code into Stata interactively or to place the code in a do-file. While those alternatives are adequate for occasional use, if you save the program as an ado-file, you can use the function anytime you use Stata without having to redefine the program. When `nl` attempts to execute `nlces`, if the program is not in Stata's memory, Stata will search the disk(s) for an ado-file of the same name and, if found, automatically load it. All you have to do is name the file with the `.ado` suffix and then place it in a directory where Stata will find it. You should put the file in the directory Stata reserves for user-written ado-files, which, depending on your operating system, is `c:\ado\personal` (Windows), `~/ado/personal` (Unix), or `~:ado:personal` (Mac). See [U] **17 Ado-files**. ❑

Sometimes you may want to pass additional options to the substitutable expression program. You can modify the `syntax` statement of your program to accept whatever options you wish. Then when you call `nl` with the syntax

```
. nl func_prog: varlist, options
```

any *options* that are not recognized by `nl` (see the table of options at the beginning of this entry) are passed on to your function evaluator program. The only other restriction is that your program cannot accept an option named `at` because `nl` uses that option with function evaluator programs.

Built-in functions

Some functions are used so often that `nl` has them built in so that you do not need to write them yourself. `nl` automatically chooses initial values for the parameters, though you can use the `initial(...)` option to override them.

Three alternatives are provided for exponential regression with one asymptote:

`exp3`	$y_i = \beta_0 + \beta_1 \beta_2^{x_i} + \epsilon_i$
`exp2`	$y_i = \beta_1 \beta_2^{x_i} + \epsilon_i$
`exp2a`	$y_i = \beta_1 \left(1 - \beta_2^{x_i}\right) + \epsilon_i$

For instance, typing `nl exp3: ras dvl` fits the three-parameter exponential model (parameters β_0, β_1, and β_2) using $y_i =$ `ras` and $x_i =$ `dvl`.

Two alternatives are provided for the logistic function (symmetric sigmoid shape; not to be confused with logistic regression):

`log4`	$y_i = \beta_0 + \beta_1 \Big/ \Big[1 + \exp\big\{-\beta_2(x_i - \beta_3)\big\}\Big] + \epsilon_i$
`log3`	$y_i = \beta_1 \Big/ \Big[1 + \exp\big\{-\beta_2(x_i - \beta_3)\big\}\Big] + \epsilon_i$

Finally, two alternatives are provided for the Gompertz function (asymmetric sigmoid shape):

`gom4`	$y_i = \beta_0 + \beta_1 \exp\Big[-\exp\big\{-\beta_2(x_i - \beta_3)\big\}\Big] + \epsilon_i$
`gom3`	$y_i = \beta_1 \exp\Big[-\exp\big\{-\beta_2(x_i - \beta_3)\big\}\Big] + \epsilon_i$

Lognormal errors

A nonlinear model with errors that are independent and identically distributed normal may be written

$$y_i = f(\mathbf{x}_i, \boldsymbol{\beta}) + u_i, \qquad u_i \sim N(0, \sigma^2) \tag{3}$$

for $i = 1, \ldots, n$. If the y_i are thought to have a k-shifted lognormal instead of a normal distribution—that is, $\ln(y_i - k) \sim N(\zeta_i, \tau^2)$, and the systematic part $f(\mathbf{x}_i, \boldsymbol{\beta})$ of the original model is still thought appropriate for y_i—the model becomes

$$\ln(y_i - k) = \zeta_i + v_i = \ln\big\{f(\mathbf{x}_i, \boldsymbol{\beta}) - k\big\} + v_i, \quad v_i \sim N(0, \tau^2) \tag{4}$$

This model is fit if `lnlsq(`k`)` is specified.

If model (4) is correct, the variance of $(y_i - k)$ is proportional to $\big\{f(\mathbf{x}_i, \boldsymbol{\beta}) - k\big\}^2$. Probably the most common case is $k = 0$, sometimes called "proportional errors" because the standard error of y_i is proportional to its expectation, $f(\mathbf{x}_i, \boldsymbol{\beta})$. Assuming that the value of k is known, (4) is just another nonlinear model in $\boldsymbol{\beta}$, and it may be fit as usual. However, we may wish to compare the fit of (3) with that of (4) using the residual sum of squares (RSS) or the deviance D, $D = -2\times$ log-likelihood, from each model. To do so, we must allow for the change in scale introduced by the log transformation.

Assuming, then, the y_i to be normally distributed, Atkinson (1985, 85–87, 184), by considering the Jacobian $\prod |\partial \ln(y_i - k)/\partial y_i|$, showed that multiplying both sides of (4) by the geometric mean of $y_i - k$, $\dot{y}$, gives residuals on the same scale as those of y_i. The geometric mean is given by

$$\dot{y} = e^{n^{-1} \sum \ln(y_i - k)}$$

which is a constant for a given dataset. The residual deviance for (3) and for (4) may be expressed as

$$D(\widehat{\boldsymbol{\beta}}) = \Big\{1 + \ln(2\pi\widehat{\sigma}^2)\Big\} n \tag{5}$$

where $\widehat{\boldsymbol{\beta}}$ is the maximum likelihood estimate (MLE) of $\boldsymbol{\beta}$ for each model and $n\widehat{\sigma}^2$ is the RSS from (3), or that from (4) multiplied by $\dot{y}^2$.

Because (3) and (4) are models with different error structures but the same functional form, the arithmetic difference in their RSS or deviances is not easily tested for statistical significance. However, if the deviance difference is large (>4, say), we would naturally prefer the model with the smaller deviance. Of course, the residuals for each model should be examined for departures from assumptions (nonconstant variance, nonnormality, serial correlations, etc.) in the usual way.

Alternatively, consider modeling

$$E(y_i) = 1/(C + Ae^{Bx_i}) \tag{6}$$

$$E(1/y_i) = E(y'_i) = C + Ae^{Bx_i} \tag{7}$$

where C, A, and B are parameters to be estimated. Using the data $(y, x) = (0.04, 5)$, $(0.06, 12)$, $(0.08, 25)$, $(0.1, 35)$, $(0.15, 42)$, $(0.2, 48)$, $(0.25, 60)$, $(0.3, 75)$, and $(0.5, 120)$ (Danuso 1991), fitting the models yields

Model	C	A	B	RSS	Deviance
(6)	1.781	25.74	−0.03926	−0.001640	−51.95
(6) with `lnlsq(0)`	1.799	25.45	−0.04051	−0.001431	−53.18
(7)	1.781	25.74	−0.03926	8.197	24.70
(7) with `lnlsq(0)`	1.799	27.45	−0.04051	3.651	17.42

There is little to choose between the two versions of the logistic model (6), whereas for the exponential model (7), the fit using `lnlsq(0)` is much better (a deviance difference of 7.28). The reciprocal transformation has introduced heteroskedasticity into y'_i, which is countered by the proportional errors property of the lognormal distribution implicit in `lnlsq(0)`. The deviances are not comparable between the logistic and exponential models because the change of scale has not been allowed for, although in principle it could be.

Other uses

Even if you are fitting linear regression models, you may find that `nl` can save you some typing. Because you specify the parameters of your model explicitly, you can impose constraints on them directly.

▷ Example 2

In example 2 of [R] **cnsreg**, we showed how to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\texttt{price} + \beta_2\texttt{weight} + \beta_3\texttt{displ} + \beta_4\texttt{gear\_ratio} + \beta_5\texttt{foreign} + \beta_6\texttt{length} + u$$

subject to the constraints

$$\beta_1 = \beta_2 = \beta_3 = \beta_6$$
$$\beta_4 = -\beta_5 = \beta_0/20$$

An alternative way is to use `nl`:

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. nl (mpg = {b0} + {b1}*price + {b1}*weight + {b1}*displ +
> {b0}/20*gear_ratio - {b0}/20*foreign + {b1}*length)
(obs = 74)
Iteration 0:  residual SS =  1578.522
Iteration 1:  residual SS =  1578.522
```

Source	SS	df	MS		
Model	34429.4777	2	17214.7389	Number of obs =	74
Residual	1578.52226	72	21.9239203	R-squared =	0.9562
				Adj R-squared =	0.9549
Total	36008	74	486.594595	Root MSE =	4.682299
				Res. dev. =	436.4562

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
/b0	26.52229	1.375178	19.29	0.000	23.78092	29.26365
/b1	-.000923	.0001534	-6.02	0.000	-.0012288	-.0006172

The point estimates and standard errors for β_0 and β_1 are identical to those reported in example 2 of [R] **cnsreg**. To get the estimate for β_4, we can use `nlcom`:

```
. nlcom _b[/b0]/20
       _nl_1:  _b[/b0]/20
```

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
_nl_1	1.326114	.0687589	19.29	0.000	1.189046	1.463183

The advantage to using `nl` is that we do not need to use the `constraint` command six times. ◁

`nl` is also a useful tool when doing exploratory data analysis. For example, you may want to run a regression of `y` on a function of `x`, though you have not decided whether to use sqrt(`x`) or ln(`x`). You can use `nl` to run both regressions without having first to generate two new variables:

```
. nl (y = {b0} + {b1}*ln(x))
. nl (y = {b0} + {b1}*sqrt(x))
```

Poi (2008) shows the advantages of using `nl` when marginal effects of transformed variables are desired as well.

Weights

Weights are specified in the usual way—analytic and frequency weights as well as `iweights` are supported; see [U] **20.22 Weighted estimation**. Use of analytic weights implies that the y_i have different variances. Therefore, model (3) may be rewritten as

$$y_i = f(\mathbf{x}_i, \boldsymbol{\beta}) + u_i, \qquad u_i \sim N(0, \sigma^2/w_i) \tag{3a}$$

where w_i are (positive) weights, assumed to be known and normalized such that their sum equals the number of observations. The residual deviance for (3a) is

$$D(\widehat{\boldsymbol{\beta}}) = \{1 + \ln(2\pi\widehat{\sigma}^2)\}n - \sum \ln(w_i) \tag{5a}$$

[compare with (5)], where

$$n\widehat{\sigma}^2 = \text{RSS} = \sum w_i\{y_i - f(\mathbf{x}_i, \widehat{\boldsymbol{\beta}})\}^2$$

Defining and fitting a model equivalent to (4) when weights have been specified as in (3a) is not straightforward and has not been attempted. Thus deviances using and not using the `lnlsq()` option may not be strictly comparable when analytic weights (other than 0 and 1) are used.

You do not need to modify your substitutable expression in any way to use weights. If, however, you write a substitutable expression program, then you should account for weights when obtaining initial values. When `nl` calls your program, it passes whatever weight expression (if any) was specified by the user. Here is an outline of a substitutable expression program that accepts weights:

```
program nl name, rclass
        version 12
        syntax varlist [aw fw iw] if
        ...
        // Obtain initial values allowing weights
        // Use the syntax [‘weight’‘exp’].  For example,
        summarize  varname [‘weight’‘exp’] ‘if’
        regress  depvar  varlist [‘weight’‘exp’] ‘if’
        ...
        // Return substitutable expression
        return local eq "substitutable expression"
        return local title "description of estimator"
end
```

For details on how the `syntax` command processes weight expressions, see [P] **syntax**.

Potential errors

`nl` is reasonably robust to the inability of your nonlinear function to be evaluated at some parameter values. `nl` does assume that your function can be evaluated at the initial values of the parameters. If your function cannot be evaluated at the initial values, an error message is issued with return code 480. Recall that if you do not specify an initial value for a parameter, then `nl` initializes it to zero. Many nonlinear functions cannot be evaluated when some parameters are zero, so in those cases specifying alternative initial values is crucial.

Thereafter, as `nl` changes the parameter values, it monitors your function for unexpected missing values. If these are detected, `nl` backs up. That is, `nl` finds a point between the previous, known-to-be-good parameter vector and the new, known-to-be-bad vector at which the function can be evaluated and continues its iterations from that point.

`nl` requires that once a parameter vector is found where the predictions can be calculated, small changes to the parameter vector be made to calculate numeric derivatives. If a boundary is encountered at this point, an error message is issued with return code 481.

When specifying `lnlsq()`, an attempt to take logarithms of $y_i - k$ when $y_i \leq k$ results in an error message with return code 482.

If `iterate()` iterations are performed and estimates still have not converged, results are presented with a warning, and the return code is set to 430.

If you use the programmed substitutable expression version of `nl` with a function evaluator program, or vice versa, Stata issues an error message. Verify that you are using the syntax appropriate for the program you have.

General comments on fitting nonlinear models

Achieving convergence is often problematic. For example, a unique minimum of the sum-of-squares function may not exist. Much literature exists on different algorithms that have been used, on strategies for obtaining good initial parameter values, and on tricks for parameterizing the model to make its behavior as linear-like as possible. Selected references are Kennedy and Gentle (1980, chap. 10) for computational matters and Ross (1990) and Ratkowsky (1983) for all three aspects. Ratkowsky's book is particularly clear and approachable, with useful discussion on the meaning and practical implications of intrinsic and parameter-effects nonlinearity. An excellent text on nonlinear estimation is Gallant (1987). Also see Davidson and MacKinnon (1993 and 2004).

To enhance the success of `nl`, pay attention to the form of the model fit, along the lines of Ratkowsky and Ross. For example, Ratkowsky (1983, 49–59) analyzes three possible three-parameter yield-density models for plant growth:

$$E(y_i) = \begin{cases} (\alpha + \beta x_i)^{-1/\theta} \\ (\alpha + \beta x_i + \gamma x_i^2)^{-1} \\ (\alpha + \beta x_i^{\phi})^{-1} \end{cases}$$

All three models give similar fits. However, he shows that the second formulation is dramatically more linear-like than the other two and therefore has better convergence properties. In addition, the parameter estimates are virtually unbiased and normally distributed, and the asymptotic approximation to the standard errors, correlations, and confidence intervals is much more accurate than for the other models. Even within a given model, the way the parameters are expressed (for example, ϕ^{x_i} or $e^{\theta x_i}$) affects the degree of linearity and convergence behavior.

Function evaluator programs

Occasionally, a nonlinear function may be so complex that writing a substitutable expression for it is impractical. For example, there could be many parameters in the model. Alternatively, if you are implementing a two-step estimator, writing a substitutable expression may be altogether impossible. Function evaluator programs can be used in these situations.

`nl` will pass to your function evaluator program a list of variables, a weight expression, a variable marking the estimation sample, and a vector of parameters. Your program is to replace the dependent variable, which is the first variable in the variables list, with the values of the nonlinear function evaluated at those parameters. As with substitutable expression programs, the first two letters of the name must be `nl`.

To focus on the mechanics of the function evaluator program, again let's compare the CES production function to the previous examples. The function evaluator program is

```
program nlces2
        version 12
        syntax varlist(min=3 max=3) if, at(name)
        local logout : word 1 of `varlist'
        local capital : word 2 of `varlist'
        local labor : word 3 of `varlist'
        // Retrieve parameters out of at matrix
        tempname b0 rho delta
        scalar `b0' = `at'[1, 1]
        scalar `rho' = `at'[1, 2]
        scalar `delta' = `at'[1, 3]
        tempvar kterm lterm
        generate double `kterm' = `delta'*`capital'^(-1*`rho') `if'
        generate double `lterm' = (1-`delta')*`labor'^(-1*`rho') `if'
        // Fill in dependent variable
        replace `logout' = `b0' - 1/`rho'*ln(`kterm' + `lterm') `if'
end
```

Unlike the previous `nlces` program, this one is not declared to be r-class. The `syntax` statement again accepts three variables: one for log output, one for capital, and one for labor. An `if` *exp* is again required because `nl` will pass a binary variable marking the estimation sample. All function evaluator programs must accept an option named `at()` that takes a `name` as an argument—that is how `nl` passes the parameter vector to your program.

The next part of the program retrieves the output, labor, and capital variables from the variables list. It then breaks up the temporary matrix `at` and retrieves the parameters `b0`, `rho`, and `delta`. Pay careful attention to the order in which the parameters refer to the columns of the `at` matrix because that will affect the syntax you use with `nl`. The temporary names you use inside this program are immaterial, however.

The rest of the program computes the nonlinear function, using some temporary variables to hold intermediate results. The final line of the program then replaces the dependent variable with the values of the function. Notice the use of `'if'` to restrict attention to the estimation sample. `nl` makes a copy of your dependent variable so that when the command is finished your data are left unchanged.

To use the program and fit your model, you type

```
. use http://www.stata-press.com/data/r12/production, clear
. nl ces2 @ lnoutput capital labor, parameters(b0 rho delta)
> initial(b0 0 rho 1 delta 0.5)
```

The output is again identical to that shown in example 1. The order in which the parameters were specified in the `parameters()` option is the same in which they are retrieved from the `at` matrix in the program. To initialize them, you simply list the parameter name, a space, the initial value, and so on.

If you use the `nparameters()` option instead of the `parameters()` option, the parameters are named `b1`, `b2`, ..., `b`k, where k is the number of parameters. Thus you could have typed

```
. nl ces2 @ lnoutput capital labor, nparameters(3) initial(b1 0 b2 1 b3 0.5)
```

With that syntax, the parameters called `b0`, `rho`, and `delta` in the program will be labeled `b1`, `b2`, and `b3`, respectively. In programming situations or if there are many parameters, instead of listing the parameter names and initial values in the `initial()` option, you may find it more convenient to pass a column vector. In those cases, you could type

```
. matrix myvals = (0, 1, 0.5)
. nl ces2 @ lnoutput capital labor, nparameters(3) initial(myvals)
```

In summary, a function evaluator program receives a list of variables, the first of which is the dependent variable that you are to replace with the values of your nonlinear function. Additionally, it must accept an `if` *exp*, as well as an option named `at` that will contain the vector of parameters at which `nl` wants the function evaluated. You are then free to do whatever is necessary to evaluate your function and replace the dependent variable.

If you wish to use weights, your function evaluator program's `syntax` statement must accept them. If your program consists only of, for example, `generate` statements, you need not do anything with the weights passed to your program. However, if in calculating the nonlinear function you use commands such as `summarize` or `regress`, then you will want to use the weights with those commands.

As with substitutable expression programs, `nl` will pass to it any options specified that `nl` does not accept, providing you with a way to pass more information to your function.

❑ Technical note

Before version 9 of Stata, the `nl` command used a different syntax, which required you to write an *nlfcn* program, and it did not have a syntax for interactive use other than the seven functions that were built-in. The old syntax of `nl` still works, and you can still use those *nlfcn* programs. If `nl` does not see a colon, an at sign, or a set of parentheses surrounding the equation in your command, it assumes that the old syntax is being used.

The current version of `nl` uses scalars and matrices to store intermediate calculations instead of local and global macros as the old version did, so the current version produces more accurate results. In practice, however, any discrepancies are likely to be small.

Methods and formulas

`nl` is implemented as an ado-file.

The derivation here is based on Davidson and MacKinnon (2004, chap. 6). Let $\boldsymbol{\beta}$ denote the $k \times 1$ vector of parameters, and write the regression function using matrix notation as $\mathbf{y} = \mathbf{f}(\mathbf{x}, \boldsymbol{\beta}) + \mathbf{u}$ so that the objective function can be written as

$$\text{SSR}(\boldsymbol{\beta}) = \{\mathbf{y} - \mathbf{f}(\mathbf{x}, \boldsymbol{\beta})\}' \, \mathbf{D} \, \{\mathbf{y} - \mathbf{f}(\mathbf{x}, \boldsymbol{\beta})\}$$

The $\mathbf{D}$ matrix contains the weights and is defined in [R] **regress**; if no weights are specified, then $\mathbf{D}$ is the $N \times N$ identity matrix. Taking a second-order Taylor series expansion centered at $\boldsymbol{\beta}_0$ yields

$$\text{SSR}(\boldsymbol{\beta}) \approx \text{SSR}(\boldsymbol{\beta}_0) + \mathbf{g}'(\boldsymbol{\beta}_0)(\boldsymbol{\beta} - \boldsymbol{\beta}_0) + \frac{1}{2}(\boldsymbol{\beta} - \boldsymbol{\beta}_0)'\mathbf{H}(\boldsymbol{\beta}_0)(\boldsymbol{\beta} - \boldsymbol{\beta}_0) \tag{8}$$

where $\mathbf{g}(\boldsymbol{\beta}_0)$ denotes the $k \times 1$ gradient of $\text{SSR}(\boldsymbol{\beta})$ evaluated at $\boldsymbol{\beta}_0$ and $\mathbf{H}(\boldsymbol{\beta}_0)$ denotes the $k \times k$ Hessian of $\text{SSR}(\boldsymbol{\beta})$ evaluated at $\boldsymbol{\beta}_0$. Letting $\mathbf{X}$ denote the $N \times k$ matrix of derivatives of $\mathbf{f}(\mathbf{x}, \boldsymbol{\beta})$ with respect to $\boldsymbol{\beta}$, the gradient $\mathbf{g}(\boldsymbol{\beta})$ is

$$\mathbf{g}(\boldsymbol{\beta}) = -2\mathbf{X}'\mathbf{D}\mathbf{u} \tag{9}$$

$\mathbf{X}$ and $\mathbf{u}$ are obviously functions of $\boldsymbol{\beta}$, though for notational simplicity that dependence is not shown explicitly. The (m, n) element of the Hessian can be written

$$H_{mn}(\boldsymbol{\beta}) = -2 \sum_{i=1}^{i=N} d_{ii} \left[\frac{\partial^2 f_i}{\partial \beta_m \partial \beta_n} u_i - X_{im} X_{in} \right] \tag{10}$$

where d_{ii} is the ith diagonal element of $\mathbf{D}$. As discussed in Davidson and MacKinnon (2004, chap. 6), the first term inside the brackets of (10) has expectation zero, so the Hessian can be approximated as

$$\mathbf{H}(\boldsymbol{\beta}) = 2\mathbf{X}'\mathbf{D}\mathbf{X} \tag{11}$$

Differentiating the Taylor series expansion of $\text{SSR}(\boldsymbol{\beta})$ shown in (8) yields the first-order condition for a minimum

$$\mathbf{g}(\boldsymbol{\beta}_0) + \mathbf{H}(\boldsymbol{\beta}_0)(\boldsymbol{\beta} - \boldsymbol{\beta}_0) = \mathbf{0}$$

which suggests the iterative procedure

$$\boldsymbol{\beta}_{j+1} = \boldsymbol{\beta}_j - \alpha \mathbf{H}^{-1}(\boldsymbol{\beta}_j)\mathbf{g}(\boldsymbol{\beta}_j) \tag{12}$$

where α is a "step size" parameter chosen at each iteration to improve convergence. Using (9) and (11), we can write (12) as

$$\boldsymbol{\beta}_{j+1} = \boldsymbol{\beta}_j + \alpha(\mathbf{X}'\mathbf{D}\mathbf{X})^{-1}\mathbf{X}'\mathbf{D}\mathbf{u} \tag{13}$$

where $\mathbf{X}$ and $\mathbf{u}$ are evaluated at $\boldsymbol{\beta}_j$. Apart from the scalar α, the second term on the right-hand side of (13) can be computed via a (weighted) regression of the columns of $\mathbf{X}$ on the errors. `nl` computes the derivatives numerically and then calls `regress`. At each iteration, α is set to one, and a candidate value $\boldsymbol{\beta}^*_{j+1}$ is computed by (13). If $\text{SSR}(\boldsymbol{\beta}^*_{j+1}) < \text{SSR}(\boldsymbol{\beta}_j)$, then $\boldsymbol{\beta}_{j+1} = \boldsymbol{\beta}^*_{j+1}$ and the iteration is complete. Otherwise, α is halved, a new $\boldsymbol{\beta}^*_{j+1}$ is calculated, and the process is repeated. Convergence is declared when $\alpha|\beta_{j+1,m}| \leq \epsilon(|\beta_{jm}| + \tau)$ for all $m = 1, \ldots, k$. `nl` uses $\tau = 10^{-3}$ and, by default, $\epsilon = 10^{-5}$, though you can specify an alternative value of ϵ with the `eps()` option.

As derived, for example, in Davidson and MacKinnon (2004, chap. 6), an expedient way to obtain the covariance matrix is to compute $\mathbf{u}$ and the columns of $\mathbf{X}$ at the final estimate $\widehat{\boldsymbol{\beta}}$ and then regress that $\mathbf{u}$ on $\mathbf{X}$. The covariance matrix of the estimated parameters of that regression serves as an estimate of $\mathrm{Var}(\widehat{\boldsymbol{\beta}})$. If that regression employs a robust covariance matrix estimator, then the covariance matrix for the parameters of the nonlinear regression will also be robust.

All other statistics are calculated analogously to those in linear regression, except that the nonlinear function $f(\mathbf{x}_i, \boldsymbol{\beta})$ plays the role of the linear function $\mathbf{x}_i'\boldsymbol{\beta}$. See [R] **regress**.

This command supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Acknowledgments

The original version of `nl` was written by Patrick Royston of the MRC Clinical Trials Unit, London, and published in Royston (1992). Francesco Danuso's menu-driven nonlinear regression program (1991) provided the inspiration.

Title

nl postestimation — Postestimation tools for nl

Description

The following postestimation commands are available after `nl`:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`[1]	likelihood-ratio test
`margins`[2]	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions and residuals
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

[2] You must specify the `variables()` option with `nl`.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]

predict [type] { stub* | newvar_1 ... newvar_k } [if] [in], scores
```

where k is the number of parameters in the model.

statistic	Description
Main	
`yhat`	fitted values; the default
`residuals`	residuals
`pr(a,b)`	$\Pr(y_j \mid a < y_j < b)$
`e(a,b)`	$E(y_j \mid a < y_j < b)$
`ystar(a,b)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`yhat`, the default, calculates the fitted values.

`residuals` calculates the residuals.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated. *a* and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`scores` calculates the scores. The jth new variable created will contain the score for the jth parameter in `e(b)`.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Also see

[U] **20 Estimation and postestimation commands**

Title

nlcom — Nonlinear combinations of estimators

Syntax

Nonlinear combination of estimators—one expression

```
nlcom [name:]exp [, options]
```

Nonlinear combinations of estimators—more than one expression

```
nlcom ([name:]exp) [([name:]exp [, options]
```

options	Description
`level(#)`	set confidence level; default is `level(95)`
`iterate(#)`	maximum number of iterations
`post`	post estimation results
display_options	control column formats and line width
`noheader`	suppress output header

`noheader` does not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses. The optional *name* is any valid Stata name and labels the transformations.

exp is a possibly nonlinear expression containing

```
_b[coef]
_b[eqno:coef]
[eqno]coef
[eqno]_b[coef]
```

eqno is

```
##
name
```

coef identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] **11.4.3 Factor variables**. *coef* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

Distinguish between `[]`, which are to be typed, and [ ], which indicate optional arguments.

Menu

Statistics > Postestimation > Nonlinear combinations of estimates

Description

`nlcom` computes point estimates, standard errors, test statistics, significance levels, and confidence intervals for (possibly) nonlinear combinations of parameter estimates after any Stata estimation command. Results are displayed in the usual table format used for displaying estimation results. Calculations are based on the "delta method", an approximation appropriate in large samples.

`nlcom` can be used with `svy` estimation results; see [SVY] **svy postestimation**.

Options

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in calculating numerical derivatives of the transformation(s) with respect to the original parameters. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

`post` causes `nlcom` to behave like a Stata estimation (`eclass`) command. When `post` is specified, `nlcom` will post the vector of transformed estimators and its estimated variance–covariance matrix to `e()`. This option, in essence, makes the transformation permanent. Thus you could, after `posting`, treat the transformed estimation results in the same way as you would treat results from other Stata estimation commands. For example, after posting, you could redisplay the results by typing `nlcom` without any arguments, or use `test` to perform simultaneous tests of hypotheses on linear combinations of the transformed estimators; see [R] **test**.

Specifying `post` clears out the previous estimation results, which can be recovered only by refitting the original model or by storing the estimation results before running `nlcom` and then restoring them; see [R] **estimates store**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following option is available with `nlcom` but is not shown in the dialog box:

`noheader` suppresses the output header.

Remarks

Remarks are presented under the following headings:

Introduction
Basics
Using the post option
Reparameterizing ML estimators for univariate data
nlcom versus eform

Introduction

nlcom and predictnl both use the delta method. They take nonlinear transformations of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of the transformations. nlcom is designed for functions of the parameters, and predictnl is designed for functions of the parameters and of the data, that is, for predictions.

nlcom generalizes lincom (see [R] **lincom**) in two ways. First, nlcom allows the transformations to be nonlinear. Second, nlcom can be used to simultaneously estimate many transformations (whether linear or nonlinear) and to obtain the estimated variance–covariance matrix of these transformations.

Basics

In [R] **lincom**, the following regression was performed:

```
. use http://www.stata-press.com/data/r12/regress
. regress y x1 x2 x3
```

Source	SS	df	MS	Number of obs =	148
				F(3, 144) =	96.12
Model	3259.3561	3	1086.45203	Prob > F =	0.0000
Residual	1627.56282	144	11.3025196	R-squared =	0.6670
				Adj R-squared =	0.6600
Total	4886.91892	147	33.2443464	Root MSE =	3.3619

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
x1	1.457113	1.07461	1.36	0.177	-.666934	3.581161
x2	2.221682	.8610358	2.58	0.011	.5197797	3.923583
x3	-.006139	.0005543	-11.08	0.000	-.0072345	-.0050435
_cons	36.10135	4.382693	8.24	0.000	27.43863	44.76407

Then lincom was used to estimate the difference between the coefficients of x1 and x2:

```
. lincom _b[x2] - _b[x1]
 ( 1) - x1 + x2 = 0
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
(1)	.7645682	.9950282	0.77	0.444	-1.20218	2.731316

It was noted, however, that nonlinear expressions are not allowed with lincom:

```
. lincom _b[x2]/_b[x1]
not possible with test
r(131);
```

Nonlinear transformations are instead estimated using nlcom:

```
. nlcom _b[x2]/_b[x1]
       _nl_1:  _b[x2]/_b[x1]
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
_nl_1	1.524714	.9812848	1.55	0.122	-.4148688	3.464297

❑ Technical note

The notation _b[*name*] is the standard way in Stata to refer to regression coefficients; see [U] **13.5 Accessing coefficients and standard errors**. Some commands, such as `lincom` and `test`, allow you to drop the _b[] and just refer to the coefficients by *name*. `nlcom`, however, requires the full specification _b[*name*]. ❑

Returning to our linear regression example, `nlcom` also allows simultaneous estimation of more than one combination:

```
. nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1]) (_b[x3]/_b[x2])
       _nl_1:  _b[x2]/_b[x1]
       _nl_2:  _b[x3]/_b[x1]
       _nl_3:  _b[x3]/_b[x2]
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
_nl_1	1.524714	.9812848	1.55	0.122	-.4148688	3.464297
_nl_2	-.0042131	.0033483	-1.26	0.210	-.0108313	.002405
_nl_3	-.0027632	.0010695	-2.58	0.011	-.0048772	-.0006493

We can also label the transformations to produce more informative names in the estimation table:

```
. nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1]) (ratio32:_b[x3]/_b[x2])
     ratio21:  _b[x2]/_b[x1]
     ratio31:  _b[x3]/_b[x1]
     ratio32:  _b[x3]/_b[x2]
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
ratio21	1.524714	.9812848	1.55	0.122	-.4148688	3.464297
ratio31	-.0042131	.0033483	-1.26	0.210	-.0108313	.002405
ratio32	-.0027632	.0010695	-2.58	0.011	-.0048772	-.0006493

`nlcom` saves the vector of estimated combinations and its estimated variance–covariance matrix in `r()`.

```
. matrix list r(b)
r(b)[1,3]
       ratio21     ratio31     ratio32
c1   1.5247143  -.00421315  -.00276324
. matrix list r(V)
symmetric r(V)[3,3]
            ratio21     ratio31     ratio32
ratio21   .96291982
ratio31  -.00287781   .00001121
ratio32  -.00014234   2.137e-06   1.144e-06
```

Using the post option

When used with the post option, nlcom saves the estimation vector and variance–covariance matrix in e(), making the transformation permanent:

```
. quietly nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1])
> (ratio32:_b[x3]/_b[x2]), post
. matrix list e(b)
e(b)[1,3]
       ratio21     ratio31     ratio32
y1   1.5247143  -.00421315  -.00276324
. matrix list e(V)
symmetric e(V)[3,3]
            ratio21     ratio31     ratio32
ratio21   .96291982
ratio31  -.00287781   .00001121
ratio32  -.00014234   2.137e-06   1.144e-06
```

After posting, we can proceed as if we had just run a Stata estimation (eclass) command. For instance, we can replay the results,

```
. nlcom
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
ratio21	1.524714	.9812848	1.55	0.122	-.4148688	3.464297
ratio31	-.0042131	.0033483	-1.26	0.210	-.0108313	.002405
ratio32	-.0027632	.0010695	-2.58	0.011	-.0048772	-.0006493

or perform other postestimation tasks in the transformed metric, this time making reference to the new "coefficients":

```
. display _b[ratio31]
-.00421315
. estat vce, correlation
Correlation matrix of coefficients of nlcom model
```

e(V)	ratio21	ratio31	ratio32
ratio21	1.0000		
ratio31	-0.8759	1.0000	
ratio32	-0.1356	0.5969	1.0000

```
. test _b[ratio21] = 1
 ( 1)  ratio21 = 1
       F(  1,   144) =    0.29
            Prob > F =    0.5937
```

We see that testing _b[ratio21]=1 in the transformed metric is equivalent to testing using testnl _b[x2]/_b[x1]=1 in the original metric:

```
. quietly reg y x1 x2 x3
. testnl _b[x2]/_b[x1] = 1
  (1)  _b[x2]/_b[x1] = 1
               F(1, 144) =        0.29
                Prob > F =        0.5937
```

We needed to refit the regression model to recover the original parameter estimates.

❑ Technical note

In a previous technical note, we mentioned that commands such as `lincom` and `test` permit reference to *name* instead of `_b[`*name*`]`. This is not the case when `lincom` and `test` are used after `nlcom, post`. In the above, we used

```
. test _b[ratio21] = 1
```

rather than

```
. test ratio21 = 1
```

which would have returned an error. Consider this a limitation of Stata. For the shorthand notation to work, you need a variable named *name* in the data. In `nlcom`, however, *name* is just a coefficient label that does not necessarily correspond to any variable in the data.

❑

Reparameterizing ML estimators for univariate data

When run using only a response and no covariates, Stata's maximum likelihood (ML) estimation commands will produce ML estimates of the parameters of some assumed univariate distribution for the response. The parameterization, however, is usually not one we are used to dealing with in a nonregression setting. In such cases, `nlcom` can be used to transform the estimation results from a regression model to those from a maximum likelihood estimation of the parameters of a univariate probability distribution in a more familiar metric.

▷ Example 1

Consider the following univariate data on Y = # of traffic accidents at a certain intersection in a given year:

```
. use http://www.stata-press.com/data/r12/trafint
. summarize accidents
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
   accidents |         12    13.83333    14.47778         0         41
```

A quick glance of the output from `summarize` leads us to quickly reject the assumption that Y is distributed as Poisson because the estimated variance of Y is much greater than the estimated mean of Y.

Instead, we choose to model the data as univariate negative binomial, of which a common parameterization is

$$\Pr(Y=y) = \frac{\Gamma(r+y)}{\Gamma(r)\Gamma(y+1)}p^r(1-p)^y \qquad 0 \le p \le 1, \quad r > 0, \quad y = 0, 1, \ldots$$

with

$$E(Y) = \frac{r(1-p)}{p} \qquad \mathrm{Var}(Y) = \frac{r(1-p)}{p^2}$$

There exist no closed-form solutions for the maximum likelihood estimates of p and r, yet they may be estimated by the iterative method of Newton–Raphson. One way to get these estimates would be to write our own Newton–Raphson program for the negative binomial. Another way would be to write our own ML evaluator; see [R] **ml**.

The easiest solution, however, would be to use Stata's existing negative binomial ML regression command, `nbreg`. The only problem with this solution is that `nbreg` estimates a different parameterization of the negative binomial, but we can worry about that later.

```
. nbreg accidents
Fitting Poisson model:
Iteration 0:   log likelihood = -105.05361
Iteration 1:   log likelihood = -105.05361
Fitting constant-only model:
Iteration 0:   log likelihood = -43.948619
Iteration 1:   log likelihood = -43.891483
Iteration 2:   log likelihood =  -43.89144
Iteration 3:   log likelihood =  -43.89144
Fitting full model:
Iteration 0:   log likelihood =  -43.89144
Iteration 1:   log likelihood =  -43.89144
Negative binomial regression                    Number of obs   =         12
                                                LR chi2(0)      =       0.00
Dispersion     = mean                           Prob > chi2     =          .
Log likelihood = -43.89144                      Pseudo R2       =     0.0000
```

accidents	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]

Negative binomial regression                    Number of obs   =         12
                                                LR chi2(0)      =       0.00
Dispersion     = mean                           Prob > chi2     =          .
Log likelihood = -43.89144                      Pseudo R2       =     0.0000
```

accidents	Coef.	Legend
_cons	2.627081	_b[accidents:_cons]
/lnalpha	.1402425	_b[lnalpha:_cons]
alpha	1.150553	

```
Likelihood-ratio test of alpha=0:  chibar2(01) =  122.32 Prob>=chibar2 = 0.000
```

From this output, we see that, when used with univariate data, `nbreg` estimates a regression intercept, β_0, and the logarithm of some parameter α. This parameterization is useful in regression models: β_0 is the intercept meant to be augmented with other terms of the linear predictor, and α is an overdispersion parameter used for comparison with the Poisson regression model.

However, we need to transform $(\beta_0, \ln\alpha)$ to (p, r). Examining *Methods and formulas* of [R] **nbreg** reveals the transformation as

$$p = \{1 + \alpha \exp(\beta_0)\}^{-1} \qquad r = \alpha^{-1}$$

which we apply using `nlcom`:

```
. nlcom (p:1/(1 + exp([lnalpha]_b[_cons] + _b[_cons])))
> (r:exp(-[lnalpha]_b[_cons]))
          p:  1/(1 + exp([lnalpha]_b[_cons] + _b[_cons]))
          r:  exp(-[lnalpha]_b[_cons])
```

accidents	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
p	.0591157	.0292857	2.02	0.044	.0017168	.1165146
r	.8691474	.3639248	2.39	0.017	.1558679	1.582427

Given the invariance of maximum likelihood estimators and the properties of the delta method, the above parameter estimates, standard errors, etc., are precisely those we would have obtained had we instead performed the Newton–Raphson optimization in the (p, r) metric.

◁

❑ Technical note

Note how we referred to the estimate of $\ln\alpha$ above as `[lnalpha]_b[_cons]`. This is not entirely evident from the output of `nbreg`, which is why we redisplayed the results using the `coeflegend` option so that we would know how to refer to the coefficients; [U] **13.5 Accessing coefficients and standard errors**.

❑

nlcom versus eform

Many Stata estimation commands allow you to display exponentiated regression coefficients, some by default, some optionally. Known as "`eform`" in Stata terminology, this reparameterization serves many uses: it gives odds ratios for logistic models, hazard ratios in survival models, incidence-rate ratios in Poisson models, and relative-risk ratios in multinomial logit models, to name a few.

For example, consider the following estimation taken directly from the technical note in [R] **poisson**:

```
. use http://www.stata-press.com/data/r12/airline
. gen lnN = ln(n)
. poisson injuries XYZowned lnN
Iteration 0:   log likelihood = -22.333875
Iteration 1:   log likelihood = -22.332276
Iteration 2:   log likelihood = -22.332276
Poisson regression                              Number of obs   =          9
                                                LR chi2(2)      =      19.15
                                                Prob > chi2     =     0.0001
Log likelihood = -22.332276                     Pseudo R2       =     0.3001
```

injuries	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
XYZowned	.6840667	.3895877	1.76	0.079	-.0795111	1.447645
lnN	1.424169	.3725155	3.82	0.000	.6940517	2.154285
_cons	4.863891	.7090501	6.86	0.000	3.474178	6.253603

When we replay results and specify the `irr` (incidence-rate ratios) option,

```
. poisson, irr
Poisson regression                                Number of obs   =          9
                                                  LR chi2(2)      =      19.15
                                                  Prob > chi2     =     0.0001
Log likelihood = -22.332276                       Pseudo R2       =     0.3001
```

injuries	IRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
XYZowned	1.981921	.7721322	1.76	0.079	.9235678	4.253085
lnN	4.154402	1.547579	3.82	0.000	2.00181	8.621728
_cons	129.5272	91.84126	6.86	0.000	32.2713	519.8828

we obtain the exponentiated regression coefficients and their estimated standard errors.

Contrast this with what we obtain if we exponentiate the coefficients manually by using `nlcom`:

```
. nlcom (E_XYZowned:exp(_b[XYZowned])) (E_lnN:exp(_b[lnN]))
  E_XYZowned:  exp(_b[XYZowned])
      E_lnN:  exp(_b[lnN])
```

injuries	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
E_XYZowned	1.981921	.7721322	2.57	0.010	.4685701	3.495273
E_lnN	4.154402	1.547579	2.68	0.007	1.121203	7.187602

There are three things to note when comparing `poisson, irr` (and `eform` in general) with `nlcom`:

1. The exponentiated coefficients and standard errors are identical. This is certainly good news.
2. The Wald test statistic (`z`) and level of significance are different. When using `poisson, irr` and other related `eform` options, the Wald test does not change from what you would have obtained without the `eform` option, and you can see this by comparing both versions of the `poisson` output given previously.

   When you use `eform`, Stata knows that what is usually desired is a test of

   $$H_0: \exp(\beta) = 1$$

   and not the uninformative-by-comparison

   $$H_0: \exp(\beta) = 0$$

   The test of $H_0: \exp(\beta) = 1$ is asymptotically equivalent to a test of $H_0: \beta = 0$, the Wald test in the original metric, but the latter has better small-sample properties. Thus if you specify `eform`, you get a test of $H_0: \beta = 0$.

   `nlcom`, however, is general. It does not attempt to infer the test of greatest interest for a given transformation, and so a test of

   $$H_0: \text{transformed coefficient} = 0$$

   is always given, regardless of the transformation.
3. You may be surprised to see that, even though the coefficients and standard errors are identical, the confidence intervals (both 95%) are different.

eform confidence intervals are standard confidence intervals with the endpoints transformed. For example, the confidence interval for the coefficient on lnN is $[0.694, 2.154]$, whereas the confidence interval for the incidence-rate ratio due to lnN is $[\exp(0.694), \exp(2.154)] = [2.002, 8.619]$, which, except for some roundoff error, is what we see from the output of poisson, irr. For exponentiated coefficients, confidence intervals based on transform-the-endpoints methodology generally have better small-sample properties than their asymptotically equivalent counterparts.

The transform-the-endpoints method, however, gives valid coverage only when the transformation is monotonic. nlcom uses a more general and asymptotically equivalent method for calculating confidence intervals, as described in *Methods and formulas*.

Saved results

nlcom saves the following in r():

Scalars

r(N)	number of observations
r(df_r)	residual degrees of freedom

Matrices

r(b)	vector of transformed coefficients
r(V)	estimated variance–covariance matrix of the transformed coefficients

If post is specified, nlcom also saves the following in e():

Scalars

e(N)	number of observations
e(df_r)	residual degrees of freedom
e(N_strata)	number of strata L, if used after svy
e(N_psu)	number of sampled PSUs n, if used after svy
e(rank)	rank of e(V)

Macros

e(cmd)	nlcom
e(predict)	program used to implement predict
e(properties)	b V

Matrices

e(b)	vector of transformed coefficients
e(V)	estimated variance–covariance matrix of the transformed coefficients
e(V_srs)	simple-random-sampling-without-replacement (co)variance $\widehat{V}_{\text{srswor}}$, if svy
e(V_srswr)	simple-random-sampling-with-replacement (co)variance $\widehat{V}_{\text{srswr}}$, if svy and fpc()
e(V_msp)	misspecification (co)variance $\widehat{V}_{\text{msp}}$, if svy and available

Functions

e(sample)	marks estimation sample

Methods and formulas

nlcom is implemented as an ado-file.

Given a $1 \times k$ vector of parameter estimates, $\widehat{\boldsymbol{\theta}} = (\widehat{\theta}_1, \ldots, \widehat{\theta}_k)$, consider the estimated p-dimensional transformation

$$g(\widehat{\boldsymbol{\theta}}) = [g_1(\widehat{\boldsymbol{\theta}}), g_2(\widehat{\boldsymbol{\theta}}), \ldots, g_p(\widehat{\boldsymbol{\theta}})]$$

The estimated variance–covariance of $g(\widehat{\boldsymbol{\theta}})$ is given by

$$\widehat{\text{Var}}\left\{g(\widehat{\boldsymbol{\theta}})\right\} = \mathbf{GVG}'$$

where $\mathbf{G}$ is the $p \times k$ matrix of derivatives for which

$$\mathbf{G}_{ij} = \left.\frac{\partial g_i(\boldsymbol{\theta})}{\partial \theta_j}\right|_{\boldsymbol{\theta}=\widehat{\boldsymbol{\theta}}} \qquad i = 1, \ldots, p \qquad j = 1, \ldots, k$$

and $\mathbf{V}$ is the estimated variance–covariance matrix of $\widehat{\boldsymbol{\theta}}$. Standard errors are obtained as the square roots of the variances.

The Wald test statistic for testing

$$H_0 : g_i(\boldsymbol{\theta}) = 0$$

versus the two-sided alternative is given by

$$Z_i = \frac{g_i(\widehat{\boldsymbol{\theta}})}{\left[\widehat{\mathrm{Var}}_{ii}\left\{g(\widehat{\boldsymbol{\theta}})\right\}\right]^{1/2}}$$

When the variance–covariance matrix of $\widehat{\boldsymbol{\theta}}$ is an asymptotic covariance matrix, Z_i is approximately distributed as Gaussian. For linear regression, Z_i is taken to be approximately distributed as $t_{1,r}$ where r is the residual degrees of freedom from the original fitted model.

A $(1-\alpha) \times 100\%$ confidence interval for $g_i(\boldsymbol{\theta})$ is given by

$$g_i(\widehat{\boldsymbol{\theta}}) \pm z_{\alpha/2}\left[\widehat{\mathrm{Var}}_{ii}\left\{g(\widehat{\boldsymbol{\theta}})\right\}\right]^{1/2}$$

for those cases where Z_i is Gaussian and

$$g_i(\widehat{\boldsymbol{\theta}}) \pm t_{\alpha/2,r}\left[\widehat{\mathrm{Var}}_{ii}\left\{g(\widehat{\boldsymbol{\theta}})\right\}\right]^{1/2}$$

for those cases where Z_i is t distributed. z_p is the $1-p$ quantile of the standard normal distribution, and $t_{p,r}$ is the $1-p$ quantile of the t distribution with r degrees of freedom.

Title

nlogit — Nested logit regression

Syntax

Nested logit regression

```
nlogit depvar [indepvars] [if] [in] [weight] [|| lev1_equation
    [|| lev2_equation ...]] || altvar: [byaltvarlist], case(varname) [options]
```

where the syntax of *lev#_equation* is

```
altvar: [byaltvarlist] [, base(# | lbl) estconst]
```

Create variable based on specification of branches

```
nlogitgen newaltvar = altvar (branchlist) [, nolog]
```

where *branchlist* is

```
branch, branch [, branch ...]
```

and *branch* is

```
[label:] alternative [| alternative [| alternative ...]]
```

Display tree structure

```
nlogittree altvarlist [if] [in] [weight] [, choice(depvar) nolabel nobranches]
```

options	Description
Model	
* `case(`*varname*`)`	use *varname* to identify cases
`base(#` | *lbl*`)`	use the specified level or label of *altvar* as the base alternative for the bottom level
`noconstant`	suppress the constant terms for the bottom-level alternatives
`nonnormalized`	use the nonnormalized parameterization
`altwise`	use alternativewise deletion instead of casewise deletion
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`notree`	suppress display of tree-structure output; see also `nolabel` and `nobranches`
`nocnsreport`	do not display constraints
display_options	control column formats and line width
Maximization	
maximize_options	control the maximization process; seldom used

* `case(`*varname*`)` is required.

`bootstrap`, `by`, `jackknife`, `statsby`, and `xi` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`fweights`, `iweights`, and `pweights` are allowed with `nlogit`, and `fweights` are allowed with `nlogittree`; see [U] **11.1.6 weight**. Weights for `nlogit` must be constant within case.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

nlogit

Statistics > Categorical outcomes > Nested logit regression

nlogitgen

Statistics > Categorical outcomes > Setup for nested logit regression

nlogittree

Statistics > Categorical outcomes > Display nested logit tree structure

Description

`nlogit` performs full information maximum-likelihood estimation for nested logit models. These models relax the assumption of independently distributed errors and the independence of irrelevant alternatives inherent in conditional and multinomial logit models by clustering similar alternatives into nests.

By default, `nlogit` uses a parameterization that is consistent with random utility maximization (RUM). Before version 10 of Stata, a nonnormalized version of the nested logit model was fit, which you can request by specifying the `nonnormalized` option.

You must use `nlogitgen` to generate a new categorical variable to specify the branches of the decision tree before calling `nlogit`.

Options

Specification and options for lev#_equation

altvar is a variable identifying alternatives at this level of the hierarchy.

byaltvarlist specifies the variables to be used to compute the by-alternative regression coefficients for that level. For each variable specified in the variable list, there will be one regression coefficient for each alternative of that level of the hierarchy. If the variable is constant across each alternative (a case-specific variable), the regression coefficient associated with the base alternative is not identifiable. These regression coefficients are labeled as (base) in the regression table. If the variable varies among the alternatives, a regression coefficient is estimated for each alternative.

`base(`*#* | *lbl*`)` can be specified in each level equation where it identifies the base alternative to be used at that level. The default is the alternative that has the highest frequency.

If `vce(bootstrap)` or `vce(jackknife)` is specified, you must specify the base alternative for each level that has a *byaltvarlist* or if the constants will be estimated. Doing so ensures that the same model is fit with each call to `nlogit`.

`estconst` applies to all the level equations except the bottom-level equation. Specifying `estconst` requests that constants for each alternative (except the base alternative) be estimated. By default, no constant is estimated at these levels. Constants can be estimated in only one level of the tree hierarchy. If you specify `estconst` for one of the level equations, you must specify `noconstant` for the bottom-level equation.

Options for nlogit

Model

`case(`*varname*`)` specifies the variable that identifies each case. `case()` is required.

`base(`*#* | *lbl*`)` can be specified in each level equation where it identifies the base alternative to be used at that level. The default is the alternative that has the highest frequency.

If `vce(bootstrap)` or `vce(jackknife)` is specified, you must specify the base alternative for each level that has a *byaltvarlist* or if the constants will be estimated. Doing so ensures that the same model is fit with each call to `nlogit`.

`noconstant` applies only to the equation defining the bottom level of the hierarchy. By default, constants are estimated for each alternative of *altvar*, less the base alternative. To suppress the constant terms for this level, specify `noconstant`. If you do not specify `noconstant`, you cannot specify `estconst` for the higher-level equations.

`nonnormalized` requests a nonnormalized parameterization of the model that does not scale the inclusive values by the degree of dissimilarity of the alternatives within each nest. Use this option to replicate results from older versions of Stata. The default is to use the RUM–consistent parameterization.

`altwise` specifies that alternativewise deletion be used when marking out observations because of missing values in your variables. The default is to use casewise deletion. This option does not apply to observations that are marked out by the `if` or `in` qualifier or the `by` prefix.

`constraints(`*constraints*`)`; see [R] **estimation options**.

The inclusive-valued/dissimilarity parameters are parameterized as `ml` ancillary parameters. They are labeled as [*alternative*`_tau`]`_const`, where *alternative* is one of the alternatives defining a branch in the tree. To constrain the inclusive-valued/dissimilarity parameter for alternative `a1` to be, say, equal to alternative `a2`, you would use the following syntax:

```
. constraint 1 [a1_tau]_cons = [a2_tau]_cons
. nlogit ..., constraints(1)
```

`collinear` prevents collinear variables from being dropped. Use this option when you know that you have collinear variables and you are applying `constraints()` to handle the rank reduction. See [R] **estimation options** for details on using `collinear` with `constraints()`.

`nlogit` will not allow you to specify an independent variable in more than one level equation. Specifying the `collinear` option will allow execution to proceed in this case, but it is your responsibility to ensure that the parameters are identified.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

If `vce(robust)` or `vce(cluster` *clustvar*`)` is specified, the likelihood-ratio test for the independence of irrelevant alternatives (IIA) is not computed.

Reporting

`level(#)`; see [R] **estimation options**.

`notree` specifies that the tree structure of the nested logit model not be displayed. See also `nolabel` and `nobranches` below for when `notree` is not specified.

`nocnsreport`; see [R] **estimation options**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, [`no`]`log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The `technique(bhhh)` option is not allowed.

Specification and options for nlogitgen

newaltvar and *altvar* are variables identifying alternatives at each level of the hierarchy.

label defines a label to associate with the branch. If no label is given, a numeric value is used.

alternative specifies an alternative, of *altvar* specified in the syntax, to be included in the branch. It is either a numeric value or the label associated with that value. An example of `nlogitgen` is

```
. nlogitgen type = restaurant(fast: 1 | 2,
> family: CafeEccell | LosNortenos | WingsNmore, fancy: 6 | 7)
```

`nolog` suppresses the display of the iteration log.

Specification and options for nlogittree

Main

altvarlist is a list of alternative variables that define the tree hierarchy. The first variable must define bottom-level alternatives, and the order continues to the variable defining the top-level alternatives.

`choice(`*depvar*`)` defines the choice indicator variable and forces `nlogittree` to compute and display choice frequencies for each bottom-level alternative.

`nolabel` forces `nlogittree` to suppress value labels in tree-structure output.

`nobranches` forces `nlogittree` to suppress drawing branches in the tree-structure output.

Remarks

Remarks are presented under the following headings:

Introduction
Data setup and the tree structure
Estimation
Testing for the IIA
Nonnormalized model

Introduction

`nlogit` performs full information maximum-likelihood estimation for nested logit models. These models relax the assumption of independently distributed errors and the IIA inherent in conditional and multinomial logit models by clustering similar alternatives into nests. Because the nested logit model is a direct generalization of the alternative-specific conditional logit model (also known as McFadden's choice model), you may want to read [R] **asclogit** before continuing.

By default, `nlogit` uses a parameterization that is consistent with RUM. Before version 10 of Stata, a nonnormalized version of the nested logit model was fit, which you can request by specifying the `nonnormalized` option. We recommend using the RUM-consistent version of the model for new projects because it is based on a sound model of consumer behavior.

McFadden (1977, 1981) showed how this model can be derived from a rational choice framework. Amemiya (1985, chap. 9) contains a nice discussion of how this model can be derived under the assumption of utility maximization. Hensher, Rose, and Greene (2005) provide a lucid introduction to choice models including nested logit.

Throughout this entry, we consider a model of restaurant choice. We begin by introducing the data.

▷ Example 1

We have fictional data on 300 families and their choice of seven local restaurants. Freebirds and Mama's Pizza are fast food restaurants; Café Eccell, Los Norteños, and Wings 'N More are family restaurants; and Christopher's and Mad Cows are fancy restaurants. We want to model the decision of where to eat as a function of household income (`income`, in thousands of dollars), the number

of children in the household (kids), the rating of the restaurant according to a local restaurant guide (rating, coded 0–5), the average meal cost per person (cost), and the distance between the household and the restaurant (distance, in miles). income and kids are attributes of the family, rating is an attribute of the alternative (the restaurant), and cost and distance are attributes of the alternative as perceived by the families—that is, each family has its own cost and distance for each restaurant.

We begin by loading the data and listing some of the variables for the first three families:

```
. use http://www.stata-press.com/data/r12/restaurant

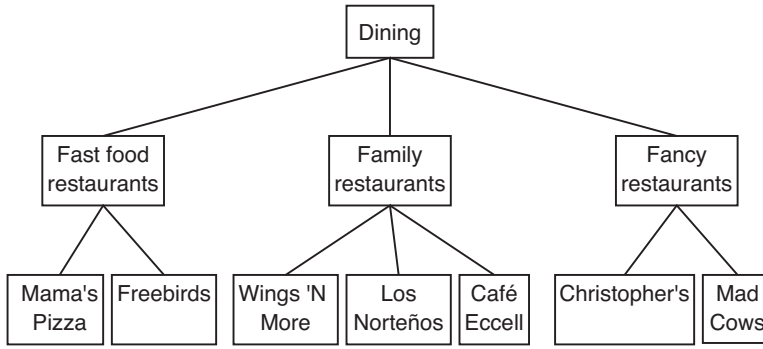
Because each family chose among seven restaurants, there are 7 observations in the dataset for each family. The variable `chosen` is coded 0/1, with 1 indicating the chosen restaurant and 0 otherwise. ◁

We could fit a conditional logit model to our data. Because `income` and `kids` are constant within each family, we would use the `asclogit` command instead of `clogit`. However, the conditional logit may be inappropriate. That model assumes that the random errors are independent, and as a result it forces the odds ratio of any two alternatives to be independent of the other alternatives, a property known as the IIA. We will discuss the IIA assumption in more detail later.

Assuming that unobserved shocks influencing a decision maker's attitude toward one alternative have no effect on his attitudes toward the other alternatives may seem innocuous, but often this assumption is too restrictive. Suppose that when a family was deciding which restaurant to visit, they were pressed for time because of plans to attend a movie later. The unobserved shock (being in a hurry) would raise the likelihood that the family goes to either fast food restaurant (Freebirds or Mama's Pizza). Similarly, another family might be choosing a restaurant to celebrate a birthday and therefore be inclined to attend a fancy restaurant (Christopher's or Mad Cows).

Nested logit models relax the independence assumption and allow us to group alternatives for which unobserved shocks may have concomitant effects. Here we suspect that restaurants should be grouped by type (fast, family, or fancy). The tree structure of a family's decision about where to eat might look like this:



At the bottom of the tree are the individual restaurants, indicating that there are some random shocks that affect a family's decision to eat at each restaurant independently. Above the restaurants are the three types of restaurants, indicating that other random shocks affect the type of restaurant chosen. As is customary when drawing decision trees, at the top level is one box, representing the family making the decision.

We use the following terms to describe nested logit models.

level, or decision level, is the level or stage at which a decision is made. The example above has only two levels. In the first level, a type of restaurant is chosen—fast food, family, or fancy—and in the second level, a specific restaurant is chosen.

bottom level is the level where the final decision is made. In our example, this is when we choose a specific restaurant.

alternative set is the set of all possible alternatives at any given decision level.

bottom alternative set is the set of all possible alternatives at the bottom level. This concept is often referred to as the choice set in the economics-choice literature. In our example, the bottom alternative set is all seven of the specific restaurants.

alternative is a specific alternative within an alternative set. In the first level of our example, "fast food" is an alternative. In the second or bottom level, "Mad Cows" is an alternative. Not all alternatives within an alternative set are available to someone making a choice at a specific stage, only those that are nested within all higher-level decisions.

chosen alternative is the alternative from an alternative set that we observe someone having chosen.

❑ Technical note

Although decision trees in nested logit analysis are often interpreted as implying that the highest-level decisions are made first, followed by decisions at lower levels, and finally the decision among alternatives at the bottom level, no such temporal ordering is implied. See Hensher, Rose, and Greene (2005, chap. 13). In our example, we are not assuming that families first choose whether to attend a fast, family, or fancy restaurant and then choose the particular restaurant; we assume merely that they choose one of the seven restaurants.

❑

Data setup and the tree structure

To fit a nested logit model, you must first create a variable that defines the structure of your decision tree.

▷ Example 2

To run `nlogit`, we need to generate a categorical variable that identifies the first-level set of alternatives: fast food, family restaurants, or fancy restaurants. We can do so easily by using `nlogitgen`.

```
. nlogitgen type = restaurant(fast: Freebirds | MamasPizza,
> family: CafeEccell | LosNortenos| WingsNmore, fancy: Christophers | MadCows)
new variable type is generated with 3 groups
label list lb_type
lb_type:
           1 fast
           2 family
           3 fancy
. nlogittree restaurant type, choice(chosen)
tree structure specified for the nested logit model
 type    N      restaurant    N   k
──────────────────────────────────────
 fast   600 ─┬─ Freebirds    300  12
             └─ MamasPizza   300  15
 family 900 ─┬─ CafeEccell   300  78
             ├─ LosNortenos  300  75
             └─ WingsNmore   300  69
 fancy  600 ─┬─ Christophers 300  27
             └─ MadCows      300  24
──────────────────────────────────────
                     total  2100 300
k = number of times alternative is chosen
N = number of observations at each level
```

The new categorical variable is `type`, which takes on value 1 (fast) if `restaurant` is Freebirds or Mama's Pizza; value 2 (family) if `restaurant` is Café Eccell, Los Norteños, or Wings 'N More; and value 3 (fancy) otherwise. `nlogittree` displays the tree structure.

◁

❑ Technical note

We could also use values instead of value labels of `restaurant` in `nlogitgen`. Value labels are optional, and the default value labels for `type` are `type1`, `type2`, and `type3`. The vertical bar is also optional.

```
. use http://www.stata-press.com/data/r12/restaurant, clear
. nlogitgen type = restaurant(1 2, 3 4 5, 6 7)
new variable type is generated with 3 groups
label list lb_type
lb_type:
           1 type1
           2 type2
           3 type3
```

```
. nlogittree restaurant type
tree structure specified for the nested logit model
 type    N      restaurant     N
──────────────────────────────────
 type1 600 ─┬─ Freebirds     300
            └─ MamasPizza    300
 type2 900 ─┬─ CafeEccell    300
            ├─ LosNortenos   300
            └─ WingsNmore    300
 type3 600 ─┬─ Christophers  300
            └─ MadCows       300
──────────────────────────────────
                     total  2100
N = number of observations at each level
```

❑

In our dataset, every family was able to choose among all seven restaurants. However, in other applications some decision makers may not have been able to choose among all possible alternatives. For example, two cases may have choice hierarchies of

```
      case 1                          case 2
type        restaurant          type        restaurant
──────────────────────          ──────────────────────
fast   ─┬─ Freebirds            fast   ─┬─ Freebirds
        └─ MamasPizza                   └─ MamasPizza
family ─┬─ CafeEccell           family ─┬─ LosNortenos
        ├─ LosNortenos                  └─ WingsNmore
        └─ WingsNmore
fancy  ─┬─ Christophers         fancy  ── Christophers
        └─ MadCows
```

where the second case does not have the restaurant alternatives Café Eccell or Mad Cows available to them. The only restriction is that the relationships between higher- and lower-level alternative sets be the same for all decision makers. In this two-level example, Freebirds and Mama's Pizza are classified as fast food restaurants for both cases; Café Eccell, Los Norteños, and Wings 'N More are family restaurants; and Christopher's and Mad Cows are fancy restaurants. `nlogit` requires only that hierarchy be maintained for all cases.

Estimation

▷ Example 3

With our `type` variable created that defines the three types of restaurants, we can now examine how the alternative-specific attributes (`cost`, `rating`, and `distance`) apply to the bottom alternative set (the seven restaurants) and how family-specific attributes (`income` and `kid`) apply to the alternative set at the first decision level (the three types of restaurants).

```
. nlogit chosen cost rating distance || type: income kids, base(family) ||
> restaurant:, noconstant case(family_id)
tree structure specified for the nested logit model
 type    N      restaurant    N   k
──────────────────────────────────────
 fast   600 ─┬─ Freebirds    300  12
             └─ MamasPizza   300  15
 family 900 ─┬─ CafeEccell   300  78
             ├─ LosNortenos  300  75
             └─ WingsNmore   300  69
 fancy  600 ─┬─ Christophers 300  27
             └─ MadCows      300  24
──────────────────────────────────────
                     total  2100 300

LR test for IIA (tau = 1): chi2(3) = 6.87 Prob > chi2 = 0.0762

First, let's examine how we called `nlogit`. The delimiters (`||`) separate equations. The first equation specifies the dependent variable, `chosen`, and three alternative-specific variables, `cost`,

rating, and distance. We refer to these variables as alternative-specific because they vary among the bottom-level alternatives, the restaurants. We obtain one parameter estimate for each variable. These estimates are listed in the equation subtable labeled restaurant.

For the second equation, we specify the type variable. It identifies the first-level alternatives, the restaurant types. Following the colon after type, we specify two case-specific variables, income and kids. Here we obtain a parameter estimate for each variable for each alternative at this level. That is why we call these variable lists *by-alternative* variables. Because income and kids do not vary within each case, to identify the model one alternative's set of parameters must be set to zero. We specified the base(family) option with this equation to restrict the parameters for the family alternative.

The variable identifying the bottom-level alternatives, restaurant, is specified after the second equation delimiter. We do not specify any variables after the colon delimiter at this level. Had we specified variables here, we would have obtained an estimate for each variable in each equation. As we will see below, these variables parameterize the constant term in the utility equation for each bottom-level alternative. The noconstant option suppresses bottom-level alternative-specific constant terms.

Near the bottom of the output are the dissimilarity parameters, which measure the degree of correlation of random shocks within each of the three types of restaurants. Dissimilarity parameters greater than one imply that the model is inconsistent with RUM; Hensher, Rose, and Greene (2005, sec. 13.6) discuss this in detail. We will ignore the fact that all our dissimilarity parameters exceed one.

The conditional logit model is a special case of nested logit in which all the dissimilarity parameters are equal to one. At the bottom of the output, we find a likelihood-ratio test of this hypothesis. Here we have mixed evidence of the null hypothesis that all the parameters are one. Equivalently, the property known as the IIA imposed by the conditional logit model holds if and only if all dissimilarity parameters are equal to one. We discuss the IIA in more detail now.

◁

Testing for the IIA

The IIA is a property of the multinomial and conditional logit models that forces the odds of choosing one alternative over another to be independent of the other alternatives. For simplicity, suppose that a family was choosing only between Freebirds and Mama's Pizza, and the family was equally likely to choose either of the restaurants. The probability of going to each restaurant is 50%. Now suppose that Bill's Burritos opens up next door to Freebirds, which is also a burrito restaurant. If the IIA holds, then the probability of going to each restaurant must now be 33.33% so that the family remains equally likely to go to Mama's Pizza or Freebirds.

The IIA may sometimes be a plausible assumption. However, a more likely scenario would be for the probability of going to Mama's Pizza to remain at 50% and the probabilities of going to Freebirds and Bill's Burritos to be 25% each, because the two restaurants are next door to each other and serve the same food. Nested logit analysis would allow us to relax the IIA assumption of conditional logit. We could group Bill's Burritos and Freebirds into one nest that encompasses all burrito restaurants and create a second nest for pizzerias.

The IIA is a consequence of assuming that the errors are independent and identically distributed (i.i.d.). Because the errors are i.i.d., they cannot contain any alternative-specific unobserved information, and therefore adding a new alternative cannot affect the relationship between a pair of existing alternatives.

In the previous example, we saw that a joint test that the dissimilarity parameters were equal to one is one way to test for IIA. However, that test required us to specify a decision tree for the

nested logit model, and different specifications could lead to conflicting results of the test. Hausman and McFadden (1984) suggest that if part of the choice set truly is irrelevant with respect to the other alternatives, omitting that subset from the conditional logit model will not lead to inconsistent estimates. Therefore, Hausman's (1978) specification test can be used to test for IIA, and this test will not be sensitive to the tree structure we specify for a nested logit model.

▷ Example 4

We want to test the IIA for the subset of family restaurants against the alternatives of fast food and fancy restaurants. To do so, we need to use Stata's `hausman` command; see [R] **hausman**.

We first run the estimation on the full bottom alternative set, save the results by using `estimates store`, and then run the estimation on the bottom alternative set, excluding the alternatives of family restaurants. We then run the `hausman` test.

```

Similar to our findings in example 3, the results of the test of the IIA are mixed. We cannot reject the IIA at the commonly used 5% significance level, but we could at the 10% level. Substantively, a significant test result suggests that the odds of going to one of the fancy restaurants versus going to one of the fast food restaurants changes if we include the family restaurants in the alternative set and that a nested logit specification may be warranted.

◁

Nonnormalized model

Previous versions of Stata fit a nonnormalized nested logit model that is available via the `nonnormalized` option. The nonnormalized version is presented in, for example, Greene (2012, 768–770). Here we outline the differences between the RUM-consistent and nonnormalized models. Our discussion follows Heiss (2002) and assumes the decision tree has two levels, with M alternatives at the upper level and a total of J alternatives at the bottom level.

In a RUM framework, by consuming alternative j, decision maker i obtains utility

$$U_{ij} = V_{ij} + \epsilon_{ij} = \alpha_j + \mathbf{x}_{ij}\boldsymbol{\beta}_j + \mathbf{z}_i\boldsymbol{\gamma}_j + \epsilon_{ij}$$

where V_{ij} is the deterministic part of utility and ϵ_{ij} is the random part. $\mathbf{x}_{ij}$ are alternative-specific variables and $\mathbf{z}_i$ are case-specific variables. The set of errors $\epsilon_{i1}, \ldots, \epsilon_{iJ}$ are assumed to follow the generalized extreme-value (GEV) distribution, which is a generalization of the type 1 extreme-value distribution that allows for alternatives within nests of the tree structure to be correlated. Let ρ_m denote the correlation in nest m, and define the dissimilarity parameter $\tau_m = \sqrt{1-\rho_m}$. $\tau_m = 0$ implies that the alternatives in nest m are perfectly correlated, whereas $\tau_m = 1$ implies independence.

The *inclusive value* for the mth nest corresponds to the expected value of the utility that decision maker i obtains by consuming an alternative in nest m. Denote this value by IV_m:

$$\text{IV}_m = \ln \sum_{j \in B_m} \exp\left(V_k/\tau_m\right) \tag{1}$$

where B_m denotes the set of alternatives in nest m. Given the inclusive values, we can show that the probability that random-utility–maximizing decision maker i chooses alternative j is

$$\Pr_j = \frac{\exp\left\{V_j/\tau(j)\right\}}{\exp\left\{\text{IV}(j)\right\}} \frac{\exp\left\{\tau(j)\text{IV}(j)\right\}}{\sum_m \exp\left(\tau_m \text{IV}_m\right)}$$

where $\tau(j)$ and $\text{IV}(j)$ are the dissimilarity parameter and inclusive value for the nest in which alternative j lies.

In contrast, for the nonnormalized model, we have a latent variable

$$\widetilde{V}_{i,j} = \widetilde{\alpha}_j + \mathbf{x}_{i,j}\widetilde{\boldsymbol{\beta}}_j + \mathbf{z}_i\widetilde{\boldsymbol{\gamma}}_j$$

and corresponding inclusive values

$$\widetilde{\text{IV}}_m = \ln \sum_{j \in B_m} \exp\left(\widetilde{V}_k\right) \tag{2}$$

The probability of choosing alternative j is

$$\Pr_j = \frac{\exp\left(\widetilde{V}_j\right)}{\exp\left\{\widetilde{\text{IV}}(j)\right\}} \frac{\exp\left\{\tau(j)\widetilde{\text{IV}}(j)\right\}}{\sum_m \exp\left(\tau_m \widetilde{\text{IV}}_m\right)}$$

Equations (1) and (2) represent the key difference between the RUM-consistent and nonnormalized models. By scaling the V_{ij} within each nest, the RUM-consistent model allows utilities to be compared across nests. Without the rescaling, utilities can be compared only for goods within the same nest. Moreover, adding a constant to each V_{ij} for consumer i will not affect the probabilities of the RUM-consistent model, but adding a constant to each $\widetilde{V}_{ij}$ will affect the probabilities from the nonnormalized model. Decisions based on utility maximization can depend only on utility differences and not the scale or zero point of the utility function because utility is an ordinal concept, so the nonnormalized model cannot be consistent with utility maximization.

Heiss (2002) showed that the nonnormalized model can be RUM consistent in the special case where all the variables are specified in the bottom-level equation. Then multiplying the nonnormalized coefficients by the respective dissimilarity parameters results in the RUM-consistent coefficients.

❑ Technical note

Degenerate nests occur when there is only one alternative in a branch of the tree hierarchy. The associated dissimilarity parameter of the RUM model is not defined. The inclusive-valued parameter of the nonnormalized model will be identifiable if there are alternative-specific variables specified in (1) of the model specification (the *indepvars* in the model syntax). Numerically, you can skirt the issue of nonidentifiable/undefined parameters by setting constraints on them. For the RUM model constraint, set the dissimilarity parameter to 1. See the description of `constraints()` in *Options* for details on setting constraints on the dissimilarity parameters.

Methods and formulas

nlogit, nlogitgen, and nlogittree are implemented as ado-files.

Methods and formulas are presented under the following headings:

Two-level nested logit model
Three-level nested logit model

Two-level nested logit model

Consider our two-level nested logit model for restaurant choice. We define $T = \{1, 2, 3\}$ to be the set of indices denoting the three restaurant types and $R_1 = \{1, 2\}$, $R_2 = \{3, 4, 5\}$, and $R_3 = \{6, 7\}$ to be the set of indices representing each restaurant within type $t \in T$. Let C_1 and C_2 be the random variables that represent the choices made for the first level, restaurant type, and second level, restaurant, of the hierarchy, where we observe the choices $C_1 = t, t \in T$, and $C_2 = j, j \in R_t$. Let $\mathbf{z}_t$ and $\mathbf{x}_{tj}$, for $t \in T$ and $j \in R_t$, refer to the row vectors of explanatory variables for the first-level alternatives and bottom-level alternatives for one case, respectively. We write the utilities (latent variables) as $U_{tj} = \mathbf{z}_t\boldsymbol{\alpha}_t + \mathbf{x}_{tj}\boldsymbol{\beta}_j + \epsilon_{tj} = \boldsymbol{\eta}_{tj} + \epsilon_{tj}$, where $\boldsymbol{\alpha}_t$ and $\boldsymbol{\beta}_j$ are column vectors and the ϵ_{tj} are random disturbances. When the $\mathbf{x}_{tj}$ are alternative specific, we can drop the indices from $\boldsymbol{\beta}$, where we estimate one coefficient for each alternative in R_t, $t \in T$. These variables are specified in the first equation of the `nlogit` syntax (see example 3).

When the random-utility framework is used to describe the choice behavior, the alternative that is chosen is the alternative that has the highest utility. Assume for our restaurant example that we choose restaurant type $t \in T$. For the RUM parameterization of `nlogit`, the conditional distribution of ϵ_{tj} given choice of restaurant type t is a multivariate version of Gumbel's extreme-value distribution,

$$F_{R|T}(\boldsymbol{\epsilon} \,|\, t) = \exp\left[-\left\{\sum_{m \in R_t} \exp(\epsilon_{tm}/\tau_t)\right\}^{\tau_t}\right] \tag{3}$$

where it has been shown that the ϵ_{tj}, $j \in R_t$, are exchangeable with correlation $1 - \tau_t^2$, for $\tau_t \in (0, 1]$ (Kotz and Nadarajah 2000). For example, the probability of choosing Christopher's, $j = 6$ given type $t = 3$, is

$$\begin{aligned}
\Pr(C_2 = 6 \,|\, C_1 = 3) &= \Pr\left(U_{36} - U_{37} > 0\right) \\
&= \Pr\left(\epsilon_{37} \leq \epsilon_{36} + \eta_{36} - \eta_{37}\right) \\
&= \int_{-\infty}^{\infty} \left\{ \int_{-\infty}^{\epsilon_{36}+\eta_{36}-\eta_{37}} f_{R|T}\left(\epsilon_{36}, \epsilon_{37}\right) d\epsilon_{37} \right\} d\epsilon_{36}
\end{aligned}$$

where $f = \dfrac{\partial F}{\partial \epsilon_{36} \partial \epsilon_{37}}$ is the joint density function of $\boldsymbol{\epsilon}$ given t. U_{37} is the utility of eating at Mad Cows, the other fancy ($t = 3$) restaurant. Amemiya (1985) demonstrates that this integral evaluates to the logistic function

$$\begin{aligned}
\Pr(C_2 = 6 \,|\, C_1 = 3) &= \frac{\exp(\boldsymbol{\eta}_{36}/\tau_3)}{\exp(\boldsymbol{\eta}_{36}/\tau_3) + \exp(\boldsymbol{\eta}_{37}/\tau_3)} \\
&= \frac{\exp(\mathbf{x}_{36}\boldsymbol{\beta}_6/\tau_3)}{\exp(\mathbf{x}_{36}\boldsymbol{\beta}_6/\tau_3) + \exp(\mathbf{x}_{37}\boldsymbol{\beta}_7/\tau_3)}
\end{aligned}$$

and in general

$$\Pr(C_2 = j \,|\, C_1 = t) = \frac{\exp(\mathbf{x}_{tj}\boldsymbol{\beta}_j/\tau_t)}{\sum_{m \in R_t} \exp(\mathbf{x}_{tm}\boldsymbol{\beta}_m/\tau_t)} \tag{4}$$

Letting $\tau_t = 1$ in (3) reduces to the product of independent extreme-value distributions, and (4) reduces to the multinomial logistic function.

For the logistic function in (4), we scale the linear predictors by the dissimilarity parameters. Another formulation of the conditional probability of choosing alternative $j \in R_t$ given choice $t \in T$ is the logistic function without this normalization:

$$\Pr(C_2 = j \mid C_1 = t) = \frac{\exp(\mathbf{x}_{tj}\boldsymbol{\beta}_j)}{\sum_{m\in R_t}\exp(\mathbf{x}_{tm}\boldsymbol{\beta}_m)}$$

and this is what is used in `nlogit`'s nonnormalized parameterization.

Amemiya (1985) defines the general form for the joint distribution of the ϵ's as

$$F_{T,R}(\boldsymbol{\epsilon}) = \exp\left\{-\sum_{k\in T}\theta_k\left(\sum_{m\in R_k}\exp(-\epsilon_{km}/\tau_k)\right)^{\tau_k}\right\}$$

from which the probability of choice $t, t \in T$ can be derived as

$$\Pr(C_1 = t) = \frac{\theta_t\left\{\sum_{m\in R_t}\exp(\boldsymbol{\eta}_{tm}/\tau_t)\right\}^{\tau_t}}{\sum_{k\in T}\theta_k\left\{\sum_{m\in R_k}\exp(\boldsymbol{\eta}_{km}/\tau_k)\right\}^{\tau_k}} \tag{5}$$

`nlogit` sets $\theta_t = 1$. Noting that

$$\begin{aligned}\left\{\sum_{m\in R_t}\exp(\boldsymbol{\eta}_{tm}/\tau_t)\right\}^{\tau_t} &= \left\{\sum_{m\in R_t}\exp\left(\frac{\mathbf{z}_t\boldsymbol{\alpha}_t + \mathbf{x}_{tm}\boldsymbol{\beta}_m}{\tau_t}\right)\right\}^{\tau_t}\\ &= \exp(\mathbf{z}_t\boldsymbol{\alpha}_t)\left\{\sum_{m\in R_t}\exp\left(\mathbf{x}_{tm}\boldsymbol{\beta}_m/\tau_t\right)\right\}^{\tau_t}\\ &= \exp(\mathbf{z}_t\boldsymbol{\alpha}_t + \tau_t I_t)\end{aligned}$$

we define the inclusive values I_t as

$$I_t = \ln\left\{\sum_{m\in R_t}\exp(\mathbf{x}_{tm}\boldsymbol{\beta}_m/\tau_t)\right\}$$

and we can view

$$\exp(\tau_t I_t) = \left\{\sum_{m\in R_t}\exp(x_{tm}\boldsymbol{\beta}_m)^{1/\tau_t}\right\}^{\tau_t}$$

as a weighted average of the $\exp(x_{tm}\boldsymbol{\beta}_m)$, for $m \in R_t$. For the `nlogit` RUM parameterization, we can express (5) as

$$\Pr(C_1 = t) = \frac{\exp(\mathbf{z}_t\boldsymbol{\alpha}_t + \tau_t I_t)}{\sum_{k\in T}\exp(\mathbf{z}_k\boldsymbol{\alpha}_k + \tau_k I_k)}$$

Next we define inclusive values for the nonnormalized model to be

$$\widetilde{I}_t = \ln\left\{\sum_{m\in R_t}\exp(\mathbf{x}_{tm}\boldsymbol{\beta}_m)\right\}$$

and we express $\Pr(C_1 = t)$ as

$$\Pr(C_1 = t) = \frac{\exp(\mathbf{z}_t\boldsymbol{\alpha}_t + \tau_t\widetilde{I}_t)}{\sum_{k\in T}\exp(\mathbf{z}_k\boldsymbol{\alpha}_k + \tau_k\widetilde{I}_k)} \tag{6}$$

Equation (5) is consistent with (6) only when $\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta}_j$, so in general the `nlogit` nonnormalized model is not consistent with the RUM model.

Now assume that we have N cases where we add a third subscript, i, to denote case i, $i = 1, \ldots, N$. Denote y_{itj} to be a binary variable indicating the choice made by case i so that for each i only one y_{itj} is 1 and the rest are 0 for all $t \in T$ and $j \in R_t$. The log likelihood for the two-level RUM-consistent model is

$$\begin{aligned}\log \ell &= \sum_{i=1}^{N}\sum_{k\in T}\sum_{m\in R_k} y_{ikm}\log\{\Pr(C_{i1}=i)\Pr(C_{i2}=m|C_{i1}=i)\} \\ &= \sum_{i=1}^{N}\sum_{k\in T}\sum_{m\in R_k} y_{ikm}\left[\mathbf{z}_{ik}\boldsymbol{\alpha}_k + \tau_k I_{ik} - \log\left\{\sum_{l\in T}\exp(\mathbf{z}_{il}\boldsymbol{\alpha}_l + \tau_l I_{il})\right\} + \right. \\ &\qquad \left. \mathbf{x}_{ikm}\boldsymbol{\beta}_m/\tau_k - \log\left\{\sum_{l\in R_k}\exp(\mathbf{x}_{ikl}\boldsymbol{\beta}_l/\tau_k)\right\}\right]\end{aligned}$$

The likelihood for the nonnormalized model has a similar form, replacing I with $\widetilde{I}$ and by not scaling $\mathbf{x}_{ikj}\boldsymbol{\beta}_j$ by τ_k.

Three-level nested logit model

Here we define a three-level nested logit model that can be generalized to the four-level and higher models. As before, let the integer set T be the indices for the first level of choices. Let sets S_t, $t \in T$, be mutually exclusive sets of integers representing the choices of the second level of the hierarchy. Finally, let R_j, $j \in S_t$, be the bottom-level choices. Let $U_{tjk} = \eta_{tjk} + \epsilon_{tjk}$, $k \in R_j$, and the distribution of ϵ_{tjk} be Gumbel's multivariate extreme value of the form

$$F(\boldsymbol{\epsilon}) = \exp\left(-\sum_{t\in T}\left[\sum_{j\in S_t}\left\{\sum_{k\in R_j}\exp(-\eta_{tjk}/\tau_j)\right\}^{\tau_j/\upsilon_t}\right]^{\upsilon_j}\right)$$

Let C_1, C_2, and C_3 represent the choice random variables for levels 1, 2, and the bottom, respectively. Then the set of conditional probabilities is

$$\Pr(C_3 = k \,|\, C_1 = t, C_2 = j) = \frac{\exp(\eta_{tjk}/\tau_j)}{\sum_{l\in R_j}\exp(\eta_{tjl}/\tau_j)}$$

$$\Pr(C_2 = j \,|\, C_1 = t) = \frac{\left\{\sum_{k\in R_j}\exp(\eta_{tjk}/\tau_j)\right\}^{\tau_j/\upsilon_t}}{\sum_{l\in S_t}\left\{\sum_{k\in R_l}\exp(\eta_{tlk}/\tau_l)\right\}^{\tau_l/\upsilon_t}}$$

$$\Pr(C_1 = t) = \frac{\left[\sum_{j\in S_t}\left\{\sum_{k\in R_j}\exp(\eta_{tjk}/\tau_j)\right\}^{\tau_j/\upsilon_t}\right]^{\upsilon_t}}{\sum_{l\in T}\left[\sum_{j\in S_l}\left\{\sum_{k\in R_j}\exp(\eta_{ljk}/\tau_j)\right\}^{\tau_j/\upsilon_l}\right]^{\upsilon_l}}$$

Assume that we can decompose the linear predictor as $\eta_{tjk} = \mathbf{z}_t\boldsymbol{\alpha}_t + \mathbf{u}_{tj}\boldsymbol{\gamma}_j + \mathbf{x}_{tjk}\boldsymbol{\beta}_k$. Here $\mathbf{z}_t$, $\mathbf{u}_{tj}$, and $\mathbf{x}_{tjk}$ are the row vectors of explanatory variables for the first, second, and bottom levels of the hierarchy, respectively, and $\boldsymbol{\alpha}_t$, $\boldsymbol{\gamma}_j$, and $\boldsymbol{\beta}_k$ are the corresponding column vectors of regression coefficients for $t \in T$, $j \in S_t$, and $k \in R_j$. We then can define the inclusive values for the first and second levels as

$$I_{tj} = \log \sum_{k \in R_j} \exp(\mathbf{x}_{tjk}\boldsymbol{\beta}_k/\tau_j)$$

$$J_t = \log \sum_{j \in S_t} \exp(\mathbf{u}_{tj}\boldsymbol{\gamma}_j/\upsilon_t + \frac{\tau_j}{\upsilon_t} I_{tj})$$

and rewrite the probabilities

$$\Pr(C_3 = k \,|\, C_1 = t, C_2 = j) = \frac{\exp(\mathbf{x}_{tjk}\boldsymbol{\beta}_k/\tau_j)}{\sum_{l \in R_j} \exp(\mathbf{x}_{tjl}\boldsymbol{\beta}_l/\tau_j)}$$

$$\Pr(C_2 = j \,|\, C_1 = t) = \frac{\exp(\mathbf{u}_{tj}\boldsymbol{\gamma}_j/\upsilon_t + \frac{\tau_j}{\upsilon_t} I_{tj})}{\sum_{l \in S_t} \exp(\mathbf{u}_{tl}\boldsymbol{\gamma}_l/\upsilon_t + \frac{\tau_l}{\upsilon_t} I_{tl})}$$

$$\Pr(C_1 = t) = \frac{\exp(\mathbf{z}_t\boldsymbol{\alpha}_t + \upsilon_t J_t)}{\sum_{l \in T} \exp(\mathbf{z}_l\boldsymbol{\alpha}_l + \upsilon_l J_l)}$$

We add a fourth index, i, for case and define the indicator variable y_{lijk}, $l = 1, \ldots, N$, to indicate the choice made by case i, $t \in T$, $j \in S_t$, and $k \in R_j$. The log likelihood for the `nlogit` RUM-consistent model is

$$\ell = \sum_{i=1}^{N} \sum_{t \in T} \sum_{j \in S_t} \sum_{k \in R_j} y_{itjk} \left\{ \mathbf{z}_{it}\boldsymbol{\alpha}_t + \upsilon_t J_{it} - \log\left(\sum_{m \in T} \mathbf{z}_{im}\boldsymbol{\alpha}_m + \upsilon_m J_{im} \right) + \right.$$

$$\mathbf{u}_{itj}\boldsymbol{\gamma}_j/\upsilon_t + \frac{\tau_j}{\upsilon_t} I_{itj} - \log\left(\sum_{m \in S_t} \mathbf{u}_{itm}\boldsymbol{\gamma}_m/\upsilon_t + \frac{\tau_m}{\upsilon_t} I_{itm} \right) +$$

$$\left. \mathbf{x}_{itjk}\boldsymbol{\beta}_k/\tau_k - \sum_{m \in R_t} \exp(\mathbf{x}_{itjm}\boldsymbol{\beta}_m/\tau_k) \right\}$$

and for the nonnormalized `nlogit` model the log likelihood is

$$\ell = \sum_{i=1}^{N} \sum_{t \in T} \sum_{j \in S_t} \sum_{k \in R_j} y_{itjk} \left\{ \mathbf{z}_{it}\boldsymbol{\alpha}_t + \upsilon_t J_{it} - \log\left(\sum_{m \in T} \mathbf{z}_{im}\boldsymbol{\alpha}_m + \upsilon_m J_{im} \right) + \right.$$

$$\mathbf{u}_{itj}\boldsymbol{\gamma}_j + \tau_j I_{itj} - \log\left(\sum_{m \in S_t} \mathbf{u}_{itm}\boldsymbol{\gamma}_m + \tau_m I_{itm} \right) +$$

$$\left. \mathbf{x}_{itjk}\boldsymbol{\beta}_k - \sum_{m \in R_t} \exp(\mathbf{x}_{itjm}\boldsymbol{\beta}_m) \right\}$$

Extending the model to more than three levels is straightforward, albeit notationally cumbersome.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

Title

nlogit postestimation — Postestimation tools for nlogit

Description

The following postestimation command is of special interest after `nlogit`:

Command	Description
`estat alternatives`	alternative summary statistics

For information about this command, see [R] **asmprobit postestimation**.

The following standard postestimation commands are also available:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`	likelihood-ratio test
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic hlevel(#) altwise]

predict [type] {stub*|newvarlist} [if] [in], scores
```

statistic	Description
Main	
pr	predicted probabilities of choosing the alternatives at all levels of the hierarchy or at level #, where # is specified by `hlevel(#)`; the default
xb	linear predictors for all levels of the hierarchy or at level #, where # is specified by `hlevel(#)`
condp	predicted conditional probabilities at all levels of the hierarchy or at level #, where # is specified by `hlevel(#)`
iv	inclusive values for levels 2, ..., `e(levels)` or for `hlevel(#)`

The inclusive value for the first-level alternatives is not used in estimation; therefore, it is not calculated.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr` calculates the probability of choosing each alternative at each level of the hierarchy. Use the `hlevel(#)` option to compute the alternative probabilities at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use the *stub*`*` option to have `predict` generate j variables with the prefix *stub* and numbered from 1 to j. The `pr` option is the default and if one new variable is given, the probability of the bottom-level alternatives are computed. Otherwise, probabilities for all levels are computed and the *stub*`*` option is still valid.

`xb` calculates the linear prediction for each alternative at each level. Use the `hlevel(#)` option to compute the linear predictor at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use the *stub*`*` option to have `predict` generate j variables with the prefix *stub* and numbered from 1 to j.

`condp` calculates the conditional probabilities for each alternative at each level. Use the `hlevel(#)` option to compute the conditional probabilities of the alternatives at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use the *stub*`*` option to have `predict` generate j variables with the prefix *stub* and numbered from 1 to j.

`iv` calculates the inclusive value for each alternative at each level. Use the `hlevel(#)` option to compute the inclusive value at level #. There is no inclusive value at level 1. If `hlevel(#)` is not used, $j-1$ new variables are required, where j is the number of levels, or use *stub*`*` to have `predict` generate $j-1$ variables with the prefix *stub* and numbered from 2 to j. See *Methods and formulas* in [R] **nlogit** for a definition of the inclusive values.

`hlevel(#)` calculates the prediction only for hierarchy level #.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The `xb` option always uses alternativewise deletion.

`scores` calculates the scores for each coefficient in `e(b)`. This option requires a new-variable list of length equal to the number of columns in `e(b)`. Otherwise, use the *stub*`*` option to have `predict` generate enumerated variables with prefix *stub*.

Remarks

`predict` may be used after `nlogit` to obtain the predicted values of the probabilities, the conditional probabilities, the linear predictions, and the inclusive values for each level of the nested logit model. Predicted probabilities for `nlogit` must be interpreted carefully. Probabilities are estimated for each case as a whole and not for individual observations.

▷ Example 1

Continuing with our model in example 3 of [R] **nlogit**, we refit the model and then examine a summary of the alternatives and their frequencies in the estimation sample.

Title

nlsur — Estimation of nonlinear systems of equations

Syntax

Interactive version

```
nlsur (depvar_1 = <sexp_1>) (depvar_2 = <sexp_2>) ... [if] [in] [weight] [, options]
```

Programmed substitutable expression version

```
nlsur sexp_prog : depvar_1 depvar_2 ... [varlist] [if] [in] [weight] [, options]
```

Function evaluator program version

```
nlsur func_prog @ depvar_1 depvar_2 ... [varlist] [if] [in] [weight] ,
    nequations(#) { parameters(namelist) | nparameters(#) } [options]
```

where

depvar_j is the dependent variable for equation j;

<sexp>_j is the substitutable expression for equation j;

sexp_prog is a substitutable expression program; and

func_prog is a function evaluator program.

options	Description
Model	
`fgnls`	use two-step FGNLS estimator; the default
`ifgnls`	use iterative FGNLS estimator
`nls`	use NLS estimator
`variables(`*varlist*`)`	variables in model
`initial(`*initial_values*`)`	initial values for parameters
`nequations(#)`	number of equations in model (function evaluator program version only)
* `parameters(`*namelist*`)`	parameters in model (function evaluator program version only)
* `nparameters(#)`	number of parameters in model (function evaluator program version only)
sexp_options	options for substitutable expression program
func_options	options for function evaluator program
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `gnr`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`title(`*string*`)`	display *string* as title above the table of parameter estimates
`title2(`*string*`)`	display *string* as subtitle
display_options	control column formats and line width
Optimization	
optimization_options	control the optimization process; seldom used
`eps(#)`	specify # for convergence criteria; default is `eps(1e-5)`
`ifgnlsiterate(#)`	set maximum number of FGNLS iterations
`ifgnlseps(#)`	specify # for FGNLS convergence criterion; default is `ifgnlseps(1e-10)`
`delta(#)`	specify stepsize # for computing derivatives; default is `delta(4e-7)`
`noconstants`	no equations have constant terms
`hasconstants(`*namelist*`)`	use *namelist* as constant terms
`coeflegend`	display legend instead of statistics

* You must specify `parameters(`*namelist*`)`, `nparameters(#)`, or both.

`bootstrap`, `by`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweights` are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Multiple-equation models > Nonlinear seemingly unrelated regression

Description

`nlsur` fits a system of nonlinear equations by feasible generalized nonlinear least squares (FGNLS). With the interactive version of the command, you enter the system of equations on the command line or in the dialog box by using *substitutable expressions*. If you have a system that you use regularly, you can write a *substitutable expression program* and use the second syntax to avoid having to reenter the system every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the system of equations.

When you write a substitutable expression program or a function evaluator program, the first five letters of the name must be `nlsur`. *sexp_prog* and *func_prog* refer to the name of the program without the first five letters. For example, if you wrote a function evaluator program named `nlsurregss`, you would type `nlsur regss @ ...` to estimate the parameters.

Options

Model

`fgnls` requests the two-step FGNLS estimator; this is the default.

`ifgnls` requests the iterative FGNLS estimator. For the nonlinear systems estimator, this is equivalent to maximum likelihood estimation.

`nls` requests the nonlinear least-squares (NLS) estimator.

`variables(`*varlist*`)` specifies the variables in the system. `nlsur` ignores observations for which any of these variables has missing values. If you do not specify `variables()`, `nlsur` issues an error message if the estimation sample contains any missing values.

`initial(`*initial_values*`)` specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where k is the total number of parameters in the system, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
. nlsur ..., initial(alpha 1.23 delta 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `nlsur` ignores the row and column names of the matrix.

`nequations(#)` specifies the number of equations in the system.

`parameters(`*namelist*`)` specifies the names of the parameters in the system. The names of the parameters must adhere to the naming conventions of Stata's variables; see [U] **11.3 Naming conventions**. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`nparameters(#)` specifies the number of parameters in the system. If you do not specify names with the `parameters()` options, `nlsur` names them `b1`, `b2`, ..., `b#`. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

sexp_options refer to any options allowed by your *sexp_prog*.

func_options refer to any options allowed by your *func_prog*.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(gnr)`, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

Reporting

`level(#)`; see [R] **estimation options**.

`title(`*string*`)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(`*string*`)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Optimization

optimization_options: `iterate(#)`, [`no`]`log`, `trace`. `iterate()` specifies the maximum number of iterations to use for NLS at each round of FGNLS estimation. This option is different from `ifgnlsiterate()`, which controls the maximum rounds of FGNLS estimation to use when the `ifgnls` option is specified. `log`/`nolog` specifies whether to show the iteration log, and `trace` specifies that the iteration log should include the current parameter vector.

`eps(#)` specifies the convergence criterion for successive parameter estimates and for the residual sum of squares (RSS). The default is `eps(1e-5)` (0.00001). `eps()` also specifies the convergence criterion for successive parameter estimates between rounds of iterative FGNLS estimation when `ifgnls` is specified.

`ifgnlsiterate(#)` specifies the maximum number of FGNLS iterations to perform. The default is the number set using `set maxiter` (see [R] **maximize**), which is 16,000 by default. To use this option, you must also specify the `ifgnls` option.

`ifgnlseps(#)` specifies the convergence criterion for successive estimates of the error covariance matrix during iterative FGNLS estimation. The default is `ifgnlseps(1e-10)`. To use this option, you must also specify the `ifgnls` option.

`delta(#)` specifies the relative change in a parameter, δ, to be used in computing the numeric derivatives. The derivative for parameter β_i is computed as

$$\{f_i(\mathbf{x}_i, \beta_1, \beta_2, \ldots, \beta_i + d, \beta_{i+1}, \ldots) - f_i(\mathbf{x}_i, \beta_1, \beta_2, \ldots, \beta_i, \beta_{i+1}, \ldots)\}/d$$

where $d = \delta(|\beta_i| + \delta)$. The default is `delta(4e-7)`.

`noconstants` indicates that none of the equations in the system includes constant terms. This option is generally not needed, even if there are no constant terms in the system; though in rare cases without this option, `nlsur` may claim that there is one or more constant terms even if there are none.

`hasconstants(`*namelist*`)` indicates the parameters that are to be treated as constant terms in the system of equations. The number of elements of *namelist* must equal the number of equations in

the system. The ith entry of *namelist* specifies the constant term in the ith equation. If an equation does not include a constant term, specify a period (.) instead of a parameter name. This option is seldom needed with the interactive and programmed substitutable expression versions, because in those cases `nlsur` can almost always find the constant terms automatically.

The following options are available with `nlsur` but are not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Introduction
Substitutable expression programs
Function evaluator programs

Introduction

`nlsur` fits a system of nonlinear equations by FGNLS. It can be viewed as a nonlinear variant of Zellner's seemingly unrelated regression model (Zellner 1962; Zellner and Huang 1962; Zellner 1963) and is therefore commonly called nonlinear SUR or nonlinear SURE. The model is also discussed in textbooks such as Davidson and MacKinnon (1993, 2004) and Greene (2012, 305–306). Formally, the model fit by `nlsur` is

$$\begin{aligned} y_{i1} &= f_1(\mathbf{x}_i, \beta) + u_{i1} \\ y_{i2} &= f_2(\mathbf{x}_i, \beta) + u_{i2} \\ \vdots &= \vdots \\ y_{iM} &= f_M(\mathbf{x}_i, \beta) + u_{iM} \end{aligned}$$

for $i = 1, \ldots, N$ observations and $m = 1, \ldots, M$ equations. The errors for the ith observation, $u_{i1}, u_{i2}, \ldots, u_{iM}$, may be correlated, so fitting the m equations jointly may lead to more efficient estimates. Moreover, fitting the equations jointly allows us to impose cross-equation restrictions on the parameters. Not all elements of the parameter vector β and data vector $\mathbf{x}_i$ must appear in all the equations, though each element of β must appear in at least one equation for β to be identified. For this model, iterative FGNLS estimation is equivalent to maximum likelihood estimation with multivariate normal disturbances.

The syntax you use with `nlsur` closely mirrors that used with `nl`. In particular, you use substitutable expressions with the interactive and programmed substitutable expression versions to define the functions in your system. See [R] **nl** for more information on substitutable expressions. Here we reiterate the three rules that you must follow:

1. Parameters of the model are bound in braces: `{b0}`, `{param}`, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: `{b0=1}`, `{param=3.571}`, etc. If you do not specify an initial value, that parameter is initialized to zero. The `initial()` option overrides initial values in substitutable expressions.

3. Linear combinations of variables can be included using the notation {*eqname*:*varlist*}, for example, {xb: mpg price weight}, {score: w x z}, etc. Parameters of linear combinations are initialized to zero.

▷ Example 1: Interactive version using two-step FGNLS estimator

We have data from an experiment in which two closely related types of bacteria were placed in a Petri dish, and the number of each type of bacteria were recorded every hour. We suspect a two-parameter exponential growth model can be used to model each type of bacteria, but because they shared the same dish, we want to allow for correlation in the error terms. We want to fit the system of equations

$$p_1 = \beta_1 {\beta_2}^t + u_1$$
$$p_2 = \gamma_1 {\gamma_2}^t + u_2$$

where p_1 and p_2 are the two populations and t is time, and we want to allow for nonzero correlation between u_1 and u_2. We type

```
. use http://www.stata-press.com/data/r12/petridish
. nlsur (p1 = {b1}*{b2}^t) (p2 = {g1}*{g2}^t)
(obs = 25)
Calculating NLS estimates...
Iteration 0:  Residual SS =  335.5286
Iteration 1:  Residual SS =  333.8583

/g2	1.102315	.0072183	152.71	0.000	1.088167	1.116463

The header of the output contains a summary of each equation, including the number of observations and parameters and the root mean squared error of the residuals. `nlsur` checks to see whether each equation contains a constant term, and if an equation does contain a constant term, an R^2 statistic is

presented. If an equation does not have a constant term, an uncentered R^2 is instead reported. The R^2 statistic for each equation measures the percentage of variance explained by the nonlinear function and may be useful for descriptive purposes, though it does not have the same formal interpretation in the context of FGNLS as it does with NLS estimation. As we would expect, β_2 and γ_2 are both greater than one, indicating the two bacterial populations increased in size over time.

◁

The model we fit in the next three examples is in fact linear in the parameters, so it could be fit using the `sureg` command. However, we will fit the model using `nlsur` so that we can focus on the mechanics of using the command. Moreover, using `nlsur` will obviate the need to generate several variables as well as the need to use the `constraint` command to impose parameter restrictions.

▷ Example 2: Interactive version using iterative FGNLS estimator—the translog production function

Greene (1997, sec. 15.6) discusses the transcendental logarithmic (translog) cost function and provides cost and input price data for capital, labor, energy, and materials for the U.S. economy. One way to fit the translog production function to these data is to fit the system of three equations

$$s_k = \beta_k + \delta_{kk} \ln\left(\frac{p_k}{p_m}\right) + \delta_{kl} \ln\left(\frac{p_l}{p_m}\right) + \delta_{ke} \ln\left(\frac{p_e}{p_m}\right) + u_1$$

$$s_l = \beta_l + \delta_{kl} \ln\left(\frac{p_k}{p_m}\right) + \delta_{ll} \ln\left(\frac{p_l}{p_m}\right) + \delta_{le} \ln\left(\frac{p_e}{p_m}\right) + u_2$$

$$s_e = \beta_e + \delta_{ke} \ln\left(\frac{p_k}{p_m}\right) + \delta_{le} \ln\left(\frac{p_l}{p_m}\right) + \delta_{ee} \ln\left(\frac{p_e}{p_m}\right) + u_3$$

where s_k is capital's cost share, s_l is labor's cost share, and s_e is energy's cost share; p_k, p_l, p_e, and p_m are the prices of capital, labor, energy, and materials, respectively; the u's are regression error terms; and the βs and δs are parameters to be estimated. There are three cross-equation restrictions on the parameters: δ_{kl}, δ_{ke}, and δ_{le} each appear in two equations. To fit this model by using the iterative FGNLS estimator, we type

```
. use http://www.stata-press.com/data/r12/mfgcost
. nlsur (s_k = {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke}*ln(pe/pm))
>       (s_l = {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle}*ln(pe/pm))
>       (s_e = {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee}*ln(pe/pm)),
>       ifgnls

We draw your attention to the iteration log at the top of the output. When iterative FGNLS estimation is used, the final scaled RSS will equal the product of the number of observations in the estimation sample and the number of equations; see *Methods and formulas* for details. Because the RSS is scaled by the error covariance matrix during each round of FGNLS estimation, the scaled RSS is not comparable from one FGNLS iteration to the next.

◁

❑ Technical note

You may have noticed that we mentioned having data for four factors of production, yet we fit only three share equations. Because the four shares sum to one, we must drop one of the equations to avoid having a singular error covariance matrix. The iterative FGNLS estimator is equivalent to maximum likelihood estimation, and thus it is invariant to which one of the four equations we choose to drop. The (linearly restricted) parameters of the fourth equation can be obtained using the `lincom` command. Nonlinear functions of the parameters, such as the elasticities of substitution, can be computed using `nlcom`.

❑

Substitutable expression programs

If you fit the same model repeatedly or you want to share code with colleagues, you can write a *substitutable expression program* to define your system of equations and avoid having to retype the system every time. The first five letters of the program's name must be `nlsur`, and the program must set the r-class macro `r(n_eq)` to the number of equations in your system. The first equation's substitutable expression must be returned in `r(eq_1)`, the second equation's in `r(eq_2)`, and so on. You may optionally set `r(title)` to label your output; that has the same effect as specifying the `title()` option.

▷ Example 3: Programmed substitutable expression version

We return to our translog cost function, for which a substitutable expression program is

```
program nlsurtranslog, rclass
     version 12
     syntax varlist(min=7 max=7) [if]
     tokenize ‘varlist’
     args sk sl se pk pl pe pm
     local pkpm ln(‘pk’/‘pm’)
     local plpm ln(‘pl’/‘pm’)
     local pepm ln(‘pe’/‘pm’)
     return scalar n_eq = 3
     return local eq_1 "‘sk’= {bk} + {dkk}*‘pkpm’ + {dkl}*‘plpm’ + {dke}*‘pepm’"
     return local eq_2 "‘sl’= {bl} + {dkl}*‘pkpm’ + {dll}*‘plpm’ + {dle}*‘pepm’"
     return local eq_3 "‘se’= {be} + {dke}*‘pkpm’ + {dle}*‘plpm’ + {dee}*‘pepm’"
     return local title "4-factor translog cost function"
end
```

We made our program accept seven variables, for the three dependent variables s_k, s_l, and s_e, and the four factor prices p_k, p_l, p_m, and p_e. The `tokenize` command assigns to macros `‘1’`, `‘2’`, ..., `‘7’` the seven variables stored in `‘varlist’`, and the `args` command transfers those numbered macros to macros `‘sk’`, `‘sl’`, ..., `‘pm’`. Because we knew our substitutable expressions were going to be somewhat long, we created local macros to hold the log price ratios. These are simply macros that hold strings such as `ln(pk/pm)`, not variables, and they will save us some repetitious typing when we define our substitutable expressions. Our program returns the number of equations in `r(n_eq)`, and we defined our substitutable expressions in `eq_1`, `eq_2`, and `eq_3`. We do not bind the expressions in parentheses as we do with the interactive version of `nlsur`. Finally, we put a title in `r(title)` to label our output.

Our `syntax` command also accepts an `if` clause, and that is how `nlsur` indicates the estimation sample to our program. In this application, we can safely ignore it, because our program does not compute initial values. However, had we used commands such as `summarize` or `regress` to obtain initial values, then we would need to restrict those commands to analyze only the estimation sample. In those cases, typically, you simply need to include `‘if’` with the commands you are using. For example, instead of the command

```
summarize ‘depvar’, meanonly
```

you would use

```
summarize ‘depvar’ ‘if’, meanonly
```

We can check our program by typing

```
. nlsurtranslog s_k s_l s_e pk pl pe pm

. return list

scalars:
              r(n_eq) =  3

macros:
             r(title) : "4-factor translog cost function"
              r(eq_3) : "s_e= {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee.."
              r(eq_2) : "s_l= {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle.."
              r(eq_1) : "s_k= {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke.."
```

Now that we know that our program works, we fit our model by typing

```
. nlsur translog: s_k s_l s_e pk pl pe pm, ifgnls
(obs = 25)

Because we set `r(title)` in our substitutable expression program, the coefficient table has a title attached to it. The estimates are identical to those we obtained in example 2.

◁

❑ Technical note

nlsur accepts frequency and analytic weights as well as pweights (sampling weights) and iweights (importance weights). You do not need to modify your substitutable expressions in any way to perform weighted estimation, though you must make two changes to your substitutable expression program. The general outline of a *sexp_prog* program is

```
program nlsur name, rclass
    version 12
    syntax varlist [fw aw pw iw] [if]
    // Obtain initial values incorporating weights.  For example,
    summarize varname ['weight''exp'] 'if'
    ...
    // Return n_eqn and substitutable expressions
    return scalar n_eq = #
    return local eq_1 = ...
    ...
end
```

First, we wrote the syntax statement to accept a weight expression. Here we allow all four types of weights, but if you know that your estimator is valid, say, for only frequency weights, then you should modify the syntax line to accept only fweights. Second, if your program computes starting values, then any commands you use must incorporate the weights passed to the program; you do that by including ['weight''exp'] when calling those commands.

❑

Function evaluator programs

Although substitutable expressions are extremely flexible, there are some problems for which the nonlinear system cannot be defined using them. You can use the function evaluator program version of nlsur in these cases. We present two examples, a simple one to illustrate the mechanics of function evaluator programs and a more complicated one to illustrate the power of nlsur.

▷ Example 4: Function evaluator program version

Here we write a function evaluator program to fit the translog cost function used in examples 2 and 3. The function evaluator program is

```
program nlsurtranslog2
        version 12
        syntax varlist(min=7 max=7) [if], at(name)
        tokenize `varlist'
        args sk sl se pk pl pe pm
        tempname bk dkk dkl dke bl dll dle be dee
        scalar `bk'  = `at'[1,1]
        scalar `dkk' = `at'[1,2]
        scalar `dkl' = `at'[1,3]
        scalar `dke' = `at'[1,4]
        scalar `bl'  = `at'[1,5]
        scalar `dll' = `at'[1,6]
        scalar `dle' = `at'[1,7]
        scalar `be'  = `at'[1,8]
        scalar `dee' = `at'[1,9]
        local pkpm ln(`pk'/`pm')
        local plpm ln(`pl'/`pm')
        local pepm ln(`pe'/`pm')
        quietly {
                replace `sk' = `bk' + `dkk'*`pkpm' + `dkl'*`plpm' +    ///
                                      `dke'*`pepm' `if'
                replace `sl' = `bl' + `dkl'*`pkpm' + `dll'*`plpm' +    ///
                                      `dle'*`pepm' `if'
                replace `se' = `be' + `dke'*`pkpm' + `dle'*`plpm' +    ///
                                      `dee'*`pepm' `if'
        }
end
```

Unlike the substitutable expression program we wrote in example 3, `nlsurtranslog2` is not declared as r-class because we will not be returning any saved results. We are again expecting seven variables: three shares and four factor prices, and `nlsur` will again mark the estimation sample with an `if` expression.

Our function evaluator program also accepts an option named `at()`, which will receive a parameter vector at which we are to evaluate the system of equations. All function evaluator programs must accept this option. Our model has nine parameters to estimate, and we created nine temporary scalars to hold the elements of the `` `at' `` matrix.

Because our model has three equations, the first three variables passed to our program are the dependent variables that we are to fill in with the function values. We replaced only the observations in our estimation sample by including the `` `if' `` qualifier in the `replace` statements. Here we could have ignored the `` `if' `` qualifier because `nlsur` will skip over observations not in the estimation sample and we did not perform any computations requiring knowledge of the estimation sample. However, including the `` `if' `` is good practice and may result in a slight speed improvement if the functions of your model are complicated and the estimation sample is much smaller than the dataset in memory.

We could have avoided creating temporary scalars to hold our individual parameters by writing the `replace` statements as, for example,

```
replace `sk' = `at'[1,1] + `at'[1,2]*`pkpm' + `at'[1,3]*`plpm' + `at'[1,4]*`pepm' `if'
```

You can use whichever method you find more appealing, though giving the parameters descriptive names reduces the chance for mistakes and makes debugging easier.

To fit our model by using the function evaluator program version of `nlsur`, we type

```
. nlsur translog2 @ s_k s_l s_e pk pl pe pm, ifgnls nequations(3)
>        parameters(bk dkk dkl dke bl dll dle be dee)
>        hasconstants(bk bl be)

When we use the function evaluator program version, `nlsur` requires us to specify the number of equations in `nequations()`, and it requires us to either specify names for each of our parameters or the number of parameters in the model. Here we used the `parameters()` option to name our parameters; the order in which we specified them in this option is the same as the order in which we extracted them from the `'at'` matrix in our program. Had we instead specified `nparameters(9)`, our parameters would have been labeled `/b1`, `/b2`, ..., `/b9` in the output.

`nlsur` has no way of telling how many parameters appear in each equation, so the `Parms` column in the header contains missing values. Moreover, the function evaluator program version of `nlsur` does not attempt to identify constant terms, so we used the `hasconstant` option to tell `nlsur` which parameter in each equation is a constant term.

The estimates are identical to those we obtained in examples 2 and 3.

◁

❑ Technical note

As with substitutable expression programs, if you intend to do weighted estimation with a function evaluator program, you must modify your *func_prog* program's `syntax` statement to accept weights. Moreover, if you use any statistical commands when computing your nonlinear functions, then you must include the weight expression with those commands.

❑

▷ Example 5: Fitting the basic AIDS model using nlsur

Poi (2002) showed how to fit a quadratic almost ideal demand system (AIDS) by using the `ml` command. Here we show how to fit the basic AIDS model by using `nlsur`. Poi (2008) shows how to fit the quadratic AIDS model using `nlsur`. The dataset `food.dta` contains household expenditures, expenditure shares, and log prices for four broad food groups. For a four-good demand system, we need to fit the following system of three equations:

$$w_1 = \alpha_1 + \gamma_{11}\ln p_1 + \gamma_{12}\ln p_2 + \gamma_{13}\ln p_3 + \beta_1 \ln\left\{\frac{m}{P(\mathbf{p})}\right\} + u_1$$
$$w_2 = \alpha_2 + \gamma_{12}\ln p_1 + \gamma_{22}\ln p_2 + \gamma_{23}\ln p_3 + \beta_2 \ln\left\{\frac{m}{P(\mathbf{p})}\right\} + u_2$$
$$w_3 = \alpha_3 + \gamma_{13}\ln p_1 + \gamma_{23}\ln p_2 + \gamma_{33}\ln p_3 + \beta_3 \ln\left\{\frac{m}{P(\mathbf{p})}\right\} + u_3$$

where w_k denotes a household's fraction of expenditures on good k, $\ln p_k$ denotes the logarithm of the price paid for good k, m denotes a household's total expenditure on all four goods, the u's are regression error terms, and

$$\ln P(\mathbf{p}) = \alpha_0 + \sum_{i=1}^{4}\alpha_i \ln p_i + \frac{1}{2}\sum_{i=1}^{4}\sum_{j=1}^{4}\gamma_{ij}\ln p_i \ln p_j$$

The parameters for the fourth good's share equation can be recovered from the following constraints that are imposed by economic theory:

$$\sum_{i=1}^{4}\alpha_i = 1 \qquad \sum_{i=1}^{4}\beta_i = 0 \qquad \gamma_{ij} = \gamma_{ji} \qquad \text{and} \qquad \sum_{i=1}^{4}\gamma_{ij} = 0 \ \text{ for all } j$$

Our model has a total of 12 unrestricted parameters. We will not estimate α_0 directly. Instead, we will set it equal to 5 as was done in Poi (2002); see Deaton and Muellbauer (1980) for a discussion of why treating α_0 as fixed is acceptable.

Our function evaluator program is

```
program nlsuraids
        version 12
        syntax varlist(min=8 max=8) if, at(name)

                replace `w2' = `a2' + `g21'*`lnp1' + `g22'*`lnp2' + ///
                                      `g23'*`lnp3' + `g24'*`lnp4' + ///
                                      `b2'*(`lnm' - `lnpindex')
                replace `w3' = `a3' + `g31'*`lnp1' + `g32'*`lnp2' + ///
                                      `g33'*`lnp3' + `g34'*`lnp4' + ///
                                      `b3'*(`lnm' - `lnpindex')
        }
end
```

The `syntax` statement accepts eight variables: three expenditure share variables, all four log-price variables, and a variable for log expenditures ($\ln m$). Most of the code simply extracts the parameters

from the 'at' matrix. Although we are estimating only 12 parameters, to calculate the price index term and the expenditure share equations, we need the restricted parameters as well. Notice how we impose the constraints on the parameters. We then created a temporary variable to hold $\ln P(\mathbf{p})$, and we filled the three dependent variables with the predicted expenditure shares.

To fit our model, we type

```
. use http://www.stata-press.com/data/r12/food

To get the restricted parameters for the fourth share equation, we can use `lincom`. For example, to obtain α_4, we type

```
. lincom 1 - [a1]_cons - [a2]_cons - [a3]_cons
 ( 1) - [a1]_cons - [a2]_cons - [a3]_cons = -1
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
(1)	.3083643	.0052611	58.61	0.000	.2980528	.3186758

For more information on `lincom`, see [R] **lincom**.

Saved results

`nlsur` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(k)`	number of parameters
`e(k_#)`	number of parameters for equation #
`e(k_eq)`	number of equation names in `e(b)`
`e(k_eq_model)`	number of equations in overall model test
`e(n_eq)`	number of equations
`e(mss_#)`	model sum of squares for equation #
`e(rss_#)`	RSS for equation #
`e(rmse_#)`	root mean squared error for equation #
`e(r2_#)`	R^2 for equation #
`e(ll)`	Gaussian log likelihood (`iflgs` version only)
`e(N_clust)`	number of clusters
`e(rank)`	rank of `e(V)`
`e(converge)`	`1` if converged, `0` otherwise

Macros

`e(cmd)`	`nlsur`
`e(cmdline)`	command as typed
`e(method)`	`fgnls`, `ifgnls`, or `nls`
`e(depvar)`	names of dependent variables
`e(depvar_#)`	dependent variable for equation #
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(title_2)`	secondary title in estimation output
`e(clustvar)`	name of cluster variable
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used in label Std. Err.
`e(type)`	`1` = interactively entered expression `2` = substitutable expression program `3` = function evaluator program
`e(sexpprog)`	substitutable expression program
`e(sexp_#)`	substitutable expression for equation #
`e(params)`	names of all parameters
`e(params_#)`	parameters in equation #
`e(funcprog)`	function evaluator program
`e(rhs)`	contents of `variables()`
`e(constants)`	identifies constant terms
`e(properties)`	`b V`
`e(predict)`	program used to implement `predict`

Matrices

`e(b)`	coefficient vector
`e(init)`	initial values vector
`e(Sigma)`	error covariance matrix ($\widehat{\mathbf{\Sigma}}$)
`e(V)`	variance–covariance matrix of the estimators

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`nlsur` is implemented as an ado-file.

Write the system of equations for the ith observation as

$$\mathbf{y}_i = \mathbf{f}(\mathbf{x}_i, \beta) + \mathbf{u}_i \tag{1}$$

where $\mathbf{y}_i$ and $\mathbf{u}_i$ are $1 \times M$ vectors, for $i = 1, \ldots, N$; $\mathbf{f}$ is a function that returns a $1 \times M$ vector; $\mathbf{x}_i$ represents all the exogenous variables in the system; and β is a $1 \times k$ vector of parameters. The generalized nonlinear least-squares system estimator is defined as

$$\widehat{\beta} \equiv \text{argmin}_\beta \sum_{i=1}^{N} \{\mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \beta)\} \, \mathbf{\Sigma}^{-1} \, \{\mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \beta)\}'$$

where $\mathbf{\Sigma} = E(\mathbf{u}_i' \mathbf{u}_i)$ is an $M \times M$ positive-definite weight matrix. Let $\mathbf{T}$ be the Cholesky decomposition of $\mathbf{\Sigma}^{-1}$; that is, $\mathbf{T}\mathbf{T}' = \mathbf{\Sigma}^{-1}$. Postmultiply (1) by $\mathbf{T}$:

$$\mathbf{y}_i \mathbf{T} = \mathbf{f}(\mathbf{x}_i, \beta)\mathbf{T} + \mathbf{u}_i \mathbf{T} \tag{2}$$

Because $E(\mathbf{T}' \mathbf{u}_i' \mathbf{u}_i \mathbf{T}) = \mathbf{I}$, we can "stack" the columns of (2) and write

$$\begin{aligned}
\mathbf{y}_1\mathbf{T}_1 &= \mathbf{f}(\mathbf{x}_1, \beta)\mathbf{T}_1 + \widetilde{u}_{11} \\
\mathbf{y}_1\mathbf{T}_2 &= \mathbf{f}(\mathbf{x}_1, \beta)\mathbf{T}_2 + \widetilde{u}_{12} \\
&\vdots = \vdots \\
\mathbf{y}_1\mathbf{T}_M &= \mathbf{f}(\mathbf{x}_1, \beta)\mathbf{T}_M + \widetilde{u}_{1M} \\
&\vdots = \vdots \\
\mathbf{y}_N\mathbf{T}_1 &= \mathbf{f}(\mathbf{x}_N, \beta)\mathbf{T}_1 + \widetilde{u}_{N1} \\
\mathbf{y}_N\mathbf{T}_2 &= \mathbf{f}(\mathbf{x}_N, \beta)\mathbf{T}_2 + \widetilde{u}_{N2} \\
&\vdots = \vdots \\
\mathbf{y}_N\mathbf{T}_M &= \mathbf{f}(\mathbf{x}_N, \beta)\mathbf{T}_M + \widetilde{u}_{NM}
\end{aligned} \tag{3}$$

where $\mathbf{T}_j$ denotes the jth column of $\mathbf{T}$. By construction, all $\widetilde{u}_{ij}$ are independently distributed with unit variance. As a result, by transforming the model in (1) to that shown in (3), we have reduced the multivariate generalized nonlinear least-squares system estimator to a univariate nonlinear least-squares problem; and the same parameter estimation technique used by `nl` can be used here. See [R] **nl** for the details. Moreover, because the $\widetilde{u}_{ij}$ all have variance 1, the final scaled RSS reported by `nlsur` is equal to NM.

To make the estimator feasible, we require an estimate $\widehat{\mathbf{\Sigma}}$ of $\mathbf{\Sigma}$. `nlsur` first sets $\widehat{\mathbf{\Sigma}} = \mathbf{I}$. Although not efficient, the resulting estimate, $\widehat{\beta}_{\rm NLS}$, is consistent. If the `nls` option is specified, estimation is complete. Otherwise, the residuals

$$\widehat{\mathbf{u}}_i = \mathbf{y}_i - \mathbf{f}(\mathbf{x}_i, \widehat{\beta}_{\rm NLS})$$

are calculated and used to compute

$$\widehat{\mathbf{\Sigma}} = \frac{1}{N}\sum_{i=1}^{N} \widehat{\mathbf{u}}_i' \widehat{\mathbf{u}}_i$$

With $\widehat{\mathbf{\Sigma}}$ in hand, a new estimate $\widehat{\beta}$ is then obtained.

If the `ifgnls` option is specified, the new $\widehat{\beta}$ is used to recompute the residuals and obtain a new estimate of $\widehat{\mathbf{\Sigma}}$, from which $\widehat{\beta}$ can then be reestimated. Iterations stop when the relative change in $\widehat{\beta}$ is less than `eps()`, the relative change in $\widehat{\mathbf{\Sigma}}$ is less than `ifgnlseps()`, or if `ifgnlsiterate()` iterations have been performed.

If the `vce(robust)` and `vce(cluster` *clustvar*`)` options were not specified, then

$$V(\widehat{\beta}) = \left(\sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i\right)^{-1}$$

where the $M \times k$ matrix $\mathbf{X}_i$ has typical element X_{ist}, the derivative of the sth element of $\mathbf{f}$ with respect to the tth element of β, evaluated at $\mathbf{x}_i$ and $\widehat{\beta}$. As a practical matter, once the model is written in the form of (3), the variance–covariance matrix can be calculated via a Gauss–Newton regression; see Davidson and MacKinnon (1993, chap. 6).

If `robust` is specified, then

$$V_R(\widehat{\beta}) = \left(\sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i\right)^{-1} \sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \widehat{\mathbf{u}}_i' \widehat{\mathbf{u}}_i \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i \left(\sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i\right)^{-1}$$

The cluster–robust variance matrix is

$$V_C(\widehat{\beta}) = \left(\sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i\right)^{-1} \sum_{c=1}^{N_C} \mathbf{w}_c' \mathbf{w}_c \left(\sum_{i=1}^{N} \mathbf{X}_i' \widehat{\mathbf{\Sigma}}^{-1} \mathbf{X}_i\right)^{-1}$$

where N_C is the number of clusters and

$$\mathbf{w}_c = \sum_{j \in C_k} \mathbf{X}_j' \widehat{\mathbf{\Sigma}}^{-1} \widehat{\mathbf{u}}_j'$$

with C_k denoting the set of observations in the kth cluster. In evaluating these formulas, we use the value of $\widehat{\mathbf{\Sigma}}$ used in calculating the final estimate of $\widehat{\beta}$. That is, we do not recalculate $\widehat{\mathbf{\Sigma}}$ after we obtain the final value of $\widehat{\beta}$.

The RSS for the jth equation, RSS_j, is

$$\text{RSS}_j = \sum_{i=1}^{N} (\widehat{y}_{ij} - y_{ij})^2$$

where $\widehat{y}_{ij}$ is the predicted value of the ith observation on the jth dependent variable; the total sum of squares (TSS) for the jth equation, TSS_j, is

$$\text{TSS}_j = \sum_{i=1}^{N} (y_{ij} - \bar{y}_j)^2$$

if there is a constant term in the jth equation, where $\bar{y}_j$ is the sample mean of the jth dependent variable, and

$$\text{TSS}_j = \sum_{i=1}^{N} y_{ij}^2$$

if there is no constant term in the jth equation; and the model sum of squares (MSS) for the jth equation, MSS_j, is $\text{TSS}_j - \text{RSS}_j$.

The R^2 for the jth equation is $\text{MSS}_j/\text{TSS}_j$. If an equation does not have a constant term, then the reported R^2 for that equation is "uncentered" and based on the latter definition of TSS_j.

Under the assumption that the $\mathbf{u}_i$ are independent and identically distributed $N(\mathbf{0}, \widehat{\mathbf{\Sigma}})$, the log likelihood for the model is

$$\ln L = -\frac{MN}{2}\{1 + \ln(2\pi)\} - \frac{N}{2}\ln\left|\widehat{\mathbf{\Sigma}}\right|$$

The log likelihood is reported only when the `ifgnls` option is specified.

Title

nlsur postestimation — Postestimation tools for nlsur

Description

The following postestimation commands are available after `nlsur`:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`lrtest`	likelihood-ratio test
`margins`[1]	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] You must specify the `variables()` option with `nlsur`.

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`,` `equation(#`*eqno*`)` `yhat` `residuals`]

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`equation(#`*eqno*`)` specifies to which equation you are referring. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. If you do not specify `equation()`, results are the same as if you had specified `equation(#1)`.

`yhat`, the default, calculates the fitted values for the specified equation.

`residuals` calculates the residuals for the specified equation.

Remarks

▷ Example 1

In example 2 of [R] **nlsur**, we fit a four-factor translog cost function to data for the U.S. economy. The own-price elasticity for a factor measures the percentage change in its usage as a result of a 1% increase in the factor's price, assuming that output is held constant. For the translog production function, the own-price factor elasticities are

$$\eta_i = \frac{\delta_{ii} + s_i(s_i - 1)}{s_i}$$

Here we compute the elasticity for capital at the sample mean of capital's factor share. First, we use `summarize` to get the mean of `s_k` and store that value in a scalar:

```
. summarize s_k
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
         s_k |         25    .053488    .0044795      .04602      .06185
. scalar kmean = r(mean)
```

Now we can use `nlcom` to calculate the elasticity:

```
. nlcom (([dkk]_cons + kmean*(kmean-1)) / kmean)
       _nl_1:  ([dkk]_cons + kmean*(kmean-1)) / kmean
------------------------------------------------------------------------------
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       _nl_1 |  -.3952986   .1083535    -3.65   0.000    -.6076676   -.1829295
------------------------------------------------------------------------------
```

If the price of capital increases by 1%, its usage will decrease by about 0.4%. To maintain its current level of output, a firm would increase its usage of other inputs to compensate for the lower capital usage. The standard error reported by `nlcom` reflects the sampling variance of the estimated parameter $\widehat{\delta_{kk}}$, but `nlcom` treats the sample mean of `s_k` as a fixed parameter that does not contribute to the sampling variance of the estimated elasticity.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

[U] **20 Estimation and postestimation commands**

Title

nptrend — Test for trend across ordered groups

Syntax

```
nptrend varname [if] [in] , by(groupvar) [nodetail score(scorevar)]
```

Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Trend test across ordered groups

Description

`nptrend` performs a nonparametric test for trend across ordered groups.

Options

Main

`by(`*groupvar*`)` is required; it specifies the group on which the data are to be ordered.

`nodetail` suppresses the listing of group rank sums.

`score(`*scorevar*`)` defines scores for groups. When it is not specified, the values of *groupvar* are used for the scores.

Remarks

`nptrend` performs the nonparametric test for trend across ordered groups developed by Cuzick (1985), which is an extension of the Wilcoxon rank-sum test (see [R] **ranksum**). A correction for ties is incorporated into the test. `nptrend` is a useful adjunct to the Kruskal–Wallis test; see [R] **kwallis**.

If your data are not grouped, you can test for trend with the `signtest` and `spearman` commands; see [R] **signrank** and [R] **spearman**. With `signtest`, you can perform the Cox and Stuart test, a sign test applied to differences between equally spaced observations of *varname*. With `spearman`, you can perform the Daniels test, a test of zero Spearman correlation between *varname* and a time index. See Conover (1999, 169–175, 323) for a discussion of these tests and their asymptotic relative efficiency.

▷ Example 1

The following data (Altman 1991, 217) show ocular exposure to ultraviolet radiation for 32 pairs of sunglasses classified into three groups according to the amount of visible light transmitted.

Group	Transmission of visible light	Ocular exposure to ultraviolet radiation
1	< 25%	1.4 1.4 1.4 1.6 2.3 2.3
2	25 to 35%	0.9 1.0 1.1 1.1 1.2 1.2 1.5 1.9 2.2 2.6 2.6 2.6 2.8 2.8 3.2 3.5 4.3 5.1
3	> 35%	0.8 1.7 1.7 1.7 3.4 7.1 8.9 13.5

Entering these data into Stata, we have

```
. use http://www.stata-press.com/data/r12/sg
. list, sep(6)
```

	group	exposure
1.	1	1.4
2.	1	1.4
3.	1	1.4
4.	1	1.6
5.	1	2.3
6.	1	2.3
7.	2	.9
	(*output omitted*)	
31.	3	8.9
32.	3	13.5

We use `nptrend` to test for a trend of (increasing) exposure across the three groups by typing

```
. nptrend exposure, by(group)
    group     score       obs      sum of ranks
        1         1         6            76
        2         2        18           290
        3         3         8           162

         z  =  1.52
Prob > |z| = 0.129
```

When the groups are given any equally spaced scores (such as -1, 0, 1), we will obtain the same answer as above. To illustrate the effect of changing scores, an analysis of these data with scores 1, 2, and 5 (admittedly not sensible here) produces

```
. gen mysc = cond(group==3,5,group)
. nptrend exposure, by(group) score(mysc)
    group     score       obs      sum of ranks
        1         1         6            76
        2         2        18           290
        3         5         8           162

         z  =  1.46
Prob > |z| = 0.143
```

This example suggests that the analysis is not all that sensitive to the scores chosen.

◁

❑ Technical note

The grouping variable may be either a string variable or a numeric variable. If it is a string variable and no score variable is specified, the natural numbers 1, 2, 3, ... are assigned to the groups in the sort order of the string variable. This may not always be what you expect. For example, the sort order of the strings “one”, “two”, “three” is “one”, “three”, “two”.

❑

Saved results

nptrend saves the following in r():

Scalars

r(N)	number of observations	r(z)	z statistic
r(p)	two-sided p-value	r(T)	test statistic

Methods and formulas

nptrend is implemented as an ado-file.

nptrend is based on a method in Cuzick (1985). The following description of the statistic is from Altman (1991, 215–217). We have k groups of sample sizes n_i ($i = 1, \ldots, k$). The groups are given scores, l_i, which reflect their ordering, such as 1, 2, and 3. The scores do not have to be equally spaced, but they usually are. $N = \sum n_i$ observations are ranked from 1 to N, and the sums of the ranks in each group, R_i, are obtained. L, the weighted sum of all the group scores, is

$$L = \sum_{i=1}^{k} l_i n_i$$

The statistic T is calculated as

$$T = \sum_{i=1}^{k} l_i R_i$$

Under the null hypothesis, the expected value of T is $E(T) = 0.5(N+1)L$, and its standard error is

$$\mathrm{se}(T) = \sqrt{\frac{N+1}{12}\left(N\sum_{i=1}^{k} l_i^2 n_i - L^2\right)}$$

so that the test statistic, z, is given by $z = \{T - E(T)\}/\mathrm{se}(T)$, which has an approximately standard normal distribution when the null hypothesis of no trend is true.

The correction for ties affects the standard error of T. Let $\widetilde{N}$ be the number of unique values of the variable being tested ($\widetilde{N} \leq N$), and let t_j be the number of times the jth unique value of the variable appears in the data. Define

$$a = \frac{\sum_{j=1}^{\widetilde{N}} t_j(t_j^2 - 1)}{N(N^2 - 1)}$$

The corrected standard error of T is $\widetilde{\mathrm{se}}(T) = \sqrt{1-a}\ \mathrm{se}(T)$.

Acknowledgments

nptrend was written by K. A. Stepniewska and D. G. Altman (1992) of the Cancer Research UK.

Title

ologit — Ordered logistic regression

Syntax

`ologit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *options*]

options	Description
Model	
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`or`	report odds ratios
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Ordinal outcomes > Ordered logistic regression

Description

`ologit` fits ordered logit models of ordinal variable *depvar* on the independent variables *indepvars*. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to "higher" outcomes.

See [R] **logistic** for a list of related estimation commands.

Options

Model

`offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`or` reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The following option is available with `ologit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Ordered logit models are used to estimate relationships between an ordinal dependent variable and a set of independent variables. An *ordinal* variable is a variable that is categorical and ordered, for instance, "poor", "good", and "excellent", which might indicate a person's current health status or the repair record of a car. If there are only two outcomes, see [R] **logistic**, [R] **logit**, and [R] **probit**. This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [R] **mlogit**. This entry is concerned only with models in which the outcomes can be ordered.

In ordered logit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome i corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

u_j is assumed to be logistically distributed in ordered logit. In either case, we estimate the coefficients β_1, β_2, ..., β_k together with the cutpoints κ_1, κ_2, ..., κ_{k-1}, where k is the number of possible outcomes. κ_0 is taken as $-\infty$, and κ_k is taken as $+\infty$. All of this is a direct generalization of the ordinary two-outcome logit model.

▷ Example 1

We wish to analyze the 1977 repair records of 66 foreign and domestic cars. The data are a variation of the automobile dataset described in [U] **1.2.2 Example datasets**. The 1977 repair records, like those in 1978, take on values "Poor", "Fair", "Average", "Good", and "Excellent". Here is a cross-tabulation of the data:

```
. use http://www.stata-press.com/data/r12/fullauto
(Automobile Models)
. tabulate rep77 foreign, chi2
```

Repair Record 1977	Foreign: Domestic	Foreign	Total
Poor	2	1	3
Fair	10	1	11
Average	20	7	27
Good	13	7	20
Excellent	0	5	5
Total	45	21	66

Pearson chi2(4) = 13.8619 Pr = 0.008

Although it appears that `foreign` takes on the values "`Domestic`" and "`Foreign`", it is actually a numeric variable taking on the values 0 and 1. Similarly, `rep77` takes on the values 1, 2, 3, 4, and 5, corresponding to "`Poor`", "`Fair`", and so on. The more meaningful words appear because we have attached value labels to the data; see [U] **12.6.3 Value labels**.

Because the chi-squared value is significant, we could claim that there is a relationship between `foreign` and `rep77`. Literally, however, we can only claim that the distributions are different; the chi-squared test is not directional. One way to model these data is to model the categorization that took place when the data were created. Cars have a true frequency of repair, which we will assume is given by $S_j = \beta\,\texttt{foreign}_j + u_j$, and a car is categorized as "poor" if $S_j \leq \kappa_0$, as "fair" if $\kappa_0 < S_j \leq \kappa_1$, and so on:

```
. ologit rep77 foreign
Iteration 0:   log likelihood = -89.895098
Iteration 1:   log likelihood = -85.951765
Iteration 2:   log likelihood = -85.908227
Iteration 3:   log likelihood = -85.908161
Iteration 4:   log likelihood = -85.908161
Ordered logistic regression                     Number of obs   =         66
                                                LR chi2(1)      =       7.97
                                                Prob > chi2     =     0.0047
Log likelihood = -85.908161                     Pseudo R2       =     0.0444
```

rep77	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
foreign	1.455878	.5308951	2.74	0.006	.4153425	2.496413
/cut1	-2.765562	.5988208			-3.939229	-1.591895
/cut2	-.9963603	.3217706			-1.627019	-.3657016
/cut3	.9426153	.3136398			.3278925	1.557338
/cut4	3.123351	.5423257			2.060412	4.18629

Our model is $S_j = 1.46\,\texttt{foreign}_j + u_j$; the expected value for foreign cars is 1.46 and, for domestic cars, 0; foreign cars have better repair records.

The estimated cutpoints tell us how to interpret the score. For a foreign car, the probability of a poor record is the probability that $1.46 + u_j \leq -2.77$, or equivalently, $u_j \leq -4.23$. Making this calculation requires familiarity with the logistic distribution: the probability is $1/(1+e^{4.23}) = 0.014$. On the other hand, for domestic cars, the probability of a poor record is the probability $u_j \leq -2.77$, which is 0.059.

This, it seems to us, is a far more reasonable prediction than we would have made based on the table alone. The table showed that 2 of 45 domestic cars had poor records, whereas 1 of 21 foreign cars had poor records—corresponding to probabilities $2/45 = 0.044$ and $1/21 = 0.048$. The predictions from our model imposed a smoothness assumption—foreign cars should not, overall, have better repair records without the difference revealing itself in each category. In our data, the fractions of foreign and domestic cars in the poor category are virtually identical only because of the randomness associated with small samples.

Thus if we were asked to predict the true fractions of foreign and domestic cars that would be classified in the various categories, we would choose the numbers implied by the ordered logit model:

	tabulate		logit	
	Domestic	Foreign	Domestic	Foreign
Poor	0.044	0.048	0.059	0.014
Fair	0.222	0.048	0.210	0.065
Average	0.444	0.333	0.450	0.295
Good	0.289	0.333	0.238	0.467
Excellent	0.000	0.238	0.043	0.159

See [R] **ologit postestimation** for a more complete explanation of how to generate predictions from an ordered logit model.

◁

❑ Technical note

Here ordered logit provides an alternative to ordinary two-outcome logistic models with an arbitrary dichotomization, which might otherwise have been tempting. We could, for instance, have summarized these data by converting the five-outcome `rep77` variable to a two-outcome variable, combining cars in the average, fair, and poor categories to make one outcome and combining cars in the good and excellent categories to make the second.

Another even less appealing alternative would have been to use ordinary regression, arbitrarily labeling "excellent" as 5, "good" as 4, and so on. The problem is that with different but equally valid labelings (say, 10 for "excellent"), we would obtain different estimates. We would have no way of choosing one metric over another. That assertion is not, however, true of `ologit`. The actual values used to label the categories make no difference other than through the order they imply.

In fact, our labeling was 5 for "excellent", 4 for "good", and so on. The words "excellent" and "good" appear in our output because we attached a value label to the variables; see [U] **12.6.3 Value labels**. If we were to now go back and type `replace rep77=10 if rep77==5`, changing all the 5s to 10s, we would still obtain the same results when we refit our model.

❑

▷ Example 2

In the example above, we used ordered logit as a way to model a table. We are not, however, limited to including only one explanatory variable or to including only categorical variables. We can explore the relationship of `rep77` with any of the variables in our data. We might, for instance, model `rep77` not only in terms of the origin of manufacture, but also including `length` (a proxy for size) and `mpg`:

```
. ologit rep77 foreign length mpg
Iteration 0:   log likelihood = -89.895098
Iteration 1:   log likelihood = -78.775147
Iteration 2:   log likelihood = -78.254294
Iteration 3:   log likelihood = -78.250719
Iteration 4:   log likelihood = -78.250719
Ordered logistic regression                     Number of obs   =         66
                                                LR chi2(3)      =      23.29
                                                Prob > chi2     =     0.0000
Log likelihood = -78.250719                     Pseudo R2       =     0.1295
```

rep77	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
foreign	2.896807	.7906411	3.66	0.000	1.347179	4.446435
length	.0828275	.02272	3.65	0.000	.0382972	.1273579
mpg	.2307677	.0704548	3.28	0.001	.0926788	.3688566
/cut1	17.92748	5.551191			7.047344	28.80761
/cut2	19.86506	5.59648			8.896161	30.83396
/cut3	22.10331	5.708936			10.914	33.29262
/cut4	24.69213	5.890754			13.14647	36.2378

`foreign` still plays a role—and an even larger role than previously. We find that larger cars tend to have better repair records, as do cars with better mileage ratings.

◁

Saved results

ologit saves the following in e():

Scalars

e(N)	number of observations
e(N_cd)	number of completely determined observations
e(k_cat)	number of categories
e(k)	number of parameters
e(k_aux)	number of auxiliary parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(r2_p)	pseudo-R-squared
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance of model test
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	ologit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(cat)	category values
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

`ologit` is implemented as an ado-file.

See Long and Freese (2006, chap. 5) for a discussion of models for ordinal outcomes and examples that use Stata. Cameron and Trivedi (2005, chap. 15) describe multinomial models, including the model fit by `ologit`. When you have a qualitative dependent variable, several estimation procedures are available. A popular choice is multinomial logistic regression (see [R] **mlogit**), but if you use this procedure when the response variable is ordinal, you are discarding information because multinomial logit ignores the ordered aspect of the outcome. Ordered logit and probit models provide a means to exploit the ordering information.

There is more than one "ordered logit" model. The model fit by `ologit`, which we will call the ordered logit model, is also known as the proportional odds model. Another popular choice, not fit by `ologit`, is known as the stereotype model; see [R] **slogit**. All ordered logit models have been derived by starting with a binary logit/probit model and generalizing it to allow for more than two outcomes.

The proportional-odds ordered logit model is so called because, if we consider the odds $\mathrm{odds}(k) = P(Y \leq k)/P(Y > k)$, then $\mathrm{odds}(k_1)$ and $\mathrm{odds}(k_2)$ have the same ratio for all independent variable combinations. The model is based on the principle that the only effect of combining adjoining categories in ordered categorical regression problems should be a loss of efficiency in estimating the regression parameters (McCullagh 1980). This model was also described by McKelvey and Zavoina (1975) and, previously, by Aitchison and Silvey (1957) in a different algebraic form. Brant (1990) offers a set of diagnostics for the model.

Peterson and Harrell (1990) suggest a model that allows nonproportional odds for a subset of the explanatory variables. `ologit` does not allow this, but a model similar to this was implemented by Fu (1998).

The stereotype model rejects the principle on which the ordered logit model is based. Anderson (1984) argues that there are two distinct types of ordered categorical variables: "grouped continuous", such as income, where the "type a" model applies; and "assessed", such as extent of pain relief, where the stereotype model applies. Greenland (1985) independently developed the same model. The stereotype model starts with a multinomial logistic regression model and imposes constraints on this model.

Goodness of fit for `ologit` can be evaluated by comparing the likelihood value with that obtained by fitting the model with `mlogit`. Let $\ln L_1$ be the log-likelihood value reported by `ologit`, and let $\ln L_0$ be the log-likelihood value reported by `mlogit`. If there are p independent variables (excluding the constant) and k categories, `mlogit` will estimate $p(k-1)$ additional parameters. We can then perform a "likelihood-ratio test", that is, calculate $-2(\ln L_1 - \ln L_0)$, and compare it with $\chi^2\{p(k-2)\}$. This test is suggestive only because the ordered logit model is not nested within the multinomial logit model. A large value of $-2(\ln L_1 - \ln L_0)$ should, however, be taken as evidence of poorness of fit. Marginally large values, on the other hand, should not be taken too seriously.

The coefficients and cutpoints are estimated using maximum likelihood as described in [R] **maximize**. In our parameterization, no constant appears, because the effect is absorbed into the cutpoints.

`ologit` and `oprobit` begin by tabulating the dependent variable. Category $i = 1$ is defined as the minimum value of the variable, $i = 2$ as the next ordered value, and so on, for the empirically determined k categories.

The probability of a given observation for ordered logit is

$$p_{ij} = \Pr(y_j = i) = \Pr\Big(\kappa_{i-1} < \mathbf{x}_j\boldsymbol{\beta} + u \leq \kappa_i\Big)$$
$$= \frac{1}{1+\exp(-\kappa_i + \mathbf{x}_j\boldsymbol{\beta})} - \frac{1}{1+\exp(-\kappa_{i-1} + \mathbf{x}_j\boldsymbol{\beta})}$$

κ_0 is defined as $-\infty$ and κ_k as $+\infty$.

For ordered probit, the probability of a given observation is

$$p_{ij} = \Pr(y_j = i) = \Pr\Big(\kappa_{i-1} < \mathbf{x}_j\boldsymbol{\beta} + u \leq \kappa_i\Big)$$
$$= \Phi\Big(\kappa_i - \mathbf{x}_j\boldsymbol{\beta}\Big) - \Phi\Big(\kappa_{i-1} - \mathbf{x}_j\boldsymbol{\beta}\Big)$$

where $\Phi(\cdot)$ is the standard normal cumulative distribution function.

The log likelihood is

$$\ln L = \sum_{j=1}^{N} w_j \sum_{i=1}^{k} I_i(y_j)\ln p_{ij}$$

where w_j is an optional weight and

$$I_i(y_j) = \begin{cases} 1, \text{ if } y_j = i \\ 0, \text{ otherwise} \end{cases}$$

`ologit` and `oprobit` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

ologit postestimation — Postestimation tools for ologit

Description

The following postestimation commands are available after `ologit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
    outcome(outcome) nooffset]

predict [type] { stub* | newvarlist } [if] [in], scores
```

statistic	Description
Main	
`pr`	predicted probabilities; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction

If you do not specify `outcome()`, `pr` (with one new variable specified) assumes `outcome(#1)`.

You specify one or k new variables with `pr`, where k is the number of outcomes.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the predicted probabilities. If you do not also specify the `outcome()` option, you specify k new variables, where k is the number of categories of the dependent variable. Say that you fit a model by typing `ologit result x1 x2`, and `result` takes on three values. Then you could type `predict p1 p2 p3` to obtain all three predicted probabilities. If you specify the `outcome()` option, you must specify one new variable. Say that `result` takes on the values 1, 2, and 3. Typing `predict p1, outcome(1)` would produce the same `p1`.

`xb` calculates the linear prediction. You specify one new variable, for example, `predict linear, xb`. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.

`stdp` calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(`*outcome*`)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of `#1`, `#2`, ..., with `#1` meaning the first category of the dependent variable, `#2` meaning the second category, etc.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `ologit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was k, then

the first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\mathbf{b})$;

the second new variable will contain $\partial \ln L/\partial\kappa_1$;

the third new variable will contain $\partial \ln L/\partial\kappa_2$;

...

and the kth new variable will contain $\partial \ln L/\partial\kappa_{k-1}$, where κ_i refers to the ith cutpoint.

Remarks

See [U] **20 Estimation and postestimation commands** for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] **lrtest** for performing likelihood-ratio tests.

▷ Example 1

In example 2 of [R] **ologit**, we fit the model `ologit rep77 foreign length mpg`. The `predict` command can be used to obtain the predicted probabilities.

We type `predict` followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is "poor", and the highest is "excellent". We have five categories, so we must type five names following `predict`; the choice of names is up to us:

```
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list exc good make model rep78 if rep77>=., sep(4) divider
```

	exc	good	make	model	rep78
3.	.0033341	.0393056	AMC	Spirit	.
10.	.0098392	.1070041	Buick	Opel	.
32.	.0023406	.0279497	Ford	Fiesta	Good
44.	.015697	.1594413	Merc.	Monarch	Average
53.	.065272	.4165188	Peugeot	604	.
56.	.005187	.059727	Plym.	Horizon	Average
57.	.0261461	.2371826	Plym.	Sapporo	.
63.	.0294961	.2585825	Pont.	Phoenix	.

The eight cars listed were introduced after 1977, so they do not have 1977 repair records in our data. We predicted what their 1977 repair records might have been using the fitted model. We see that, based on its characteristics, the Peugeot 604 had about a $41.65 + 6.53 \approx 48.2\%$ chance of a good or excellent repair record. The Ford Fiesta, which had only a 3% chance of a good or excellent repair record, in fact, had a good record when it was introduced in the following year.

◁

❑ Technical note

For ordered logit, `predict, xb` produces $S_j = x_{1j}\beta_1 + x_{2j}\beta_2 + \cdots + x_{kj}\beta_k$. The ordered-logit predictions are then the probability that $S_j + u_j$ lies between a pair of cutpoints, κ_{i-1} and κ_i. Some handy formulas are

$$\Pr(S_j + u_j < \kappa) = 1/(1 + e^{S_j - \kappa})$$
$$\Pr(S_j + u_j > \kappa) = 1 - 1/(1 + e^{S_j - \kappa})$$
$$\Pr(\kappa_1 < S_j + u_j < \kappa_2) = 1/(1 + e^{S_j - \kappa_2}) - 1/(1 + e^{S_j - \kappa_1})$$

Rather than using `predict` directly, we could calculate the predicted probabilities by hand. If we wished to obtain the predicted probability that the repair record is excellent and the probability that it is good, we look back at `ologit`'s output to obtain the cutpoints. We find that "good" corresponds to the interval `/cut3` $< S_j + u <$ `/cut4` and "excellent" to the interval $S_j + u >$ `/cut4`:

```
. predict score, xb
. generate probgood = 1/(1+exp(score-_b[/cut4])) - 1/(1+exp(score-_b[/cut3]))
. generate probexc = 1 - 1/(1+exp(score-_b[/cut4]))
```

The results of our calculation will be the same as those produced in the previous example. We refer to the estimated cutpoints just as we would any coefficient, so `_b[/cut3]` refers to the value of the `/cut3` coefficient; see [U] **13.5 Accessing coefficients and standard errors**.

❑

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

[R] **ologit** — Ordered logistic regression

[U] **20 Estimation and postestimation commands**

Title

oneway — One-way analysis of variance

Syntax

`oneway` *response_var factor_var* [*if*] [*in*] [*weight*] [, *options*]

options	Description
Main	
`bonferroni`	Bonferroni multiple-comparison test
`scheffe`	Scheffé multiple-comparison test
`sidak`	Šidák multiple-comparison test
`tabulate`	produce summary table
[`no`]`means`	include or suppress means; default is `means`
[`no`]`standard`	include or suppress standard deviations; default is `standard`
[`no`]`freq`	include or suppress frequencies; default is `freq`
[`no`]`obs`	include or suppress number of obs; default is `obs` if data are weighted
`noanova`	suppress the ANOVA table
`nolabel`	show numeric codes, not labels
`wrap`	do not break wide tables
`missing`	treat missing values as categories

`by` is allowed; see [D] **by**.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Linear models and related > ANOVA/MANOVA > One-way ANOVA

Description

The `oneway` command reports one-way analysis-of-variance (ANOVA) models and performs multiple-comparison tests.

If you wish to fit more complicated ANOVA layouts or wish to fit analysis-of-covariance (ANCOVA) models, see [R] **anova**.

See [D] **encode** for examples of fitting ANOVA models on string variables.

See [R] **loneway** for an alternative `oneway` command with slightly different features.

Options

Main

`bonferroni` reports the results of a Bonferroni multiple-comparison test.

`scheffe` reports the results of a Scheffé multiple-comparison test.

`sidak` reports the results of a Šidák multiple-comparison test.

`tabulate` produces a table of summary statistics of the *response_var* by levels of the *factor_var*. The table includes the mean, standard deviation, frequency, and, if the data are weighted, the number of observations. Individual elements of the table may be included or suppressed by using the [`no`]`means`, [`no`]`standard`, [`no`]`freq`, and [`no`]`obs` options. For example, typing

```
oneway response factor, tabulate means standard
```

produces a summary table that contains only the means and standard deviations. You could achieve the same result by typing

```
oneway response factor, tabulate nofreq
```

[`no`]`means` includes or suppresses only the means from the table produced by the `tabulate` option. See `tabulate` above.

[`no`]`standard` includes or suppresses only the standard deviations from the table produced by the `tabulate` option. See `tabulate` above.

[`no`]`freq` includes or suppresses only the frequencies from the table produced by the `tabulate` option. See `tabulate` above.

[`no`]`obs` includes or suppresses only the reported number of observations from the table produced by the `tabulate` option. If the data are not weighted, only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See `tabulate` above.

`noanova` suppresses the display of the ANOVA table.

`nolabel` causes the numeric codes to be displayed rather than the value labels in the ANOVA and multiple-comparison test tables.

`wrap` requests that Stata not break up wide tables to make them more readable.

`missing` requests that missing values of *factor_var* be treated as a category rather than as observations to be omitted from the analysis.

Remarks

Remarks are presented under the following headings:

Introduction
Obtaining observed means
Multiple-comparison tests
Weighted data

Introduction

The `oneway` command reports one-way ANOVA models. To perform a one-way layout of a variable called `endog` on `exog`, type `oneway endog exog`.

▷ Example 1

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following dataset:

```
. use http://www.stata-press.com/data/r12/apple
(Apple trees)

. describe
Contains data from http://www.stata-press.com/data/r12/apple.dta
  obs:            10                          Apple trees
 vars:             2                          16 Jan 2011 11:23
 size:           100
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
treatment       int    %8.0g                  Fertilizer
weight          double %10.0g                 Average weight in grams
-------------------------------------------------------------------------------
Sorted by:

. list, abbreviate(10)

     +-------------------+
     | treatment   weight |
     |-------------------|
  1. |         1    117.5 |
  2. |         1    113.8 |
  3. |         1    104.4 |
  4. |         2     48.9 |
  5. |         2     50.4 |
     |-------------------|
  6. |         2     58.9 |
  7. |         3     70.4 |
  8. |         3     86.9 |
  9. |         4     87.7 |
 10. |         4     67.3 |
     +-------------------+
```

To obtain the one-way ANOVA results, we type

```
. oneway weight treatment
                        Analysis of Variance
    Source              SS         df      MS            F     Prob > F
------------------------------------------------------------------------
Between groups      5295.54433      3   1765.18144     21.46     0.0013
 Within groups      493.591667      6   82.2652778
------------------------------------------------------------------------
    Total             5789.136      9   643.237333
Bartlett's test for equal variances:  chi2(3) =   1.3900  Prob>chi2 = 0.708
```

We find significant (at better than the 1% level) differences among the four concentrations.

◁

❑ Technical note

Rather than using the `oneway` command, we could have performed this analysis by using `anova`. Example 1 in [R] **anova** repeats this same analysis. You may wish to compare the output.

You will find the `oneway` command quicker than the `anova` command, and, as you will learn, `oneway` allows you to perform multiple-comparison tests. On the other hand, `anova` will let you generate predictions, examine the covariance matrix of the estimators, and perform more general hypothesis tests.

❑

❑ Technical note

Although the output is a usual ANOVA table, let's run through it anyway. The between-group sum of squares for the model is 5295.5 with 3 degrees of freedom, resulting in a mean square of $5295.5/3 \approx 1765.2$. The corresponding F statistic is 21.46 and has a significance level of 0.0013. Thus the model appears to be significant at the 0.13% level.

The second line summarizes the within-group (residual) variation. The within-group sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27.

The between- and residual-group variations sum to the total sum of squares (TSS), which is reported as 5789.1 in the last line of the table. This is the TSS of `weight` after removal of the mean. Similarly, the between plus residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.

At the bottom of the table, Bartlett's test for equal variances is reported. The value of the statistic is 1.39. The corresponding significance level (χ^2 with 3 degrees of freedom) is 0.708, so we cannot reject the assumption that the variances are homogeneous.

❑

Obtaining observed means

▷ Example 2

We typed `oneway weight treatment` to obtain an ANOVA table of weight of fruit by fertilizer concentration. Although we obtained the table, we obtained no information on which fertilizer seems to work the best. If we add the `tabulate` option, we obtain that additional information:

```
. oneway weight treatment, tabulate
```

Fertilizer	Summary of Average weight in grams Mean	Std. Dev.	Freq.
1	111.9	6.7535176	3
2	52.733333	5.3928966	3
3	78.65	11.667262	2
4	77.5	14.424978	2
Total	80.62	25.362124	10

Analysis of Variance

Source	SS	df	MS	F	Prob > F
Between groups	5295.54433	3	1765.18144	21.46	0.0013
Within groups	493.591667	6	82.2652778		
Total	5789.136	9	643.237333		

```
Bartlett's test for equal variances:  chi2(3) =   1.3900  Prob>chi2 = 0.708
```

We find that the average weight was largest when we used fertilizer concentration 1.

◁

Multiple-comparison tests

▷ Example 3

`oneway` can also perform multiple-comparison tests using either Bonferroni, Scheffé, or Šidák normalizations. For instance, to obtain the Bonferroni multiple-comparison test, we specify the `bonferroni` option:

```
. oneway weight treatment, bonferroni
                        Analysis of Variance
    Source              SS         df      MS            F     Prob > F
------------------------------------------------------------------------
Between groups      5295.54433      3   1765.18144     21.46     0.0013
 Within groups      493.591667      6   82.2652778
------------------------------------------------------------------------
    Total             5789.136      9   643.237333
Bartlett's test for equal variances:  chi2(3) =   1.3900  Prob>chi2 = 0.708
             Comparison of Average weight in grams by Fertilizer
                                (Bonferroni)
Row Mean-
Col Mean |          1          2          3
---------+---------------------------------
       2 |   -59.1667
         |      0.001
         |
       3 |     -33.25    25.9167
         |      0.042      0.122
         |
       4 |      -34.4    24.7667      -1.15
         |      0.036      0.146      1.000
```

The results of the Bonferroni test are presented as a matrix. The first entry, -59.17, represents the difference between fertilizer concentrations 2 and 1 (labeled "`Row Mean - Col Mean`" in the upper stub of the table). Remember that in the previous example we requested the `tabulate` option. Looking back, we find that the means of concentrations 1 and 2 are 111.90 and 52.73, respectively. Thus $52.73 - 111.90 = -59.17$.

Underneath that number is reported "`0.001`". This is the Bonferroni-adjusted significance of the difference. The difference is significant at the 0.1% level. Looking down the column, we see that concentration 3 is also worse than concentration 1 (4.2% level), as is concentration 4 (3.6% level).

On the basis of this evidence, we would use concentration 1 if we grew apple trees.

◁

▷ Example 4

We can just as easily obtain the Scheffé-adjusted significance levels. Rather than specifying the `bonferroni` option, we specify the `scheffe` option.

We will also add the noanova option to prevent Stata from redisplaying the ANOVA table:

```
. oneway weight treatment, noanova scheffe

            Comparison of Average weight in grams by Fertilizer
                                    (Scheffe)
Row Mean-
Col Mean |          1          2          3
---------+------------------------------------
       2 |   -59.1667
         |      0.001
         |
       3 |     -33.25    25.9167
         |       0.039      0.101
         |
       4 |       -34.4    24.7667      -1.15
         |       0.034      0.118      0.999
```

The differences are the same as those we obtained in the Bonferroni output, but the significance levels are not. According to the Bonferroni-adjusted numbers, the significance of the difference between fertilizer concentrations 1 and 3 is 4.2%. The Scheffé-adjusted significance level is 3.9%.

We will leave it to you to decide which results are more accurate.

◁

▷ Example 5

Let's conclude this example by obtaining the Šidák-adjusted multiple-comparison tests. We do this to illustrate Stata's capabilities to calculate these results, because searching across adjustment methods until you find the results you want is not a valid technique for obtaining significance levels.

```
. oneway weight treatment, noanova sidak

            Comparison of Average weight in grams by Fertilizer
                                    (Sidak)
Row Mean-
Col Mean |          1          2          3
---------+------------------------------------
       2 |   -59.1667
         |      0.001
         |
       3 |     -33.25    25.9167
         |       0.041      0.116
         |
       4 |       -34.4    24.7667      -1.15
         |       0.035      0.137      1.000
```

We find results that are similar to the Bonferroni-adjusted numbers.

◁

Henry Scheffé (1907–1977) was born in New York. He studied mathematics at the University of Wisconsin, gaining a doctorate with a dissertation on differential equations. He taught mathematics at Wisconsin, Oregon State University, and Reed College, but his interests changed to statistics and he joined Wilks at Princeton. After periods at Syracuse, UCLA, and Columbia, Scheffé settled in Berkeley from 1953. His research increasingly focused on linear models and particularly ANOVA, on which he produced a celebrated monograph. His death was the result of a bicycle accident.

Weighted data

▷ Example 6

oneway can work with both weighted and unweighted data. Let's assume that we wish to perform a one-way layout of the death rate on the four census regions of the United States using state data. Our data contain three variables, drate (the death rate), region (the region), and pop (the population of the state).

To fit the model, we type oneway drate region [weight=pop], although we typically abbreviate weight as w. We will also add the tabulate option to demonstrate how the table of summary statistics differs for weighted data:

```
. use http://www.stata-press.com/data/r12/census8
(1980 Census data by state)
. oneway drate region [w=pop], tabulate
(analytic weights assumed)
```

Census region	Summary of Death Rate Mean	Std. Dev.	Freq.	Obs.
NE	97.15	5.82	49135283	9
N Cntrl	88.10	5.58	58865670	12
South	87.05	10.40	74734029	16
West	75.65	8.23	43172490	13
Total	87.34	10.43	2.259e+08	50

Analysis of Variance

Source	SS	df	MS	F	Prob > F
Between groups	2360.92281	3	786.974272	12.17	0.0000
Within groups	2974.09635	46	64.6542685		
Total	5335.01916	49	108.877942		

```
Bartlett's test for equal variances:  chi2(3) =   5.4971  Prob>chi2 = 0.139
```

When the data are weighted, the summary table has four columns rather than three. The column labeled "Freq." reports the sum of the weights. The overall frequency is 2.259×10^8, meaning that there are approximately 226 million people in the United States.

The ANOVA table is appropriately weighted. Also see [U] **11.1.6 weight**.

◁

Saved results

oneway saves the following in r():

Scalars

r(N)	number of observations	r(df_m)	between-group degrees of freedom
r(F)	F statistic	r(rss)	within-group sum of squares
r(df_r)	within-group degrees of freedom	r(chi2bart)	Bartlett's χ^2
r(mss)	between-group sum of squares	r(df_bart)	Bartlett's degrees of freedom

Methods and formulas

Methods and formulas are presented under the following headings:

One-way analysis of variance
Bartlett's test
Multiple-comparison tests

One-way analysis of variance

The model of one-way ANOVA is

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}$$

for levels $i = 1, \ldots, k$ and observations $j = 1, \ldots, n_i$. Define $\overline{y}_i$ as the (weighted) mean of y_{ij} over j and $\overline{y}$ as the overall (weighted) mean of y_{ij}. Define w_{ij} as the weight associated with y_{ij}, which is 1 if the data are unweighted. w_{ij} is normalized to sum to $n = \sum_i n_i$ if `aweights` are used and is otherwise not normalized. w_i refers to $\sum_j w_{ij}$, and w refers to $\sum_i w_i$.

The between-group sum of squares is then

$$S_1 = \sum_i w_i(\overline{y}_i - \overline{y})^2$$

The TSS is

$$S = \sum_i \sum_j w_{ij}(y_{ij} - \overline{y})^2$$

The within-group sum of squares is given by $S_e = S - S_1$.

The between-group mean square is $s_1^2 = S_1/(k-1)$, and the within-group mean square is $s_e^2 = S_e/(w-k)$. The test statistic is $F = s_1^2/s_e^2$. See, for instance, Snedecor and Cochran (1989).

Bartlett's test

Bartlett's test assumes that you have m independent, normal, random samples and tests the hypothesis $\sigma_1^2 = \sigma_2^2 = \cdots = \sigma_m^2$. The test statistic, M, is defined as

$$M = \frac{(T-m)\ln\widehat{\sigma}^2 - \sum(T_i - 1)\ln\widehat{\sigma}_i^2}{1 + \frac{1}{3(m-1)}\left\{\left(\sum \frac{1}{T_i - 1}\right) - \frac{1}{T-m}\right\}}$$

where there are T overall observations, T_i observations in the ith group, and

$$(T_i - 1)\widehat{\sigma}_i^2 = \sum_{j=1}^{T_i}(y_{ij} - \overline{y}_i)^2$$

$$(T-m)\widehat{\sigma}^2 = \sum_{i=1}^{m}(T_i - 1)\widehat{\sigma}_i^2$$

An approximate test of the homogeneity of variance is based on the statistic M with critical values obtained from the χ^2 distribution of $m-1$ degrees of freedom. See Bartlett (1937) or Draper and Smith (1998, 56–57).

Multiple-comparison tests

Let's begin by reviewing the logic behind these adjustments. The "standard" t statistic for the comparison of two means is

$$t = \frac{\overline{y}_i - \overline{y}_j}{s\sqrt{\frac{1}{n_i} + \frac{1}{n_j}}}$$

where s is the overall standard deviation, $\overline{y}_i$ is the measured average of y in group i, and n_i is the number of observations in the group. We perform hypothesis tests by calculating this t statistic. We simultaneously choose a critical level, α, and look up the t statistic corresponding to that level in a table. We reject the hypothesis if our calculated t exceeds the value we looked up. Alternatively, because we have a computer at our disposal, we calculate the significance level e corresponding to our calculated t statistic, and if $e < \alpha$, we reject the hypothesis.

This logic works well when we are performing one test. Now consider what happens when we perform several separate tests, say, n of them. Let's assume, just for discussion, that we set α equal to 0.05 and that we will perform six tests. For each test, we have a 0.05 probability of falsely rejecting the equality-of-means hypothesis. Overall, then, our chances of falsely rejecting *at least one* of the hypotheses is $1 - (1 - 0.05)^6 \approx 0.26$ if the tests are independent.

The idea behind multiple-comparison tests is to control for the fact that we will perform multiple tests and to reduce our overall chances of falsely rejecting each hypothesis to α rather than letting our chances increase with each additional test. (See Miller [1981] and Hochberg and Tamhane [1987] for rather advanced texts on multiple-comparison procedures.)

The Bonferroni adjustment (see Miller [1981]; also see van Belle et al. [2004, 534–537]) does this by (falsely but approximately) asserting that the critical level we should use, a, is the true critical level, α, divided by the number of tests, n; that is, $a = \alpha/n$. For instance, if we are going to perform six tests, each at the 0.05 significance level, we want to adopt a critical level of $0.05/6 \approx 0.00833$.

We can just as easily apply this logic to e, the significance level associated with our t statistic, as to our critical level α. If a comparison has a calculated significance of e, then its "real" significance, adjusted for the fact of n comparisons, is $n \times e$. If a comparison has a significance level of, say, 0.012, and we perform six tests, then its "real" significance is 0.072. If we adopt a critical level of 0.05, we cannot reject the hypothesis. If we adopt a critical level of 0.10, we can reject it.

Of course, this calculation can go above 1, but that just means that there is no $\alpha < 1$ for which we could reject the hypothesis. (This situation arises because of the crude nature of the Bonferroni adjustment.) Stata handles this case by simply calling the significance level 1. Thus the formula for the Bonferroni significance level is

$$e_b = \min(1, en)$$

where $n = k(k-1)/2$ is the number of comparisons.

The Šidák adjustment (Šidák [1967]; also see Winer, Brown, and Michels [1991, 165–166]) is slightly different and provides a tighter bound. It starts with the assertion that

$$a = 1 - (1 - \alpha)^{1/n}$$

Turning this formula around and substituting calculated significance levels, we obtain

$$e_s = \min\left\{1, 1 - (1 - e)^n\right\}$$

For example, if the calculated significance is 0.012 and we perform six tests, the "real" significance is approximately 0.07.

The Scheffé test (Scheffé [1953, 1959]; also see Kuehl [2000, 97–98]) differs in derivation, but it attacks the same problem. Let there be k means for which we want to make all the pairwise tests. Two means are declared significantly different if

$$t \geq \sqrt{(k-1)F(\alpha; k-1, \nu)}$$

where $F(\alpha; k-1, \nu)$ is the α-critical value of the F distribution with $k-1$ numerator and ν denominator degrees of freedom. Scheffé's test has the nicety that it never declares a contrast significant if the overall F test is not significant.

Turning the test around, Stata calculates a significance level

$$\widehat{e} = F\left(\frac{t^2}{k-1}, k-1, \nu\right)$$

For instance, you have a calculated t statistic of 4.0 with 50 degrees of freedom. The simple t test says that the significance level is 0.00021. The F test equivalent, 16 with 1 and 50 degrees of freedom, says the same. If you are comparing three means, however, you calculate an F test of 8.0 with 2 and 50 degrees of freedom, which says that the significance level is 0.0010.

Title

oprobit — Ordered probit regression

Syntax

`oprobit` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [`,` *options*]

options	Description
Model	
`offset(`*varname*`)`	include *varname* in model with coefficient constrained to 1
`constraints(`*constraints*`)`	apply specified linear constraints
`collinear`	keep collinear variables
SE/Robust	
`vce(`*vcetype*`)`	*vcetype* may be `oim`, `robust`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`nocnsreport`	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
`coeflegend`	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

`bootstrap`, `by`, `fracpoly`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.

`coeflegend` does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Ordinal outcomes > Ordered probit regression

Description

`oprobit` fits ordered probit models of ordinal variable *depvar* on the independent variables *indepvars*. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to "higher" outcomes.

See [R] **logistic** for a list of related estimation commands.

Options

Model

`offset(`*varname*`)`, `constraints(`*constraints*`)`, `collinear`; see [R] **estimation options**.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

The following option is available with `oprobit` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

An ordered probit model is used to estimate relationships between an ordinal dependent variable and a set of independent variables. An *ordinal* variable is a variable that is categorical and ordered, for instance, "poor", "good", and "excellent", which might indicate a person's current health status or the repair record of a car. If there are only two outcomes, see [R] **logistic**, [R] **logit**, and [R] **probit**. This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [R] **mlogit**. This entry is concerned only with models in which the outcomes can be ordered.

In ordered probit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome i corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

u_j is assumed to be normally distributed. In either case, we estimate the coefficients β_1, β_2, …, β_k together with the cutpoints κ_1, κ_2, …, κ_{I-1}, where I is the number of possible outcomes. κ_0 is taken as $-\infty$, and κ_I is taken as $+\infty$. All of this is a direct generalization of the ordinary two-outcome probit model.

Example 1

In example 2 of [R] **ologit**, we use a variation of the automobile dataset (see [U] **1.2.2 Example datasets**) to analyze the 1977 repair records of 66 foreign and domestic cars. We use ordered logit to explore the relationship of `rep77` in terms of `foreign` (origin of manufacture), `length` (a proxy for size), and `mpg`. Here we fit the same model using ordered probit rather than ordered logit:

```
. use http://www.stata-press.com/data/r12/fullauto
(Automobile Models)
. oprobit rep77 foreign length mpg

Iteration 0:   log likelihood = -89.895098
Iteration 1:   log likelihood = -78.106316
Iteration 2:   log likelihood = -78.020086
Iteration 3:   log likelihood = -78.020025
Iteration 4:   log likelihood = -78.020025
Ordered probit regression                       Number of obs   =         66
                                                LR chi2(3)      =      23.75
                                                Prob > chi2     =     0.0000
Log likelihood = -78.020025                     Pseudo R2       =     0.1321

      length |   .0468675    .012648     3.71   0.000      .022078    .0716571
         mpg |   .1304559   .0378628     3.45   0.001     .0562463    .2046656
-------------+----------------------------------------------------------------
       /cut1 |    10.1589   3.076754                      4.128577    16.18923
       /cut2 |   11.21003   3.107527                      5.119389    17.30067
       /cut3 |   12.54561   3.155233                      6.361467    18.72975
       /cut4 |   13.98059   3.218793                      7.671874    20.28931
------------------------------------------------------------------------------
```

We find that foreign cars have better repair records, as do larger cars and cars with better mileage ratings.

Saved results

oprobit saves the following in e():

Scalars

e(N)	number of observations
e(N_cd)	number of completely determined observations
e(k_cat)	number of categories
e(k)	number of parameters
e(k_aux)	number of auxiliary parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(r2_p)	pseudo-R-squared
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance of model test
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	oprobit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(cat)	category values
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

oprobit is implemented as an ado-file.

See *Methods and formulas* of [R] **ologit**.

Title

oprobit postestimation — Postestimation tools for oprobit

Description

The following postestimation commands are available after `oprobit`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
    outcome(outcome) nooffset]

predict [type] { stub* | newvarlist } [if] [in], scores
```

statistic	Description
Main	
`pr`	predicted probabilities; the default
`xb`	linear prediction
`stdp`	standard error of the linear prediction

If you do not specify `outcome()`, `pr` (with one new variable specified) assumes `outcome(#1)`.

You specify one or k new variables with `pr`, where k is the number of outcomes.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the predicted probabilities. If you do not also specify the `outcome()` option, you specify k new variables, where k is the number of categories of the dependent variable. Say that you fit a model by typing `oprobit result x1 x2`, and `result` takes on three values. Then you could type `predict p1 p2 p3` to obtain all three predicted probabilities. If you specify the `outcome()` option, you must specify one new variable. Say that `result` takes on values 1, 2, and 3. Typing `predict p1, outcome(1)` would produce the same `p1`.

`xb` calculates the linear prediction. You specify one new variable, for example, `predict linear, xb`. The linear prediction is defined ignoring the contribution of the estimated cutpoints.

`stdp` calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(`*outcome*`)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of `#1`, `#2`, ..., with `#1` meaning the first category of the dependent variable, `#2` meaning the second category, etc.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `oprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was k, then

the first new variable will contain $\partial \ln L/\partial(\mathbf{x}_j\mathbf{b})$;

the second new variable will contain $\partial \ln L/\partial\kappa_1$;

the third new variable will contain $\partial \ln L/\partial\kappa_2$;

...

and the kth new variable will contain $\partial \ln L/\partial\kappa_{k-1}$, where κ_i refers to the ith cutpoint.

Remarks

See [U] **20 Estimation and postestimation commands** for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] **lrtest** for performing likelihood-ratio tests.

▷ Example 1

In example 1 of [R] **oprobit**, we fit the model `oprobit rep77 foreign length mpg`. The `predict` command can be used to obtain the predicted probabilities. We type `predict` followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is "poor" and the highest is "excellent". We have five categories, so we must type five names following `predict`; the choice of names is up to us:

```
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list make model exc good if rep77>=., sep(4) divider
```

	make	model	exc	good
3.	AMC	Spirit	.0006044	.0351813

63.	Pont.	Phoenix	.0234156	.266771

◁

❑ Technical note

For ordered probit, `predict, xb` produces $S_j = x_{1j}\beta_1 + x_{2j}\beta_2 + \cdots + x_{kj}\beta_k$. Ordered probit is identical to ordered logit, except that we use different distribution functions for calculating probabilities. The ordered-probit predictions are then the probability that $S_j + u_j$ lies between a pair of cutpoints κ_{i-1} and κ_i. The formulas for ordered probit are

$$\Pr(S_j + u < \kappa) = \Phi(\kappa - S_j)$$
$$\Pr(S_j + u > \kappa) = 1 - \Phi(\kappa - S_j) = \Phi(S_j - \kappa)$$
$$\Pr(\kappa_1 < S_j + u < \kappa_2) = \Phi(\kappa_2 - S_j) - \Phi(\kappa_1 - S_j)$$

Rather than using `predict` directly, we could calculate the predicted probabilities by hand.

```
. predict pscore, xb
. generate probexc = normal(pscore-_b[/cut4])
. generate probgood = normal(_b[/cut4]-pscore) - normal(_b[/cut3]-pscore)
```

❑

Methods and formulas

All postestimation tools listed above are implemented as ado-files.

Title

orthog — Orthogonalize variables and compute orthogonal polynomials

Syntax

Orthogonalize variables

```
orthog [varlist] [if] [in] [weight] , generate(newvarlist) [matrix(matname)]
```

Compute orthogonal polynomial

```
orthpoly varname [if] [in] [weight] ,
    { generate(newvarlist) | poly(matname) } [degree(#)]
```

`orthpoly` requires that `generate(`*newvarlist*`)` or `poly(`*matname*`)`, or both, be specified.
varlist may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`iweights`, `fweights`, `pweights`, and `aweights` are allowed, see [U] **11.1.6 weight**.

orthpoly

Data > Create or change data > Other variable-creation commands > Orthogonal polynomials

Description

`orthog` orthogonalizes a set of variables, creating a new set of orthogonal variables (all of type `double`), using a modified Gram–Schmidt procedure (Golub and Van Loan 1996). The order of the variables determines the orthogonalization; hence, the "most important" variables should be listed first.

Execution time is proportional to the square of the number of variables. With many (>10) variables, `orthog` will be fairly slow.

`orthpoly` computes orthogonal polynomials for one variable.

Options for orthog

Main

`generate(`*newvarlist*`)` is required. `generate()` creates new orthogonal variables of type `double`. For `orthog`, *newvarlist* will contain the orthogonalized *varlist*. If *varlist* contains d variables, then so will *newvarlist*. *newvarlist* can be specified by giving a list of exactly d new variable names, or it can be abbreviated using the styles *newvar*`1-`*newvard* or *newvar*`*`. For these two styles of abbreviation, new variables *newvar*`1`, *newvar*`2`, ..., *newvard* are generated.

`matrix(`*matname*`)` creates a $(d+1) \times (d+1)$ matrix containing the matrix R defined by $X = QR$, where X is the $N \times (d+1)$ matrix representation of *varlist* plus a column of ones and Q is the $N \times (d+1)$ matrix representation of *newvarlist* plus a column of ones (d = number of variables in *varlist*, and N = number of observations).

Options for orthpoly

Main

`generate(`*newvarlist*`)` or `poly()`, or both, must be specified. `generate()` creates new orthogonal variables of type `double`. *newvarlist* will contain orthogonal polynomials of degree 1, 2, ..., d evaluated at *varname*, where d is as specified by `degree(`d`)`. *newvarlist* can be specified by giving a list of exactly d new variable names, or it can be abbreviated using the styles *newvar*`1-`*newvard* or *newvar*`*`. For these two styles of abbreviation, new variables *newvar*`1`, *newvar*`2`, ..., *newvard* are generated.

`poly(`*matname*`)` creates a $(d+1) \times (d+1)$ matrix called *matname* containing the coefficients of the orthogonal polynomials. The orthogonal polynomial of degree $i \leq d$ is

matname`[`i`, `$d+1$`] + `*matname*`[`i`, 1]*`*varname* `+` *matname*`[`i`, 2]*`*varname*^{2} `+` $\cdots$ `+` *matname*`[`i`, `i`]*`*varname*^{i}

The coefficients corresponding to the constant term are placed in the last column of the matrix. The last row of the matrix is all zeros, except for the last column, which corresponds to the constant term.

`degree(#)` specifies the highest-degree polynomial to include. Orthogonal polynomials of degree 1, 2, ..., d = # are computed. The default is $d = 1$.

Remarks

Orthogonal variables are useful for two reasons. The first is numerical accuracy for highly collinear variables. Stata's `regress` and other estimation commands can face much collinearity and still produce accurate results. But, at some point, these commands will drop variables because of collinearity. If you know with certainty that the variables are not perfectly collinear, you may want to retain all their effects in the model. If you use `orthog` or `orthpoly` to produce a set of orthogonal variables, all variables will be present in the estimation results.

Users are more likely to find orthogonal variables useful for the second reason: ease of interpreting results. `orthog` and `orthpoly` create a set of variables such that the "effects" of all the preceding variables have been removed from each variable. For example, if we issue the command

```
. orthog x1 x2 x3, generate(q1 q2 q3)
```

the effect of the constant is removed from `x1` to produce `q1`; the constant and `x1` are removed from `x2` to produce `q2`; and finally the constant, `x1`, and `x2` are removed from `x3` to produce `q3`. Hence,

$$\texttt{q1} = r_{01} + r_{11}\,\texttt{x1}$$
$$\texttt{q2} = r_{02} + r_{12}\,\texttt{x1} + r_{22}\,\texttt{x2}$$
$$\texttt{q3} = r_{03} + r_{13}\,\texttt{x1} + r_{23}\,\texttt{x2} + r_{33}\,\texttt{x3}$$

This effect can be generalized and written in matrix notation as

$$X = QR$$

where X is the $N \times (d+1)$ matrix representation of *varlist* plus a column of ones, and Q is the $N \times (d+1)$ matrix representation of *newvarlist* plus a column of ones (d = number of variables in *varlist* and N = number of observations). The $(d+1) \times (d+1)$ matrix R is a permuted upper-triangular matrix, that is, R would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column. Because Stata's estimation commands list the constant term last, this allows R, obtained via the `matrix()` option, to be used to transform estimation results.

▷ Example 1

Consider Stata's `auto.dta` dataset. Suppose that we postulate a model in which `price` depends on the car's `length`, `weight`, `headroom`, and trunk size (`trunk`). These predictors are collinear, but not extremely so—the correlations are not that close to 1:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. correlate length weight headroom trunk
(obs=74)
```

	length	weight	headroom	trunk
length	1.0000			
weight	0.9460	1.0000		
headroom	0.5163	0.4835	1.0000	
trunk	0.7266	0.6722	0.6620	1.0000

`regress` certainly has no trouble fitting this model:

```
. regress price length weight headroom trunk
```

Source	SS	df	MS		
Model	236016580	4	59004145	Number of obs	= 74
Residual	399048816	69	5783316.17	F(4, 69)	= 10.20
				Prob > F	= 0.0000
				R-squared	= 0.3716
				Adj R-squared	= 0.3352
Total	635065396	73	8699525.97	Root MSE	= 2404.9

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
length	-101.7092	42.12534	-2.41	0.018	-185.747	-17.67147
weight	4.753066	1.120054	4.24	0.000	2.518619	6.987512
headroom	-711.5679	445.0204	-1.60	0.114	-1599.359	176.2236
trunk	114.0859	109.9488	1.04	0.303	-105.2559	333.4277
_cons	11488.47	4543.902	2.53	0.014	2423.638	20553.31

However, we may believe a priori that `length` is the most important predictor, followed by `weight`, `headroom`, and `trunk`. We would like to remove the "effect" of `length` from all the other predictors, remove `weight` from `headroom` and `trunk`, and remove `headroom` from `trunk`. We can do this by running `orthog`, and then we fit the model again using the orthogonal variables:

```
. orthog length weight headroom trunk, gen(olength oweight oheadroom otrunk)
> matrix(R)
. regress price olength oweight oheadroom otrunk
```

Source	SS	df	MS	Number of obs =	74
Model	236016580	4	59004145	F(4, 69) =	10.20
Residual	399048816	69	5783316.17	Prob > F =	0.0000
				R-squared =	0.3716
				Adj R-squared =	0.3352
Total	635065396	73	8699525.97	Root MSE =	2404.9

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
olength	1265.049	279.5584	4.53	0.000	707.3454	1822.753
oweight	1175.765	279.5584	4.21	0.000	618.0617	1733.469
oheadroom	-349.9916	279.5584	-1.25	0.215	-907.6955	207.7122
otrunk	290.0776	279.5584	1.04	0.303	-267.6262	847.7815
_cons	6165.257	279.5584	22.05	0.000	5607.553	6722.961

Using the matrix `R`, we can transform the results obtained using the orthogonal predictors back to the metric of original predictors:

```
. matrix b = e(b)*inv(R)'
. matrix list b
b[1,5]
        length      weight    headroom       trunk       _cons
y1  -101.70924   4.7530659  -711.56789   114.08591   11488.475
```

◁

❑ Technical note

The matrix R obtained using the `matrix()` option with `orthog` can also be used to recover X (the original *varlist*) from Q (the orthogonalized *newvarlist*), one variable at a time. Continuing with the previous example, we illustrate how to recover the `trunk` variable:

```
. matrix C = R[1...,"trunk"]'
. matrix score double rtrunk = C
. compare rtrunk trunk
```

	count	difference minimum	difference average	difference maximum
rtrunk>trunk	74	1.42e-14	2.27e-14	3.55e-14
jointly defined	74	1.42e-14	2.27e-14	3.55e-14
total	74			

Here the recovered variable `rtrunk` is almost exactly the same as the original `trunk` variable. When you are orthogonalizing many variables, this procedure can be performed to check the numerical soundness of the orthogonalization. Because of the ordering of the orthogonalization procedure, the last variable and the variables near the end of the *varlist* are the most important ones to check.

❑

The `orthpoly` command effectively does for polynomial terms what the `orthog` command does for an arbitrary set of variables.

▷ Example 2

Again consider the auto.dta dataset. Suppose that we wish to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\,\texttt{weight} + \beta_2\,\texttt{weight}^2 + \beta_3\,\texttt{weight}^3 + \beta_4\,\texttt{weight}^4 + \epsilon$$

We will first compute the regression with natural polynomials:

```
. gen double w1 = weight
. gen double w2 = w1*w1
. gen double w3 = w2*w1
. gen double w4 = w3*w1
. correlate w1-w4
(obs=74)
```

	w1	w2	w3	w4
w1	1.0000			
w2	0.9915	1.0000		
w3	0.9665	0.9916	1.0000	
w4	0.9279	0.9679	0.9922	1.0000

```
. regress mpg w1-w4
```

Source	SS	df	MS		
Model	1652.73666	4	413.184164	Number of obs =	74
Residual	790.722803	69	11.4597508	F(4, 69) =	36.06
				Prob > F =	0.0000
				R-squared =	0.6764
				Adj R-squared =	0.6576
Total	2443.45946	73	33.4720474	Root MSE =	3.3852

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
w1	.0289302	.1161939	0.25	0.804	-.2028704	.2607307
w2	-.0000229	.0000566	-0.40	0.687	-.0001359	.0000901
w3	5.74e-09	1.19e-08	0.48	0.631	-1.80e-08	2.95e-08
w4	-4.86e-13	9.14e-13	-0.53	0.596	-2.31e-12	1.34e-12
_cons	23.94421	86.60667	0.28	0.783	-148.8314	196.7198

Some of the correlations among the powers of weight are very large, but this does not create any problems for regress. However, we may wish to look at the quadratic trend with the constant removed, the cubic trend with the quadratic and constant removed, etc. orthpoly will generate polynomial terms with this property:

```
. orthpoly weight, generate(pw*) deg(4) poly(P)
. regress mpg pw1-pw4
```

Source	SS	df	MS		
Model	1652.73666	4	413.184164	Number of obs =	74
Residual	790.722803	69	11.4597508	F(4, 69) =	36.06
				Prob > F =	0.0000
				R-squared =	0.6764
				Adj R-squared =	0.6576
Total	2443.45946	73	33.4720474	Root MSE =	3.3852

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
pw1	-4.638252	.3935245	-11.79	0.000	-5.423312	-3.853192
pw2	.8263545	.3935245	2.10	0.039	.0412947	1.611414
pw3	-.3068616	.3935245	-0.78	0.438	-1.091921	.4781982
pw4	-.209457	.3935245	-0.53	0.596	-.9945168	.5756028
_cons	21.2973	.3935245	54.12	0.000	20.51224	22.08236

Compare the p-values of the terms in the natural polynomial regression with those in the orthogonal polynomial regression. With orthogonal polynomials, it is easy to see that the pure cubic and quartic trends are not significant and that the constant, linear, and quadratic terms each have $p < 0.05$.

The matrix `P` obtained with the `poly()` option can be used to transform coefficients for orthogonal polynomials to coefficients for natural polynomials:

```
. orthpoly weight, poly(P) deg(4)
. matrix b = e(b)*P
. matrix list b
b[1,5]
          deg1        deg2        deg3        deg4       _cons
y1   .02893016  -.00002291   5.745e-09  -4.862e-13   23.944212
```

◁

Methods and formulas

`orthog` and `orthpoly` are implemented as ado-files.

`orthog`'s orthogonalization can be written in matrix notation as

$$X = QR$$

where X is the $N \times (d+1)$ matrix representation of *varlist* plus a column of ones and Q is the $N \times (d+1)$ matrix representation of *newvarlist* plus a column of ones ($d =$ number of variables in *varlist*, and $N =$ number of observations). The $(d+1) \times (d+1)$ matrix R is a permuted upper-triangular matrix; that is, R would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column.

Q and R are obtained using a modified Gram–Schmidt procedure; see Golub and Van Loan (1996, 218–219) for details. The traditional Gram–Schmidt procedure is notoriously unsound, but the modified procedure is good. `orthog` performs two passes of this procedure.

`orthpoly` uses the Christoffel–Darboux recurrence formula (Abramowitz and Stegun 1972).

Both `orthog` and `orthpoly` normalize the orthogonal variables such that

$$Q'WQ = MI$$

where $W = \text{diag}(w_1, w_2, \ldots, w_N)$ with weights $w_1, w_2, \ldots, w_N$ (all 1 if weights are not specified), and M is the sum of the weights (the number of observations if weights are not specified).

Title

pcorr — Partial and semipartial correlation coefficients

Syntax

`pcorr` *varname*$_1$ *varlist* [*if*] [*in*] [*weight*]

varname$_1$ and *varlist* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.
`by` is allowed; see [D] **by**.
`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Partial correlations

Description

`pcorr` displays the partial and semipartial correlation coefficients of *varname*$_1$ with each variable in *varlist* after removing the effects of all other variables in *varlist*. The squared correlations and corresponding significance are also reported.

Remarks

Assume that y is determined by x_1, x_2, ..., x_k. The partial correlation between y and x_1 is an attempt to estimate the correlation that would be observed between y and x_1 if the other x's did not vary. The semipartial correlation, also called part correlation, between y and x_1 is an attempt to estimate the correlation that would be observed between y and x_1 after the effects of all other x's are removed from x_1 but not from y.

Both squared correlations estimate the proportion of the variance of y that is explained by each predictor. The squared semipartial correlation between y and x_1 represents the proportion of variance in y that is explained by x_1 only. This squared correlation can also be interpreted as the decrease in the model's R^2 value that results from removing x_1 from the full model. Thus one could use the squared semipartial correlations as criteria for model selection. The squared partial correlation between y and x_1 represents the proportion of variance in y not associated with any other x's that is explained by x_1. Thus the squared partial correlation gives an estimate of how much of the variance of y not explained by the other x's is explained by x_1.

▷ Example 1

Using our automobile dataset (described in [U] **1.2.2 Example datasets**), we can obtain the simple correlations between `price`, `mpg`, `weight`, and `foreign` from `correlate` (see [R] **correlate**):

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. correlate price mpg weight foreign
(obs=74)
```

	price	mpg	weight	foreign
price	1.0000			
mpg	-0.4686	1.0000		
weight	0.5386	-0.8072	1.0000	
foreign	0.0487	0.3934	-0.5928	1.0000

Although `correlate` gave us the full correlation matrix, our interest is in just the first column. We find, for instance, that the higher the `mpg`, the lower the `price`. We obtain the partial and semipartial correlation coefficients by using `pcorr`:

```
. pcorr price mpg weight foreign
(obs=74)
Partial and semipartial correlations of price with
```

Variable	Partial Corr.	Semipartial Corr.	Partial Corr.^2	Semipartial Corr.^2	Significance Value
mpg	0.0352	0.0249	0.0012	0.0006	0.7693
weight	0.5488	0.4644	0.3012	0.2157	0.0000
foreign	0.5402	0.4541	0.2918	0.2062	0.0000

We now find that the partial and semipartial correlations of `price` with `mpg` are near 0. In the simple correlations, we found that `price` and `foreign` were virtually uncorrelated. In the partial and semipartial correlations, we find that `price` and `foreign` are positively correlated. The nonsignificance of `mpg` tells us that the amount in which R^2 decreases by removing `mpg` from the model is not significant. We find that removing either `weight` or `foreign` results in a significant drop in the R^2 of the model.

◁

❑ Technical note

Use caution when interpreting the above results. As we said at the outset, the partial and semipartial correlation coefficients are an *attempt* to estimate the correlation that would be observed if the effects of all other variables were taken out of both y and x or only x. `pcorr` makes it too easy to ignore the fact that we are fitting a model. In the example above, the model is

$$\texttt{price} = \beta_0 + \beta_1\texttt{mpg} + \beta_2\texttt{weight} + \beta_3\texttt{foreign} + \epsilon$$

which is, in all honesty, a rather silly model. Even if we accept the implied economic assumptions of the model—that consumers value `mpg`, `weight`, and `foreign`—do we really believe that consumers place equal value on every extra 1,000 pounds of weight? That is, have we correctly parameterized the model? If we have not, then the estimated partial and semipartial correlation coefficients may not represent what they claim to represent. Partial and semipartial correlation coefficients are a reasonable way to summarize data if we are convinced that the underlying model is reasonable. We should not, however, pretend that there is no underlying model and that these correlation coefficients are unaffected by the assumptions and parameterization.

❑

Saved results

pcorr saves the following in r():

Scalars

r(N)	number of observations
r(df)	degrees of freedom

Matrices

r(p_corr)	partial correlation coefficient vector
r(sp_corr)	semipartial correlation coefficient vector

Methods and formulas

pcorr is implemented as an ado-file.

Results are obtained by fitting a linear regression of *varname*$_1$ on *varlist*; see [R] **regress**. The partial correlation coefficient between *varname*$_1$ and each variable in *varlist* is then calculated as

$$\frac{t}{\sqrt{t^2+n-k}}$$

(Greene 2012, 37), where t is the t statistic, n is the number of observations, and k is the number of independent variables, including the constant but excluding any dropped variables.

The semipartial correlation coefficient between *varname*$_1$ and each variable in *varlist* is calculated as

$$\text{sign}(t)\sqrt{\frac{t^2(1-R^2)}{n-k}}$$

(Cohen et al. 2003, 89), where R^2 is the model R^2 value, and t, n, and k are as described above.

The significance is given by $2\Pr(t_{n-k} > |t|)$, where t_{n-k} follows a Student's t distribution with $n-k$ degrees of freedom.

Acknowledgment

The addition of semipartial correlation coefficients to pcorr is based on the pcorr2 command by Richard Williams, University of Notre Dame.

Statistics > Resampling > Permutation tests

Description

`permute` estimates p-values for permutation tests on the basis of Monte Carlo simulations. Typing

```
. permute permvar exp_list, reps(#): command
```

randomly permutes the values in *permvar* # times, each time executing *command* and collecting the associated values from the expression in *exp_list*.

These p-value estimates can be one-sided: $\Pr(T^* \leq T)$ or $\Pr(T^* \geq T)$. The default is two-sided: $\Pr(|T^*| \geq |T|)$. Here T^* denotes the value of the statistic from a randomly permuted dataset, and T denotes the statistic as computed on the original data.

permvar identifies the variable whose observed values will be randomly permuted.

command defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `permute`, as long as they follow standard Stata syntax; see [U] **11 Language syntax**. The `by` prefix may not be part of *command*.

exp_list specifies the statistics to be collected from the execution of *command*.

`permute` may be used for replaying results, but this feature is appropriate only when a dataset generated by `permute` is currently in memory or is identified by the `using` option. The variables specified in *varlist* in this context must be present in the respective dataset.

Options

Main

`reps(#)` specifies the number of random permutations to perform. The default is 100.

`left` or `right` requests that one-sided p-values be computed. If `left` is specified, an estimate of $\Pr(T^* \leq T)$ is produced, where T^* is the test statistic and T is its observed value. If `right` is specified, an estimate of $\Pr(T^* \geq T)$ is produced. By default, two-sided p-values are computed; that is, $\Pr(|T^*| \geq |T|)$ is estimated.

Options

`strata(`*varlist*`)` specifies that the permutations be performed within each stratum defined by the values of *varlist*.

`saving(`*filename*`[ , `*suboptions*` ])` creates a Stata data file (`.dta` file) consisting of (for each statistic in *exp_list*) a variable containing the replicates.

`double` specifies that the results for each replication be stored as `doubles`, meaning 8-byte reals. By default, they are stored as `floats`, meaning 4-byte reals.

`every(#)` specifies that results are to be written to disk every #th replication. `every()` should be specified only in conjunction with `saving()` when *command* takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See [P] **postfile**.

`replace` specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] **level**.

`noheader` suppresses display of the table header. This option implies the `nolegend` option.

`nolegend` suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

`verbose` requests that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`nodrop` prevents `permute` from dropping observations outside the `if` and `in` qualifiers. `nodrop` will also cause `permute` to ignore the contents of `e(sample)` if it exists as a result of running *command*. By default, `permute` temporarily drops out-of-sample observations.

`nodots` suppresses display of the replication dots. By default, one dot character is displayed for each successful replication. A red 'x' is displayed if *command* returns an error or if one of the values in *exp_list* is missing.

`noisily` requests that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(`*text*`)` specifies a title to be displayed above the table of permutation results; the default title is `Monte Carlo permutation results`.

Advanced

`eps(#)` specifies the numerical tolerance for testing $|T^*| \geq |T|$, $T^* \leq T$, or $T^* \geq T$. These are considered true if, respectively, $|T^*| \geq |T|-\#$, $T^* \leq T+\#$, or $T^* \geq T-\#$. The default is `1e-7`. You will not have to specify `eps()` under normal circumstances.

`nowarn` suppresses the printing of a warning message when *command* does not set `e(sample)`.

`force` suppresses the restriction that *command* may not specify weights or be a `svy` command. `permute` is not suited for weighted estimation, thus `permute` should not be used with weights or `svy`. `permute` reports an error when it encounters weights or `svy` in *command* if the `force` option is not specified. This is a seldom used option, so use it only if you know what you are doing!

`reject(`*exp*`)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

`seed(#)` sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling `permute`:

```
. set seed #
```

Remarks

Permutation tests determine the significance of the observed value of a test statistic in light of rearranging the order (permuting) of the observed values of a variable.

▷ Example 1

Suppose that we conducted an experiment to determine the effect of a treatment on the development of cells. Further suppose that we are restricted to six experimental units because of the extreme cost of the experiment. Thus three units are to be given a placebo, and three units are given the treatment. The measurement is the number of newly developed healthy cells. The following listing gives the hypothetical data, along with some summary statistics.

```
. input y treatment
            y  treatment
  1. 7 0
  2. 9 0
  3. 11 0
  4. 10 1
  5. 12 1
  6. 14 1
  7. end
. sort treatment
```

```
. summarize y
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
           y |          6        10.5    2.428992         7         14

. by treatment: summarize y

-------------------------------------------------------------------------------
-> treatment = 0
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
           y |          3           9           2         7         11

-------------------------------------------------------------------------------
-> treatment = 1
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
           y |          3          12           2        10         14
```

Clearly, there are more cells in the treatment group than in the placebo group, but a statistical test is needed to conclude that the treatment does affect the development of cells. If the sum of the treatment measures is our test statistic, we can use `permute` to determine the probability of observing 36 or more cells, given the observed data and assuming that there is no effect due to the treatment.

```
. set seed 1234

. permute y sum=r(sum), saving(permdish) right nodrop nowarn: sum y if treatment
(running summarize on estimation sample)

Permutation replications (100)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50
..................................................   100

Monte Carlo permutation results                 Number of obs   =          6

      command:  summarize y if treatment
          sum:  r(sum)
  permute var:  y

------------------------------------------------------------------------------
T             |     T(obs)       c       n   p=c/n   SE(p) [95% Conf. Interval]
--------------+---------------------------------------------------------------
          sum |         36      10     100  0.1000  0.0300   .0490047   .1762226
------------------------------------------------------------------------------

Note:  confidence interval is with respect to p=c/n.
Note:  c = #{T >= T(obs)}
```

We see that 10 of the 100 randomly permuted datasets yielded sums from the treatment group larger than or equal to the observed sum of 36. Thus the evidence is not strong enough, at the 5% level, to reject the null hypothesis that there is no effect of the treatment.

Because of the small size of this experiment, we could have calculated the exact permutation p-value from all possible permutations. There are six units, but we want the sum of the treatment units. Thus there are $\binom{6}{3} = 20$ permutation sums from the possible unique permutations.

$$
\begin{array}{cccc}
7+9+10=26 & 7+10+12=29 & 9+10+11=30 & 9+12+14=35 \\
7+9+11=27 & 7+10+14=31 & 9+10+12=31 & 10+11+12=33 \\
7+9+12=28 & 7+11+12=30 & 9+10+14=33 & 10+11+14=35 \\
7+9+14=30 & 7+11+14=32 & 9+11+12=32 & 10+12+14=36 \\
7+10+11=28 & 7+12+14=33 & 9+11+14=34 & 11+12+14=37
\end{array}
$$

Two of the 20 permutation sums are greater than or equal to 36. Thus the exact p-value for this permutation test is 0.1. Tied values will decrease the number of unique permutations.

When the `saving()` option is supplied, `permute` saves the values of the permutation statistic to the indicated file, in our case, `permdish.dta`. This file can be used to replay the result of `permute`. The `level()` option controls the confidence level of the confidence interval for the permutation p-value. This confidence interval is calculated using `cii` with the reported `n` (number of nonmissing replications) and `c` (the counter for events of significance).

```
. permute using permdish, level(80)
Monte Carlo permutation results                 Number of obs    =          6

      command:  summarize y if treatment
          sum:  r(sum)
  permute var:  y
```

T	T(obs)	c	n	p=c/n	SE(p)	[80% Conf.	Interval]
sum	36	10	100	0.1000	0.0300	.0631113	.1498826

```
Note:  confidence interval is with respect to p=c/n.
Note:  c = #{|T| >= |T(obs)|}
```

◁

▷ Example 2

Consider some fictional data from a randomized complete-block design in which we wish to determine the significance of five treatments.

```
. use http://www.stata-press.com/data/r12/permute1, clear
. list y treatment in 1/10, abbrev(10)
```

	y	treatment
1.	4.407557	1
2.	5.693386	1
3.	7.099699	1
4.	3.12132	1
5.	5.242648	1
6.	4.280349	2
7.	4.508785	2
8.	4.079967	2
9.	5.904368	2
10.	3.010556	2

These data may be analyzed using anova.

```
. anova y treatment subject
```

```
                    Number of obs =      50     R-squared     =  0.3544
                    Root MSE      = .914159     Adj R-squared =  0.1213
```

Source	Partial SS	df	MS	F	Prob > F
Model	16.5182188	13	1.27063221	1.52	0.1574
treatment	13.0226706	9	1.44696341	1.73	0.1174
subject	3.49554813	4	.873887032	1.05	0.3973
Residual	30.0847503	36	.835687509		
Total	46.6029691	49	.951081002		

Suppose that we want to compute the significance of the F statistic for treatment by using permute. All we need to do is write a short program that will save the result of this statistic for permute to use. For example,

```
program panova, rclass
        version 12
        args response fac_intrst fac_other
        anova `response' `fac_intrst' `fac_other'
        return scalar Fmodel = e(F)
        test `fac_intrst'
        return scalar F = r(F)
end
```

Now in panova, test saves the F statistic for the factor of interest in r(F). This is different from e(F), which is the overall model F statistic for the model fit by anova that panova saves in r(Fmodel). In the following example, we use the strata() option so that the treatments are randomly rearranged within each subject. It should not be too surprising that the estimated p-values are equal for this example, because the two F statistics are equivalent when controlling for differences between subjects. However, we would not expect to always get the same p-values every time we reran permute.

```
. set seed 1234
. permute treatment treatmentF=r(F) modelF=e(F), reps(1000) strata(subject)
> saving(permanova) nodots: panova y treatment subject
Monte Carlo permutation results
Number of strata =          5                     Number of obs   =         50
      command:  panova y treatment subject
   treatmentF:  r(F)
       modelF:  e(F)
  permute var:  treatment
```

T	T(obs)	c	n	p=c/n	SE(p)	[95% Conf.	Interval]
treatmentF	1.731465	118	1000	0.1180	0.0102	.0986525	.1396277
modelF	1.520463	118	1000	0.1180	0.0102	.0986525	.1396277

```
Note:  confidence intervals are with respect to p=c/n.
Note:  c = #{|T| >= |T(obs)|}
```

◁

▷ Example 3

As a final example, let's consider estimating the p-value of the Z statistic returned by `ranksum`. Suppose that we collected data from some experiment: `y` is some measure we took on 17 individuals, and `group` identifies the group that an individual belongs to.

```
. use http://www.stata-press.com/data/r12/permute2
. list
```

	group	y
1.	1	6
2.	1	11
3.	1	20
4.	1	2
5.	1	9
6.	1	5
7.	0	2
8.	0	1
9.	0	6
10.	0	0
11.	0	2
12.	0	3
13.	0	3
14.	0	12
15.	0	4
16.	0	1
17.	0	5

Next we analyze the data using `ranksum` and notice that the observed value of the test statistic (saved as `r(z)`) is -2.02 with an approximate p-value of 0.0434.

```
. ranksum y, by(group)
Two-sample Wilcoxon rank-sum (Mann-Whitney) test
      group |      obs    rank sum    expected
------------+---------------------------------
          0 |       11          79          99
          1 |        6          74          54
------------+---------------------------------
   combined |       17         153         153
unadjusted variance       99.00
adjustment for ties       -0.97
                        ---------
adjusted variance         98.03
Ho: y(group==0) = y(group==1)
             z =  -2.020
    Prob > |z| =   0.0434
```

The observed value of the rank-sum statistic is 79, with an expected value (under the null hypothesis of no group effect) of 99. There are 17 observations, so the permutation distribution contains $\binom{17}{6} = 12{,}376$ possible values of the rank-sum statistic if we ignore ties. With ties, we have fewer possible values but still too many to want to count them. Thus we use `permute` with 10,000 replications and see that the Monte Carlo permutation test agrees with the result of the test based on the normal approximation.

```
. set seed 18385766
. permute y z=r(z), reps(10000) nowarn nodots: ranksum y, by(group)
Monte Carlo permutation results                 Number of obs    =         17
      command:  ranksum y, by(group)
            z:  r(z)
  permute var:  y
```

T	T(obs)	c	n	p=c/n	SE(p)	[95% Conf.	Interval]
z	-2.020002	468	10000	0.0468	0.0021	.0427429	.0511236

```
Note:  confidence interval is with respect to p=c/n.
Note:  c = #{|T| >= |T(obs)|}
```

◁

For an application of a permutation test to a problem in epidemiology, see Hayes and Moulton (2009, 190–193).

❑ Technical note

`permute` reports confidence intervals for p to emphasize that it is based on the binomial estimator for proportions. When the variability implied by the confidence interval makes conclusions difficult, you may increase the number of replications to determine more precisely the significance of the test statistic of interest. In other words, the value of p from `permute` will converge to the true permutation p-value as the number of replications gets arbitrarily large. ❑

Saved results

`permute` saves the following in `r()`:

Scalars

`r(N)`	sample size	`r(k_exp)`	number of standard expressions
`r(N_reps)`	number of requested replications	`r(k_eexp)`	number of `_b`/`_se` expressions
`r(level)`	confidence level		

Macros

`r(cmd)`	`permute`	`r(left)`	`left` or empty
`r(command)`	*command* following colon	`r(right)`	`right` or empty
`r(permvar)`	permutation variable	`r(seed)`	initial random-number seed
`r(title)`	title in output	`r(event)`	`T <= T(obs)`, `T >= T(obs)`, or `|T| <= |T(obs)|`
`r(exp#)`	#th expression		

Matrices

`r(b)`	observed statistics	`r(p)`	observed proportions
`r(c)`	count when `r(event)` is true	`r(se)`	standard errors of observed proportions
`r(reps)`	number of nonmissing results	`r(ci)`	confidence intervals of observed proportions

Methods and formulas

`permute` is implemented as an ado-file.

Title

pk — Pharmacokinetic (biopharmaceutical) data

Description

The term pk refers to pharmacokinetic data and the Stata commands, all of which begin with the letters pk, designed to do some of the analyses commonly performed in the pharmaceutical industry. The system is intended for the analysis of pharmacokinetic data, although some of the commands are for general use.

The pk commands are

`pkexamine`	[R] **pkexamine**	Calculate pharmacokinetic measures
`pksumm`	[R] **pksumm**	Summarize pharmacokinetic data
`pkshape`	[R] **pkshape**	Reshape (pharmacokinetic) Latin-square data
`pkcross`	[R] **pkcross**	Analyze crossover experiments
`pkequiv`	[R] **pkequiv**	Perform bioequivalence tests
`pkcollapse`	[R] **pkcollapse**	Generate pharmacokinetic measurement dataset

Remarks

Several types of clinical trials are commonly performed in the pharmaceutical industry. Examples include combination trials, multicenter trials, equivalence trials, and active control trials. For each type of trial, there is an optimal study design for estimating the effects of interest. Currently, the pk system can be used to analyze equivalence trials, which are usually conducted using a crossover design; however, it is possible to use a parallel design and still draw conclusions about equivalence.

Equivalence trials assess bioequivalence between two drugs. Although proving that two drugs behave the same is impossible, the United States Food and Drug Administration believes that if the absorption properties of two drugs are similar, the two drugs will produce similar effects and have similar safety profiles. Generally, the goal of an equivalence trial is to assess the equivalence of a generic drug to an existing drug. This goal is commonly accomplished by comparing a confidence interval about the difference between a pharmacokinetic measurement of two drugs with a confidence limit constructed from U.S. federal regulations. If the confidence interval is entirely within the confidence limit, the drugs are declared bioequivalent. Another approach to assessing bioequivalence is to use the method of interval hypotheses testing. `pkequiv` is used to conduct these tests of bioequivalence.

Several pharmacokinetic measures can be used to ascertain how available a drug is for cellular absorption. The most common measure is the area under the time-versus-concentration curve (AUC). Another common measure of drug availability is the maximum concentration ($C_{\max}$) achieved by the drug during the follow-up period. Stata reports these and other less common measures of drug availability, including the time at which the maximum drug concentration was observed and the duration of the period during which the subject was being measured. Stata also reports the elimination rate, that is, the rate at which the drug is metabolized, and the drug's half-life, that is, the time it takes for the drug concentration to fall to one-half of its maximum concentration.

`pkexamine` computes and reports all the pharmacokinetic measures that Stata produces, including four calculations of the area under the time-versus-concentration curve. The standard area under the curve from 0 to the maximum observed time ($\text{AUC}_{0,t_{\max}}$) is computed using cubic splines or the

trapezoidal rule. Additionally, pkexamine also computes the area under the curve from 0 to infinity by extending the standard time-versus-concentration curve from the maximum observed time by using three different methods. The first method simply extends the standard curve by using a least-squares linear fit through the last few data points. The second method extends the standard curve by fitting a decreasing exponential curve through the last few data points. Finally, the third method extends the curve by fitting a least-squares linear regression line on the log concentration. The mathematical details of these extensions are described in *Methods and formulas* of [R] **pkexamine**.

Data from an equivalence trial may also be analyzed using methods appropriate to the particular study design. When you have a crossover design, pkcross can be used to fit an appropriate ANOVA model. As an aside, a crossover design is simply a restricted Latin square; therefore, pkcross can also be used to analyze any Latin-square design.

There are some practical concerns when dealing with data from equivalence trials. Primarily, the data must be organized in a manner that Stata can use. The pk commands include pkcollapse and pkshape, which are designed to help transform data from a common format to one that is suitable for analysis with Stata.

In the following example, we illustrate several different data formats that are often encountered in pharmaceutical research and describe how these formats can be transformed to formats that can be analyzed with Stata.

▷ Example 1

Assume that we have one subject and are interested in determining the drug profile for that subject. A reasonable experiment would be to give the subject the drug and then measure the concentration of the drug in the subject's blood over a given period. For example, here is a part of a dataset from Chow and Liu (2009, 13):

```
. use http://www.stata-press.com/data/r12/auc
. list, abbrev(14)
```

	id	time	concentration
1.	1	0	0
2.	1	.5	0
3.	1	1	2.8
4.	1	1.5	4.4
5.	1	2	4.4
6.	1	3	4.7
7.	1	4	4.1
8.	1	6	4
9.	1	8	3.6
10.	1	12	3
11.	1	16	2.5
12.	1	24	2
13.	1	32	1.6

Examining these data, we notice that the concentration quickly increases, plateaus for a short period, and then slowly decreases over time. pkexamine is used to calculate the pharmacokinetic measures of interest. pkexamine is explained in detail in [R] **pkexamine**. The output is

```
. pkexamine time conc
                                    Maximum concentration =       4.7
                                  Time of maximum concentration =         3
                                Time of last observation (Tmax) =        32
                                           Elimination rate =    0.0279
                                                  Half life =   24.8503

Area under the curve
```

AUC [0, Tmax]	AUC [0, inf.) Linear of log conc.	AUC [0, inf.) Linear fit	AUC [0, inf.) Exponential fit
85.24	142.603	107.759	142.603

```
Fit based on last 3 points.
```

Clinical trials, however, require that data be collected on more than one subject. There are several ways to enter raw measured data collected on several subjects. It would be reasonable to enter for each subject the drug concentration value at specific points in time. Such data could be

```
id   conc1   conc2   conc3   conc4    conc5   conc6   conc7
 1       0       1       4       7        5       3       1
 2       0       2       6       5        4       3       2
 3       0       1       2       3        5       4       1
```

where `conc1` is the concentration at the first measured time, `conc2` is the concentration at the second measured time, etc. This format requires that each drug concentration measurement be made at the same time on each subject. Another more flexible way to enter the data is to have an observation with three variables for each time measurement on a subject. Each observation would have a subject ID, the time at which the measurement was made, and the corresponding drug concentration at that time. The data would be

```
. use http://www.stata-press.com/data/r12/pkdata
. list id concA time, sepby(id)
```

	id	concA	time
1.	1	0	0
2.	1	3.073403	.5
3.	1	5.188444	1
4.	1	5.898577	1.5
5.	1	5.096378	2
6.	1	6.094085	3
7.	1	5.158772	4
8.	1	5.7065	6

23.	2	6.205004	12
24.	2	5.566165	16
25.	2	3.689007	24
26.	2	3.644063	32
27.	3	0	0
	(output omitted)		
207.	20	4.673281	24
208.	20	3.487347	32

Stata expects the data to be organized in the second form. If your data are organized as described in the first dataset, you will need to use `reshape` to change the data to the second form; see [D] **reshape**. Because the data in the second (or long) format contain information for one drug on several subjects, `pksumm` can be used to produce summary statistics of the pharmacokinetic measurements. The output is

```
. pksumm id time concA
.................
 Summary statistics for the pharmacokinetic measures
                                                  Number of observations =    16
```

Measure	Mean	Median	Variance	Skewness	Kurtosis	p-value

tmax	32.00	32.00	0.00	.	.	.

Until now, we have been concerned with the profile of only one drug. We have characterized the profile of that drug by individual subjects by using `pkexamine` and by a group of subjects by using `pksumm`. The goal of an equivalence trial, however, is to compare two drugs, which we will do in the rest of this example.

For equivalence trials, the study design most often used is the crossover design. For a complete discussion of crossover designs, see Ratkowsky, Evans, and Alldredge (1993).

In brief, crossover designs require that each subject be given both treatments at two different times. The order in which the treatments are applied changes between groups. For example, if we had 20 subjects numbered 1–20, the first 10 would receive treatment A during the first period of the study, and then they would be given treatment B. The second 10 subjects would be given treatment B during the first period of the study, and then they would be given treatment A. Each subject in the study will have four variables that describe the observation: a subject identifier, a sequence identifier that indicates the order of treatment, and two outcome variables, one for each treatment. The outcome variables for each subject are the pharmacokinetic measures. The data must be transformed from a series of measurements on individual subjects to data containing the pharmacokinetic measures for each subject. In Stata parlance, this is referred to as a collapse, which can be done with `pkcollapse`; see [R] **pkcollapse**.

Here is a part of our data:

```
. list, sepby(id)
```

	id	seq	time	concA	concB
1.	1	1	0	0	0
2.	1	1	.5	3.073403	3.712592
3.	1	1	1	5.188444	6.230602
4.	1	1	1.5	5.898577	7.885944
5.	1	1	2	5.096378	9.241735
6.	1	1	3	6.094085	13.10507
7.	1	1	4	5.158772	.169429
8.	1	1	6	5.7065	8.759894
9.	1	1	8	5.272467	7.985409
10.	1	1	12	4.4576	7.740126
11.	1	1	16	5.146423	7.607208
12.	1	1	24	4.947427	7.588428
13.	1	1	32	1.920421	2.791115
14.	2	1	0	0	0
15.	2	1	.5	2.48462	.9209593
16.	2	1	1	4.883569	5.925818
17.	2	1	1.5	7.253442	8.710549
18.	2	1	2	5.849345	10.90552
19.	2	1	3	6.761085	8.429898
20.	2	1	4	4.33839	5.573152
21.	2	1	6	5.04199	6.32341
22.	2	1	8	4.25128	.5251224
23.	2	1	12	6.205004	7.415988
24.	2	1	16	5.566165	6.323938
25.	2	1	24	3.689007	1.133553
26.	2	1	32	3.644063	5.759489
27.	3	1	0	0	0
			(*output omitted*)		
207.	20	2	24	4.673281	6.059818
208.	20	2	32	3.487347	5.213639

This format is similar to the second format described above, except that now we have measurements for two drugs at each time for each subject. We transform these data with `pkcollapse`:

```
. pkcollapse time concA concB, id(id) keep(seq) stat(auc)
.............................
. list, sep(8) abbrev(10)
```

	id	seq	auc_concA	auc_concB
1.	1	1	150.9643	218.5551
2.	2	1	146.7606	133.3201
3.	3	1	160.6548	126.0635
4.	4	1	157.8622	96.17461
5.	5	1	133.6957	188.9038
6.	7	1	160.639	223.6922
7.	8	1	131.2604	104.0139
8.	9	1	168.5186	237.8962
9.	10	2	137.0627	139.7382
10.	12	2	153.4038	202.3942
11.	13	2	163.4593	136.7848
12.	14	2	146.0462	104.5191
13.	15	2	158.1457	165.8654
14.	18	2	147.1977	139.235
15.	19	2	164.9988	166.2391
16.	20	2	145.3823	158.5146

For this example, we chose to use the AUC for two drugs as our pharmacokinetic measure. We could have used any of the measures computed by `pkexamine`. In addition to the AUCs, the dataset also contains a sequence variable for each subject indicating when each treatment was administered.

The data produced by `pkcollapse` are in what Stata calls wide format; that is, there is one observation per subject containing two or more outcomes. To use `pkcross` and `pkequiv`, we need to transform these data to long format. This goal can be accomplished using `pkshape`; see [R] **pkshape**.

Consider the first subject in the dataset. This subject is in sequence one, which means that treatment A was applied during the first period of the study and treatment B was applied in the second period of the study. We need to split the first observation into two observations so that the outcome measure is only in one variable. Also we need two new variables, one indicating the treatment the subject received and another recording the period of the study when the subject received that treatment. We might expect the expansion of the first subject to be

id	sequence	auc	treat	period
1	1	150.9643	A	1
1	1	218.5551	B	2

We see that subject number 1 was in sequence 1, had an AUC of 150.9643 when treatment A was applied in the first period of the study, and had an AUC of 218.5551 when treatment B was applied.

Similarly, the expansion of subject 10 (the first subject in sequence 2) would be

id	sequence	auc	treat	period
10	2	137.0627	B	1
10	2	139.7382	A	2

Here treatment B was applied to the subject during the first period of the study, and treatment A was applied to the subject during the second period of the study.

An additional complication is common in crossover study designs. The treatment applied in the first period of the study might still have some effect on the outcome in the second period. In this example,

each subject was given one treatment followed by another treatment. To get accurate estimates of treatment effects, it is necessary to account for the effect that the first treatment has in the second period of the study. This is called the carryover effect. We must, therefore, have a variable that indicates which treatment was applied in the first treatment period. `pkshape` creates a variable that indicates the carryover effect. For treatments applied during the first treatment period, there will never be a carryover effect. Thus the expanded data created by `pkshape` for subject 1 will be

id	sequence	outcome	treat	period	carry
1	1	150.9643	A	1	0
1	1	218.5551	B	2	A

and the data for subject 10 will be

id	sequence	outcome	treat	period	carry
10	2	137.0627	B	1	0
10	2	139.7382	A	2	B

We `pkshape` the data:

```
. pkshape id seq auc*, order(ab ba)
. sort id sequence period
. list, sep(16)
```

	id	sequence	outcome	treat	carry	period
1.	1	1	150.9643	1	0	1
2.	1	1	218.5551	2	1	2
3.	2	1	146.7606	1	0	1
4.	2	1	133.3201	2	1	2
5.	3	1	160.6548	1	0	1
6.	3	1	126.0635	2	1	2
7.	4	1	157.8622	1	0	1
8.	4	1	96.17461	2	1	2
9.	5	1	133.6957	1	0	1
10.	5	1	188.9038	2	1	2
11.	7	1	160.639	1	0	1
12.	7	1	223.6922	2	1	2
13.	8	1	131.2604	1	0	1
14.	8	1	104.0139	2	1	2
15.	9	1	168.5186	1	0	1
16.	9	1	237.8962	2	1	2
17.	10	2	137.0627	2	0	1
18.	10	2	139.7382	1	2	2
19.	12	2	153.4038	2	0	1
20.	12	2	202.3942	1	2	2
21.	13	2	163.4593	2	0	1
22.	13	2	136.7848	1	2	2
23.	14	2	146.0462	2	0	1
24.	14	2	104.5191	1	2	2
25.	15	2	158.1457	2	0	1
26.	15	2	165.8654	1	2	2
27.	18	2	147.1977	2	0	1
28.	18	2	139.235	1	2	2
29.	19	2	164.9988	2	0	1
30.	19	2	166.2391	1	2	2
31.	20	2	145.3823	2	0	1
32.	20	2	158.5146	1	2	2

As an aside, crossover designs do not require that each subject receive each treatment, but if they do, the crossover design is referred to as a complete crossover design.

The last dataset is organized in a manner that can be analyzed with Stata. To fit an ANOVA model to these data, we can use `anova` or `pkcross`. To conduct equivalence tests, we can use `pkequiv`. This example is further analyzed in [R] **pkcross** and [R] **pkequiv**.

Title

pkcollapse — Generate pharmacokinetic measurement dataset

Syntax

`pkcollapse` *time concentration* [*if*] `,` `id(`*id_var*`)` [*options*]

options	Description
Main	
* `id(`*id_var*`)`	subject ID variable
`stat(`*measures*`)`	create specified *measures*; default is all
`trapezoid`	use trapezoidal rule; default is cubic splines
`fit(#)`	use # points to estimate $\text{AUC}_{0,\infty}$; default is `fit(3)`
`keep(`*varlist*`)`	keep variables in *varlist*
`force`	force collapse
`nodots`	suppress dots during calculation

*`id(`*id_var*`)` is required.

measures	Description
`auc`	area under the concentration-time curve ($\text{AUC}_{0,\infty}$)
`aucline`	area under the concentration-time curve from 0 to ∞ using a linear extension
`aucexp`	area under the concentration-time curve from 0 to ∞ using an exponential extension
`auclog`	area under the log-concentration-time curve extended with a linear fit
`half`	half-life of the drug
`ke`	elimination rate
`cmax`	maximum concentration
`tmax`	time at last concentration
`tomc`	time of maximum concentration

Menu

Statistics > Epidemiology and related > Other > Generate pharmacokinetic measurement dataset

Description

`pkcollapse` generates new variables with the pharmacokinetic summary measures of interest.

`pkcollapse` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

Main

`id(`*id_var*`)` is required and specifies the variable that contains the subject ID over which `pkcollapse` is to operate.

`stat(`*measures*`)` specifies the measures to be generated. The default is to generate all the measures.

`trapezoid` tells Stata to use the trapezoidal rule when calculating the AUC. The default is to use cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.

`fit(#)` specifies the number of points to use in estimating the $\text{AUC}_{0,\infty}$. The default is `fit(3)`, the last three points. This number should be viewed as a minimum; the appropriate number of points will depend on your data.

`keep(`*varlist*`)` specifies the variables to be kept during the collapse. Variables not specified with the `keep()` option will be dropped. When `keep()` is specified, the keep variables are checked to ensure that all values of the variables are the same within *id_var*.

`force` forces the collapse, even when the values of the `keep()` variables are different within the *id_var*.

`nodots` suppresses the display of dots during calculation.

Remarks

`pkcollapse` generates all the summary pharmacokinetic measures.

▷ Example 1

We demonstrate the use of `pkcollapse` with the data described in [R] **pk**. We have drug concentration data on 15 subjects. Each subject is measured at 13 time points over a 32-hour period. Some of the records are

```
. use http://www.stata-press.com/data/r12/pkdata
. list, sep(0)
```

	id	seq	time	concA	concB
1.	1	1	0	0	0
2.	1	1	.5	3.073403	3.712592
3.	1	1	1	5.188444	6.230602
4.	1	1	1.5	5.898577	7.885944
5.	1	1	2	5.096378	9.241735
6.	1	1	3	6.094085	13.10507
			(*output omitted*)		
14.	2	1	0	0	0
15.	2	1	.5	2.48462	.9209593
16.	2	1	1	4.883569	5.925818
17.	2	1	1.5	7.253442	8.710549
18.	2	1	2	5.849345	10.90552
19.	2	1	3	6.761085	8.429898
			(*output omitted*)		
207.	20	2	24	4.673281	6.059818
208.	20	2	32	3.487347	5.213639

Although pksumm allows us to view all the pharmacokinetic measures, we can create a dataset with the measures by using pkcollapse.

```
. pkcollapse time concA concB, id(id) stat(auc) keep(seq)
.............................
. list, sep(8) abbrev(10)
```

	id	seq	auc_concA	auc_concB
1.	1	1	150.9643	218.5551
2.	2	1	146.7606	133.3201
3.	3	1	160.6548	126.0635
4.	4	1	157.8622	96.17461
5.	5	1	133.6957	188.9038
6.	7	1	160.639	223.6922
7.	8	1	131.2604	104.0139
8.	9	1	168.5186	237.8962
9.	10	2	137.0627	139.7382
10.	12	2	153.4038	202.3942
11.	13	2	163.4593	136.7848
12.	14	2	146.0462	104.5191
13.	15	2	158.1457	165.8654
14.	18	2	147.1977	139.235
15.	19	2	164.9988	166.2391
16.	20	2	145.3823	158.5146

The resulting dataset, which we will call pkdata2, contains 1 observation per subject. This dataset is in wide format. If we want to use pkcross or pkequiv, we must transform these data to long format, which we do in the last example of [R] **pkshape**.

◁

Methods and formulas

pkcollapse is implemented as an ado-file.

The statistics generated by pkcollapse are described in [R] **pkexamine**.

Also see

[R] **pk** — Pharmacokinetic (biopharmaceutical) data

Title

pkcross — Analyze crossover experiments

Syntax

`pkcross` *outcome* [*if*] [*in*] [, *options*]

options	Description
Model	
`sequence(`*varname*`)`	sequence variable; default is `sequence(sequence)`
`treatment(`*varname*`)`	treatment variable; default is `treatment(treat)`
`period(`*varname*`)`	period variable; default is `period(period)`
`id(`*varname*`)`	ID variable
`carryover(`*varname*`)`	name of carryover variable; default is `carryover(carry)`
`carryover(none)`	omit carryover effects from model; default is `carryover(carry)`
`model(`*string*`)`	specify the model to fit
`sequential`	estimate sequential instead of partial sums of squares
Parameterization	
`param(3)`	estimate mean and the period, treatment, and sequence effects; assume no carryover effects exist; the default
`param(1)`	estimate mean and the period, treatment, and carryover effects; assume no sequence effects exist
`param(2)`	estimate mean, period and treatment effects, and period-by-treatment interaction; assume no sequence or carryover effects exist
`param(4)`	estimate mean, period and treatment effects, and period-by-treatment interaction; assume no period or crossover effects exist

Menu

Statistics > Epidemiology and related > Other > Analyze crossover experiments

Description

`pkcross` analyzes data from a crossover design experiment. When analyzing pharmaceutical trial data, if the treatment, carryover, and sequence variables are known, the omnibus test for separability of the treatment and carryover effects is calculated.

`pkcross` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

Model

`sequence(`*varname*`)` specifies the variable that contains the sequence in which the treatment was administered. If this option is not specified, `sequence(sequence)` is assumed.

`treatment(`*varname*`)` specifies the variable that contains the treatment information. If this option is not specified, `treatment(treat)` is assumed.

`period(`*varname*`)` specifies the variable that contains the period information. If this option is not specified, `period(period)` is assumed.

`id(`*varname*`)` specifies the variable that contains the subject identifiers. If this option is not specified, `id(id)` is assumed.

`carryover(`*varname*`|`**`none`**`)` specifies the variable that contains the carryover information. If `carry(none)` is specified, the carryover effects are omitted from the model. If this option is not specified, `carryover(carry)` is assumed.

`model(`*string*`)` specifies the model to be fit. For higher-order crossover designs, this option can be useful if you want to fit a model other than the default. However, `anova` (see [R] **anova**) can also be used to fit a crossover model. The default model for higher-order crossover designs is outcome predicted by sequence, period, treatment, and carryover effects. By default, the model statement is `model(sequence period treat carry)`.

`sequential` specifies that sequential sums of squares be estimated.

Parameterization

`param(#)` specifies which of the four parameterizations to use for the analysis of a 2×2 crossover experiment. This option is ignored with higher-order crossover designs. The default is `param(3)`. See the technical note for 2×2 crossover designs for more details.

`param(3)` estimates the overall mean, the period effects, the treatment effects, and the sequence effects, assuming that no carryover effects exist. This is the default parameterization.

`param(1)` estimates the overall mean, the period effects, the treatment effects, and the carryover effects, assuming that no sequence effects exist.

`param(2)` estimates the overall mean, the period effects, the treatment effects, and the period-by-treatment interaction, assuming that no sequence or carryover effects exist.

`param(4)` estimates the overall mean, the sequence effects, the treatment effects, and the sequence-by-treatment interaction, assuming that no period or crossover effects exist. When the sequence by treatment is equivalent to the period effect, this reduces to the third parameterization.

Remarks

`pkcross` is designed to analyze crossover experiments. Use `pkshape` first to reshape your data; see [R] **pkshape**. `pkcross` assumes that the data were reshaped by `pkshape` or are organized in the same manner as produced with `pkshape`. Washout periods are indicated by the number 0. See the technical note in this entry for more information on analyzing 2×2 crossover experiments.

❑ Technical note

The 2×2 crossover design cannot be used to estimate more than four parameters because there are only four pieces of information (the four cell means) collected. `pkcross` uses ANOVA models to analyze the data, so one of the four parameters must be the overall mean of the model, leaving just 3 degrees of freedom to estimate the remaining effects (period, sequence, treatment, and carryover). Thus the model is overparameterized. Estimation of treatment and carryover effects requires the assumption of either no period effects or no sequence effects. Some researchers maintain that it estimating carryover effects at the expense of other effects is a bad idea. This is a limitation of this

design. pkcross implements four parameterizations for this model. They are numbered sequentially from one to four and are described in *Options*.

❑

▷ Example 1

Consider the example data published in Chow and Liu (2009, 71) and described in [R] **pkshape**. We have entered and reshaped the data with pkshape and have variables that identify the subjects, periods, treatments, sequence, and carryover treatment. To compute the ANOVA table, use pkcross:

```
. use http://www.stata-press.com/data/r12/chowliu
. pkshape id seq period1 period2, order(ab ba)
. pkcross outcome
                                        sequence variable = sequence
                                          period variable = period
                                       treatment variable = treat
                                       carryover variable = carry
                                              id variable = id

          Analysis of variance (ANOVA) for a 2x2 crossover study
Source of Variation |      SS       df        MS          F     Prob > F
--------------------+---------------------------------------------------
Intersubjects       |
     Sequence effect |     276.00        1      276.00       0.37     0.5468
           Residuals |   16211.49       22      736.89       4.41     0.0005
--------------------+---------------------------------------------------
Intrasubjects       |
    Treatment effect |      62.79        1       62.79       0.38     0.5463
       Period effect |      35.97        1       35.97       0.22     0.6474
           Residuals |    3679.43       22      167.25
--------------------+---------------------------------------------------
               Total |   20265.68       47
Omnibus measure of separability of treatment and carryover =   29.2893%
```

There is evidence of intersubject variability, but there are no other significant effects. The omnibus test for separability is a measure reflecting the degree to which the study design allows the treatment effects to be estimated independently of the carryover effects. The measure of separability of the treatment and carryover effects indicates approximately 29% separability, which can be interpreted as the degree to which the treatment and carryover effects are orthogonal. This is a characteristic of the design of the study. For a complete discussion, see Ratkowsky, Evans, and Alldredge (1993). Compared to the output in Chow and Liu (2009), the sequence effect is mislabeled as a carryover effect. See Ratkowsky, Evans, and Alldredge (1993, sec. 3.2) for a complete discussion of the mislabeling.

By specifying `param(1)`, we obtain parameterization 1 for this model.

```
. pkcross outcome, param(1)
                                                sequence variable = sequence
                                                  period variable = period
                                               treatment variable = treat
                                               carryover variable = carry
                                                      id variable = id

          Analysis of variance (ANOVA) for a 2x2 crossover study
 Source of Variation | Partial SS   df        MS          F     Prob > F

---------------------+------------------------------------------------------
                 Total |   20265.68   47
Omnibus measure of separability of treatment and carryover =   29.2893%
```

▷ Example 2

Consider the case of a two-treatment, four-sequence, two-period crossover design. This design is commonly referred to as Balaam's design (Balaam 1968). Ratkowsky, Evans, and Alldredge (1993, 140) published the following data from an amantadine trial, originally published by Taka and Armitage (1983):

```
. use http://www.stata-press.com/data/r12/balaam, clear
. list, sep(0)
```

	id	seq	period1	period2	period3
1.	1	-ab	9	8.75	8.75
2.	2	-ab	12	10.5	9.75
3.	3	-ab	17	15	18.5
4.	4	-ab	21	21	21.5
5.	1	-ba	23	22	18
6.	2	-ba	15	15	13
7.	3	-ba	13	14	13.75
8.	4	-ba	24	22.75	21.5
9.	5	-ba	18	17.75	16.75
10.	1	-aa	14	12.5	14
11.	2	-aa	27	24.25	22.5
12.	3	-aa	19	17.25	16.25
13.	4	-aa	30	28.25	29.75
14.	1	-bb	21	20	19.51
15.	2	-bb	11	10.5	10
16.	3	-bb	20	19.5	20.75
17.	4	-bb	25	22.5	23.5

The sequence identifier must be a string with zeros to indicate washout or baseline periods, or a number. If the sequence identifier is numeric, the `order` option must be specified with `pkshape`. If the sequence identifier is a string, `pkshape` will create sequence, period, and treatment identifiers without the `order` option. In this example, the dash is used to indicate a baseline period, which is an invalid code for this purpose. As a result, the data must be encoded; see [D] **encode**.

```
. encode seq, gen(num_seq)
. pkshape id num_seq period1 period2 period3, order(0aa 0ab 0ba 0bb)
. pkcross outcome, se
                                                sequence variable = sequence
                                                  period variable = period
                                               treatment variable = treat
                                               carryover variable = carry
                                                      id variable = id
```

Analysis of variance (ANOVA) for a crossover study

Source of Variation	SS	df	MS	F	Prob > F
Intersubjects					
Sequence effect	285.82	3	95.27	1.01	0.4180
Residuals	1221.49	13	93.96	59.96	0.0000
Intrasubjects					
Period effect	15.13	2	7.56	6.34	0.0048
Treatment effect	8.48	1	8.48	8.86	0.0056
Carryover effect	0.11	1	0.11	0.12	0.7366
Residuals	29.56	30	0.99		
Total	1560.59	50			

```
Omnibus measure of separability of treatment and carryover =   64.6447%
```

In this example, the sequence specifier used dashes instead of zeros to indicate a baseline period during which no treatment was given. For `pkcross` to work, we need to encode the string sequence variable and then use the `order` option with `pkshape`. A word of caution: `encode` does not necessarily choose the first sequence to be sequence 1, as in this example. Always double-check the sequence numbering when using `encode`.

◁

Example 3

Continuing with the example from [R] **pkshape**, we fit an ANOVA model.

```
. use http://www.stata-press.com/data/r12/pkdata3, clear
. list, sep(8)
```

	id	sequence	outcome	treat	carry	period
1.	1	1	150.9643	A	0	1
2.	2	1	146.7606	A	0	1
3.	3	1	160.6548	A	0	1
4.	4	1	157.8622	A	0	1
5.	5	1	133.6957	A	0	1
6.	7	1	160.639	A	0	1
7.	8	1	131.2604	A	0	1
8.	9	1	168.5186	A	0	1
9.	10	2	137.0627	B	0	1
10.	12	2	153.4038	B	0	1
11.	13	2	163.4593	B	0	1
12.	14	2	146.0462	B	0	1
13.	15	2	158.1457	B	0	1
14.	18	2	147.1977	B	0	1
15.	19	2	164.9988	B	0	1
16.	20	2	145.3823	B	0	1
17.	1	1	218.5551	B	A	2
18.	2	1	133.3201	B	A	2
19.	3	1	126.0635	B	A	2
20.	4	1	96.17461	B	A	2
21.	5	1	188.9038	B	A	2
22.	7	1	223.6922	B	A	2
23.	8	1	104.0139	B	A	2
24.	9	1	237.8962	B	A	2
25.	10	2	139.7382	A	B	2
26.	12	2	202.3942	A	B	2
27.	13	2	136.7848	A	B	2
28.	14	2	104.5191	A	B	2
29.	15	2	165.8654	A	B	2
30.	18	2	139.235	A	B	2
31.	19	2	166.2391	A	B	2
32.	20	2	158.5146	A	B	2

The ANOVA model is fit using pkcross:

```
. pkcross outcome
                                                sequence variable = sequence
                                                  period variable = period
                                               treatment variable = treat
                                               carryover variable = carry
                                                     id variable = id
```

Analysis of variance (ANOVA) for a 2x2 crossover study

Source of Variation	SS	df	MS	F	Prob > F
Intersubjects					
Sequence effect	378.04	1	378.04	0.29	0.5961
Residuals	17991.26	14	1285.09	1.40	0.2691
Intrasubjects					
Treatment effect	455.04	1	455.04	0.50	0.4931
Period effect	419.47	1	419.47	0.46	0.5102
Residuals	12860.78	14	918.63		
Total	32104.59	31			

Omnibus measure of separability of treatment and carryover = 29.2893%

◁

▷ Example 4

Consider the case of a six-treatment crossover trial in which the squares are not variance balanced. The following dataset is from a partially balanced crossover trial published by Patterson and Lucas (1962) and reproduced in Ratkowsky, Evans, and Alldredge (1993, 231):

```
. use http://www.stata-press.com/data/r12/nobalance
. list, sep(4)
```

	cow	seq	period1	period2	period3	period4	block
1.	1	adbe	38.7	37.4	34.3	31.3	1
2.	2	baed	48.9	46.9	42	39.6	1
3.	3	ebda	34.6	32.3	28.5	27.1	1
4.	4	deab	35.2	33.5	28.4	25.1	1
5.	1	dafc	32.9	33.1	27.5	25.1	2
6.	2	fdca	30.4	29.5	26.7	23.1	2
7.	3	cfad	30.8	29.3	26.4	23.2	2
8.	4	acdf	25.7	26.1	23.4	18.7	2
9.	1	efbc	25.4	26	23.9	19.9	3
10.	2	becf	21.8	23.9	21.7	17.6	3
11.	3	fceb	21.4	22	19.4	16.6	3
12.	4	cbfe	22.8	21	18.6	16.1	3

When there is no variance balance in the design, a square or blocking variable is needed to indicate in which treatment cell a sequence was observed, but the mechanical steps are the same.

```
. pkshape cow seq period1 period2 period3 period4
. pkcross outcome, model(block cow|block period|block treat carry) se
```

```
                    Number of obs =      48     R-squared     =  0.9965
                    Root MSE      = .740408     Adj R-squared =  0.9903
```

Source	Seq. SS	df	MS	F	Prob > F
Model	2650.1331	30	88.3377701	161.14	0.0000
block	1607.01128	2	803.505642	1465.71	0.0000
cow|block	628.706274	9	69.8562527	127.43	0.0000
period|block	408.031253	9	45.3368059	82.70	0.0000
treat	2.50000057	5	.500000114	0.91	0.4964
carry	3.88428906	5	.776857812	1.42	0.2680
Residual	9.31945887	17	.548203463		
Total	2659.45256	47	56.584097		

When the model statement is used and the omnibus measure of separability is desired, specify the variables in the `treatment()`, `carryover()`, and `sequence()` options to `pkcross`. ◁

Methods and formulas

`pkcross` is implemented as an ado-file.

`pkcross` uses ANOVA to fit models for crossover experiments; see [R] **anova**.

The omnibus measure of separability is

$$S = 100(1 - V)\%$$

where V is Cramér's V and is defined as

$$V = \left\{ \frac{\frac{\chi^2}{N}}{\min(r-1, c-1)} \right\}^{\frac{1}{2}}$$

The χ^2 is calculated as

$$\chi^2 = \sum_i \sum_j \left\{ \frac{(O_{ij} - E_{ij})^2}{E_{ij}} \right\}$$

where O and E are the observed and expected counts in a table of the number of times each treatment is followed by the other treatments.

Title

pkequiv — Perform bioequivalence tests

Syntax

`pkequiv` *outcome treatment period sequence id* [*if*] [*in*] [`,` *options*]

options	Description
Options	
`compare(`*string*`)`	compare the two specified values of the treatment variable
`limit(#)`	equivalence limit (between 0.10 and 0.99); default is 0.2
`level(#)`	set confidence level; default is `level(90)`
`fieller`	calculate confidence interval by Fieller's theorem
`symmetric`	calculate symmetric equivalence interval
`anderson`	Anderson and Hauck hypothesis test for bioequivalence
`tost`	two one-sided hypothesis tests for bioequivalence
`noboot`	do not estimate probability that CI lies within confidence limits

Menu

Statistics > Epidemiology and related > Other > Bioequivalence tests

Description

`pkequiv` performs bioequivalence testing for two treatments. By default, `pkequiv` calculates a standard confidence interval symmetric about the difference between the two treatment means. `pkequiv` also calculates confidence intervals symmetric about zero and intervals based on Fieller's theorem. Also, `pkequiv` can perform interval hypothesis tests for bioequivalence.

`pkequiv` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

Options

`compare(`*string*`)` specifies the two treatments to be tested for equivalence. Sometimes there may be more than two treatments, but the equivalence can be determined only between any two treatments.

`limit(#)` specifies the equivalence limit. The default is 0.2. The equivalence limit can be changed only symmetrically; that is, it is not possible to have a 0.15 lower limit and a 0.2 upper limit in the same test.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(90)`. This setting is not controlled by the `set level` command.

`fieller` specifies that an equivalence interval based on Fieller's theorem be calculated.

`symmetric` specifies that a symmetric equivalence interval be calculated.

`anderson` specifies that the Anderson and Hauck (1983) hypothesis test for bioequivalence be computed. This option is ignored when calculating equivalence intervals based on Fieller's theorem or when calculating a confidence interval that is symmetric about zero.

`tost` specifies that the two one-sided hypothesis tests for bioequivalence be computed. This option is ignored when calculating equivalence intervals based on Fieller's theorem or when calculating a confidence interval that is symmetric about zero.

`noboot` prevents the estimation of the probability that the confidence interval lies within the confidence limits. If this option is not specified, this probability is estimated by resampling the data.

Remarks

`pkequiv` is designed to conduct tests for bioequivalence based on data from a crossover experiment. `pkequiv` requires that the user specify the *outcome*, *treatment*, *period*, *sequence*, and *id* variables. The data must be in the same format as that produced by `pkshape`; see [R] **pkshape**.

Example 1

Continuing with example 4 from [R] **pkshape**, we will conduct equivalence testing.

```
. use http://www.stata-press.com/data/r12/pkdata3
. list, sep(4)
```

	id	sequence	outcome	treat	carry	period
1.	1	1	150.9643	A	0	1
2.	2	1	146.7606	A	0	1
3.	3	1	160.6548	A	0	1
4.	4	1	157.8622	A	0	1
5.	5	1	133.6957	A	0	1
6.	7	1	160.639	A	0	1
7.	8	1	131.2604	A	0	1
8.	9	1	168.5186	A	0	1
9.	10	2	137.0627	B	0	1
10.	12	2	153.4038	B	0	1
11.	13	2	163.4593	B	0	1
12.	14	2	146.0462	B	0	1
13.	15	2	158.1457	B	0	1
14.	18	2	147.1977	B	0	1
15.	19	2	164.9988	B	0	1
16.	20	2	145.3823	B	0	1
17.	1	1	218.5551	B	A	2
18.	2	1	133.3201	B	A	2
19.	3	1	126.0635	B	A	2
20.	4	1	96.17461	B	A	2
21.	5	1	188.9038	B	A	2
22.	7	1	223.6922	B	A	2
23.	8	1	104.0139	B	A	2
24.	9	1	237.8962	B	A	2
25.	10	2	139.7382	A	B	2
26.	12	2	202.3942	A	B	2
27.	13	2	136.7848	A	B	2
28.	14	2	104.5191	A	B	2
29.	15	2	165.8654	A	B	2
30.	18	2	139.235	A	B	2
31.	19	2	166.2391	A	B	2
32.	20	2	158.5146	A	B	2

Now we can conduct a bioequivalence test between `treat` $= A$ and `treat` $= B$.

```
. set seed 1
. pkequiv outcome treat period seq id
      Classic confidence interval for bioequivalence
------------------------------------------------------------------------------
                    [equivalence limits]        [    test limits   ]
------------------------------------------------------------------------------
     difference:   -30.296        30.296        -11.332        26.416
          ratio:       80%          120%         92.519%      117.439%
------------------------------------------------------------------------------
probability test limits are within equivalence limits =    0.6410
note: reference treatment = 1
```

The default output for `pkequiv` shows a confidence interval for the difference of the means (test limits), the ratio of the means, and the federal equivalence limits. The classic confidence interval can be constructed around the difference between the average measure of effect for the two drugs or around the ratio of the average measure of effect for the two drugs. `pkequiv` reports both the difference measure and the ratio measure. For these data, U.S. federal government regulations state that the confidence interval for the difference must be entirely contained within the range $[-30.296, 30.296]$ and between 80% and 120% for the ratio. Here the test limits are within the equivalence limits. Although the test limits are inside the equivalence limits, there is only a 64% assurance that the observed confidence interval will be within the equivalence limits in the long run. This is an interesting case because, although this sample shows bioequivalence, the evaluation of the long-run performance indicates possible problems. These fictitious data were generated with high intersubject variability, which causes poor long-run performance.

If we conduct a bioequivalence test with the data published in Chow and Liu (2009, 71), which we introduced in [R] **pk** and fully described in [R] **pkshape**, we observe that the probability that the test limits are within the equivalence limits is high.

```
. use http://www.stata-press.com/data/r12/chowliu2
. set seed 1
. pkequiv outcome treat period seq id
      Classic confidence interval for bioequivalence
------------------------------------------------------------------------------
                    [equivalence limits]        [    test limits   ]
------------------------------------------------------------------------------
     difference:   -16.512        16.512         -8.698         4.123
          ratio:       80%          120%         89.464%      104.994%
------------------------------------------------------------------------------
probability test limits are within equivalence limits =    0.9980
note: reference treatment = 1
```

For these data, the test limits are well within the equivalence limits, and the probability that the test limits are within the equivalence limits is 99.8%.

◁

▷ Example 2

We compute a confidence interval that is symmetric about zero:

```
. pkequiv outcome treat period seq id, symmetric
      Westlake's symmetric confidence interval for bioequivalence
      ──────────────────────────────────────────────────────────────
                         [Equivalence limits]       [    Test mean   ]
      ──────────────────────────────────────────────────────────────
      Test formulation:     75.145    89.974               80.272
      ──────────────────────────────────────────────────────────────
      note: reference treatment = 1
```

The reported equivalence limit is constructed symmetrically about the reference mean, which is equivalent to constructing a confidence interval symmetric about zero for the difference in the two drugs. In the output above, we see that the test formulation mean of 80.272 is within the equivalence limits, indicating that the test drug is bioequivalent to the reference drug.

`pkequiv` displays interval hypothesis tests of bioequivalence if you specify the `tost` or the `anderson` option, or both. For example,

```
. set seed 1
. pkequiv outcome treat period seq id, tost anderson
      Classic confidence interval for bioequivalence
      ──────────────────────────────────────────────────────────────
                         [equivalence limits]        [    test limits   ]
      ──────────────────────────────────────────────────────────────
           difference:   -16.512       16.512         -8.698        4.123
                ratio:       80%         120%         89.464%     104.994%
      ──────────────────────────────────────────────────────────────
      probability test limits are within equivalence limits =    0.9980
      Schuirmann's two one-sided tests
      ──────────────────────────────────────────────────────────────
      upper test statistic =    -5.036                   p-value =     0.000
      lower test statistic =     3.810                   p-value =     0.001
      Anderson and Hauck's test
      ──────────────────────────────────────────────────────────────
      noncentrality parameter =     4.423
              test statistic =    -0.613      empirical p-value =    0.0005
      note: reference treatment = 1
```

Both of Schuirmann's one-sided tests are highly significant, suggesting that the two drugs are bioequivalent. A similar conclusion is drawn from the Anderson and Hauck test of bioequivalence. ◁

Saved results

`pkequiv` saves the following in `r()`:

Scalars

`r(stddev)`	pooled-sample standard deviation of period differences from both sequences
`r(uci)`	upper confidence interval for a classic interval
`r(lci)`	lower confidence interval for a classic interval
`r(delta)`	delta value used in calculating a symmetric confidence interval
`r(u3)`	upper confidence interval for Fieller's confidence interval
`r(l3)`	lower confidence interval for Fieller's confidence interval

Methods and formulas

pkequiv is implemented as an ado-file.

The lower confidence interval for the difference in the two treatments for the classic shortest confidence interval is

$$L_1 = \left(\overline{Y}_T - \overline{Y}_R\right) - t_{(\alpha,n_1+n_2-2)}\widehat{\sigma}_d\sqrt{\frac{1}{n_1}+\frac{1}{n_2}}$$

The upper limit is

$$U_1 = \left(\overline{Y}_T - \overline{Y}_R\right) + t_{(\alpha,n_1+n_2-2)}\widehat{\sigma}_d\sqrt{\frac{1}{n_1}+\frac{1}{n_2}}$$

The limits for the ratio measure are

$$L_2 = \left(\frac{L_1}{\overline{Y}_R}+1\right)100\%$$

and

$$U_2 = \left(\frac{U_1}{\overline{Y}_R}+1\right)100\%$$

where $\overline{Y}_T$ is the mean of the test formulation of the drug, $\overline{Y}_R$ is the mean of the reference formulation of the drug, and $t_{(\alpha,n_1+n_2-2)}$ is the t distribution with n_1+n_2-2 degrees of freedom. $\widehat{\sigma}_d$ is the pooled sample variance of the period differences from both sequences, defined as

$$\widehat{\sigma}_d = \frac{1}{n_1+n_2-2}\sum_{k=1}^{2}\sum_{i=1}^{n_k}\left(d_{ik}-\overline{d}_{.k}\right)^2$$

The upper and lower limits for the symmetric confidence interval are $\overline{Y}_R+\Delta$ and $\overline{Y}_R-\Delta$, where

$$\Delta = k_1\widehat{\sigma}_d\sqrt{\frac{1}{n_1}+\frac{1}{n_2}} - \left(\overline{Y}_T - \overline{Y}_R\right)$$

and (simultaneously)

$$\Delta = -k_2\widehat{\sigma}_d\sqrt{\frac{1}{n_1}+\frac{1}{n_2}} + 2\left(\overline{Y}_T - \overline{Y}_R\right)$$

and k_1 and k_2 are computed iteratively to satisfy the above equalities and the condition

$$\int_{k_1}^{k_2} f(t)dt = 1-2\alpha$$

where $f(t)$ is the probability density function of the t distribution with n_1+n_2-2 degrees of freedom.

See Chow and Liu (2009, 88–92) for details about calculating the confidence interval based on Fieller's theorem.

The two test statistics for the two one-sided tests of equivalence are

$$T_L = \frac{\left(\overline{Y}_T - \overline{Y}_R\right) - \theta_L}{\widehat{\sigma}_d\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

and

$$T_U = \frac{\left(\overline{Y}_T - \overline{Y}_R\right) - \theta_U}{\widehat{\sigma}_d\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

where $-\theta_L = \theta_U$ and are the regulated confidence limits.

The logic of the Anderson and Hauck test is tricky; see Chow and Liu (2009) for a complete explanation. However, the test statistic is

$$T_{AH} = \frac{\left(\overline{Y}_T - \overline{Y}_R\right) - \left(\frac{\theta_L + \theta_U}{2}\right)}{\widehat{\sigma}_d\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

and the noncentrality parameter is estimated by

$$\widehat{\delta} = \frac{\theta_U - \theta_L}{2\widehat{\sigma}_d\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

The empirical p-value is calculated as

$$p = F_t\left(|T_{AH}| - \widehat{\delta}\right) - F_t\left(-|T_{AH}| - \widehat{\delta}\right)$$

where F_t is the cumulative distribution function of the t distribution with $n_1 + n_2 - 2$ degrees of freedom.

Title

pkexamine — Calculate pharmacokinetic measures

Syntax

`pkexamine` *time concentration* [*if*] [*in*] [, *options*]

options	Description
Main	
`fit(#)`	use # points to estimate $AUC_{0,\infty}$; default is `fit(3)`
`trapezoid`	use trapezoidal rule; default is cubic splines
`graph`	graph the AUC
`line`	graph the linear extension
`log`	graph the log extension
`exp(#)`	plot the exponential fit for the $AUC_{0,\infty}$
AUC plot	
cline_options	affect rendition of plotted points connected by lines
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

`by` is allowed; see [D] **by**.

Menu

Statistics > Epidemiology and related > Other > Pharmacokinetic measures

Description

`pkexamine` calculates pharmacokinetic measures from time-and-concentration subject-level data. `pkexamine` computes and displays the maximum measured concentration, the time at the maximum measured concentration, the time of the last measurement, the elimination time, the half-life, and the area under the concentration-time curve (AUC). Three estimates of the area under the concentration-time curve from 0 to infinity ($AUC_{0,\infty}$) are also calculated.

`pkexamine` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

Main

`fit(#)` specifies the number of points, counting back from the last measurement, to use in fitting the extension to estimate the $\text{AUC}_{0,\infty}$. The default is `fit(3)`, or the last three points. This value should be viewed as a minimum; the appropriate number of points will depend on your data.

`trapezoid` specifies that the trapezoidal rule be used to calculate the AUC. The default is cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.

`graph` tells `pkexamine` to graph the concentration-time curve.

`line` and `log` specify the estimates of the $\text{AUC}_{0,\infty}$ to display when graphing the $\text{AUC}_{0,\infty}$. These options are ignored, unless they are specified with the `graph` option.

`exp(#)` specifies that the exponential fit for the $\text{AUC}_{0,\infty}$ be plotted. You must specify the maximum time value to which you want to plot the curve, and this time value must be greater than the maximum time measurement in the data. If you specify 0, the curve will be plotted to the point at which the linear extension would cross the x axis. This option is not valid with the `line` or `log` option and is ignored, unless the `graph` option is also specified.

AUC plot

cline_options affect the rendition of the plotted points connected by lines; see [G-3] ***cline_options***.

marker_options specify the look of markers. This look includes the marker symbol, the marker size, and its color and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

`pkexamine` computes summary statistics for a given patient in a pharmacokinetic trial. If `by` *idvar*`:` is specified, statistics will be displayed for each subject in the data.

▷ Example 1

Chow and Liu (2009, 13) present data on a study examining primidone concentrations versus time for a subject over a 32-hour period after dosing.

```
. use http://www.stata-press.com/data/r12/auc
. list, abbrev(14)
```

	id	time	concentration
1.	1	0	0
2.	1	.5	0
3.	1	1	2.8
4.	1	1.5	4.4
5.	1	2	4.4
6.	1	3	4.7
7.	1	4	4.1
8.	1	6	4
9.	1	8	3.6
10.	1	12	3
11.	1	16	2.5
12.	1	24	2
13.	1	32	1.6

We use `pkexamine` to produce the summary statistics:

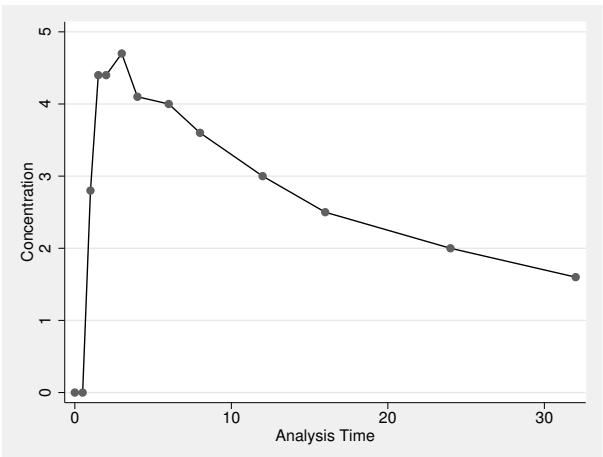
```
. pkexamine time conc, graph
```

```
                        Maximum concentration =       4.7
                  Time of maximum concentration =         3
Time of last observation (Tmax) =        32
                        Elimination rate =    0.0279
                               Half life =   24.8503
```

Area under the curve

AUC [0, Tmax]	AUC [0, inf.) Linear of log conc.	AUC [0, inf.) Linear fit	AUC [0, inf.) Exponential fit
85.24	142.603	107.759	142.603

Fit based on last 3 points.



The maximum concentration of 4.7 occurs at time 3, and the time of the last observation (Tmax) is 32. In addition to the AUC, which is calculated from 0 to the maximum value of `time`, `pkexamine` also reports the area under the curve, computed by extending the curve with each of three methods: a linear fit to the log of the concentration, a linear regression line, and a decreasing exponential regression line. See *Methods and formulas* for details on these three methods.

By default, all extensions to the AUC are based on the last three points. Looking at the graph for these data, it seems more appropriate to use the last seven points to estimate the $\text{AUC}_{0,\infty}$:

```
. pkexamine time conc, fit(7)
```

```
                                  Maximum concentration =       4.7
                              Time of maximum concentration =         3
                            Time of last observation (Tmax) =        32
                                        Elimination rate =    0.0349
                                               Half life =   19.8354

Area under the curve
```

AUC [0, Tmax]	AUC [0, inf.) Linear of log conc.	AUC [0, inf.) Linear fit	AUC [0, inf.) Exponential fit
85.24	131.027	96.805	129.181

```
Fit based on last 7 points.
```

This approach decreased the estimate of the $\text{AUC}_{0,\infty}$ for all extensions. To see a graph of the $\text{AUC}_{0,\infty}$ using a linear extension, specify the `graph` and `line` options.

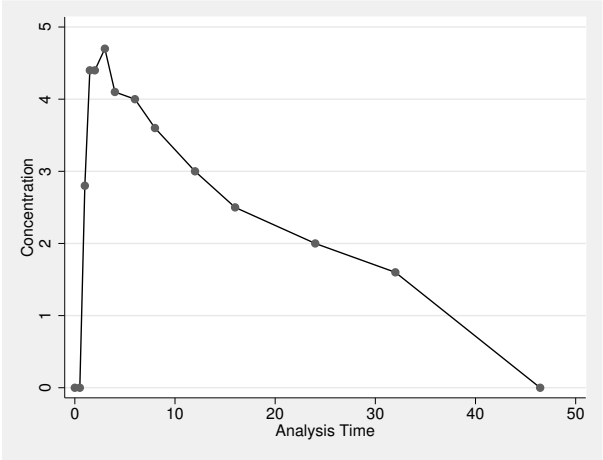
```
. pkexamine time conc, fit(7) graph line
```

```
                                  Maximum concentration =       4.7
                              Time of maximum concentration =         3
                            Time of last observation (Tmax) =        32
                                        Elimination rate =    0.0349
                                               Half life =   19.8354

Area under the curve
```

AUC [0, Tmax]	AUC [0, inf.) Linear of log conc.	AUC [0, inf.) Linear fit	AUC [0, inf.) Exponential fit
85.24	131.027	96.805	129.181

```
Fit based on last 7 points.
```



Saved results

`pkexamine` saves the following in `r()`:

Scalars

`r(auc)`	area under the concentration curve
`r(half)`	half-life of the drug
`r(ke)`	elimination rate
`r(tmax)`	time at last concentration measurement
`r(cmax)`	maximum concentration
`r(tomc)`	time of maximum concentration
`r(auc_line)`	$\text{AUC}_{0,\infty}$ estimated with a linear fit
`r(auc_exp)`	$\text{AUC}_{0,\infty}$ estimated with an exponential fit
`r(auc_ln)`	$\text{AUC}_{0,\infty}$ estimated with a linear fit of the natural log

Methods and formulas

`pkexamine` is implemented as an ado-file.

Let i index the observations sorted by time, let k be the number of observations, and let f be the number of points specified in the `fit(#)` option.

The $\text{AUC}_{0,t_{\max}}$ is defined as

$$\text{AUC}_{0,t_{\max}} = \int_0^{t_{\max}} C_t dt$$

where C_t is the concentration at time t. By default, the integral is calculated numerically using cubic splines. However, if the trapezoidal rule is used, the $\text{AUC}_{0,t_{\max}}$ is given as

$$\text{AUC}_{0,t_{\max}} = \sum_{i=2}^{k} \frac{C_{i-1} + C_i}{2} (t_i - t_{i-1})$$

The $\text{AUC}_{0,\infty}$ is the $\text{AUC}_{0,t_{\max}}$ + $\text{AUC}_{t_{\max},\infty}$, or

$$\text{AUC}_{0,\infty} = \int_0^{t_{\max}} C_t dt + \int_{t_{\max}}^{\infty} C_t dt$$

When using the linear extension to the $\text{AUC}_{0,t_{\max}}$, the integration is cut off when the line crosses the x axis. The log extension is a linear extension on the log concentration scale. The area for the exponential extension is

$$\text{AUC}_{0,\infty} = \int_{t_{\max}}^{\infty} e^{-(\beta_0 + t\beta_1)} dt = -\frac{e^{-(\beta_0 + t_{\max}\beta_1)}}{\beta_1}$$

The elimination rate K_{eq} is the negative of the slope from a linear regression of log concentration on time fit to the number of points specified in the `fit(#)` option:

$$K_{\text{eq}} = -\frac{\sum_{i=k-f+1}^{k} \left(t_i - \bar{t}\right)\left(\ln C_i - \overline{\ln C}\right)}{\sum_{i=k-f+1}^{k} \left(t_i - \bar{t}\right)^2}$$

The half-life is

$$t_{\text{half}} = \frac{\ln 2}{K_{\text{eq}}}$$

[R] **pk** — Pharmacokinetic (biopharmaceutical) data

Title

pkshape — Reshape (pharmacokinetic) Latin-square data

Syntax

`pkshape` *id sequence period1 period2* [*period list*] [`,` *options*]

options	Description
`order(`*string*`)`	apply treatments in specified order
`outcome(`*newvar*`)`	name for outcome variable; default is `outcome(outcome)`
`treatment(`*newvar*`)`	name for treatment variable; default is `treatment(treat)`
`carryover(`*newvar*`)`	name for carryover variable; default is `carryover(carry)`
`sequence(`*newvar*`)`	name for sequence variable; default is `sequence(sequence)`
`period(`*newvar*`)`	name for period variable; default is `period(period)`

Menu

Statistics > Epidemiology and related > Other > Reshape pharmacokinetic latin-square data

Description

`pkshape` reshapes the data for use with `anova`, `pkcross`, and `pkequiv`; see [R] **anova**, [R] **pkcross**, and [R] **pkequiv**. Latin-square and crossover data are often organized in a manner that cannot be analyzed easily with Stata. `pkshape` reorganizes the data in memory for use in Stata.

`pkshape` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

`order(`*string*`)` specifies the order in which treatments were applied. If the `sequence()` specifier is a string variable that specifies the order, this option is not necessary. Otherwise, `order()` specifies how to generate the treatment and carryover variables. Any string variable can be used to specify the order. For crossover designs, any washout periods can be indicated with the number 0.

`outcome(`*newvar*`)` specifies the name for the outcome variable in the reorganized data. By default, `outcome(outcome)` is used.

`treatment(`*newvar*`)` specifies the name for the treatment variable in the reorganized data. By default, `treatment(treat)` is used.

`carryover(`*newvar*`)` specifies the name for the carryover variable in the reorganized data. By default, `carryover(carry)` is used.

`sequence(`*newvar*`)` specifies the name for the sequence variable in the reorganized data. By default, `sequence(sequence)` is used.

`period(`*newvar*`)` specifies the name for the period variable in the reorganized data. By default, `period(period)` is used.

Remarks

Often data from a Latin-square experiment are naturally organized in a manner that Stata cannot manage easily. `pkshape` reorganizes Latin-square data so that they can be used with `anova` (see [R] **anova**) or any pk command. This includes the classic 2×2 crossover design commonly used in pharmaceutical research, as well as many other Latin-square designs.

▷ Example 1

Consider the example data published in Chow and Liu (2009, 71). There are 24 patients, 12 in each sequence. Sequence 1 consists of the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. The measurements reported are the $\text{AUC}_{0-t_{\max}}$ for each patient and for each period.

```
. use http://www.stata-press.com/data/r12/chowliu
. list, sep(4)
```

	id	seq	period1	period2
1.	1	1	74.675	73.675
2.	4	1	96.4	93.25
3.	5	1	101.95	102.125
4.	6	1	79.05	69.45
5.	11	1	79.05	69.025
6.	12	1	85.95	68.7
7.	15	1	69.725	59.425
8.	16	1	86.275	76.125
9.	19	1	112.675	114.875
10.	20	1	99.525	116.25
11.	23	1	89.425	64.175
12.	24	1	55.175	74.575
13.	2	2	74.825	37.35
14.	3	2	86.875	51.925
15.	7	2	81.675	72.175
16.	8	2	92.7	77.5
17.	9	2	50.45	71.875
18.	10	2	66.125	94.025
19.	13	2	122.45	124.975
20.	14	2	99.075	85.225
21.	17	2	86.35	95.925
22.	18	2	49.925	67.1
23.	21	2	42.7	59.425
24.	22	2	91.725	114.05

Because the outcome for one person is in two different variables, the treatment that was applied to an individual is a function of the period and the sequence. To analyze this treatment using `anova`, all the outcomes must be in one variable, and each covariate must be in its own variable. To reorganize these data, use `pkshape`:

```
. pkshape id seq period1 period2, order(ab ba)
. sort seq id treat
```

```
. list, sep(8)
```

	id	sequence	outcome	treat	carry	period
1.	1	1	74.675	1	0	1
2.	1	1	73.675	2	1	2
3.	4	1	96.4	1	0	1
4.	4	1	93.25	2	1	2
5.	5	1	101.95	1	0	1
6.	5	1	102.125	2	1	2
7.	6	1	79.05	1	0	1
8.	6	1	69.45	2	1	2
9.	11	1	79.05	1	0	1
10.	11	1	69.025	2	1	2
11.	12	1	85.95	1	0	1
12.	12	1	68.7	2	1	2

33.	9	2	71.875	1	2	2
34.	9	2	50.45	2	0	1
35.	10	2	94.025	1	2	2
36.	10	2	66.125	2	0	1
37.	13	2	124.975	1	2	2
38.	13	2	122.45	2	0	1
39.	14	2	85.225	1	2	2
40.	14	2	99.075	2	0	1
41.	17	2	95.925	1	2	2
42.	17	2	86.35	2	0	1
43.	18	2	67.1	1	2	2
44.	18	2	49.925	2	0	1
45.	21	2	59.425	1	2	2
46.	21	2	42.7	2	0	1
47.	22	2	114.05	1	2	2
48.	22	2	91.725	2	0	1

Now the data are organized into separate variables that indicate each factor level for each of the covariates, so the data may be used with `anova` or `pkcross`; see [R] **anova** and [R] **pkcross**.

◁

Example 2

Consider the study of background music on bank teller productivity published in Kutner et al. (2005). The data are

Week	Monday	Tuesday	Wednesday	Thursday	Friday
1	18(D)	17(C)	14(A)	21(B)	17(E)
2	13(C)	34(B)	21(E)	16(A)	15(D)
3	7(A)	29(D)	32(B)	27(E)	13(C)
4	17(E)	13(A)	24(C)	31(D)	25(B)
5	21(B)	26(E)	26(D)	31(C)	7(A)

The numbers are the productivity scores, and the letters represent the treatment. We entered the data into Stata:

```
. use http://www.stata-press.com/data/r12/music, clear
. list
```

	id	seq	day1	day2	day3	day4	day5
1.	1	dcabe	18	17	14	21	17
2.	2	cbead	13	34	21	16	15
3.	3	adbec	7	29	32	27	13
4.	4	eacdb	17	13	24	31	25
5.	5	bedca	21	26	26	31	7

We reshape these data with `pkshape`:

```
. pkshape id seq day1 day2 day3 day4 day5
. list, sep(0)
```

	id	sequence	outcome	treat	carry	period
1.	3	1	7	1	0	1
2.	5	2	21	3	0	1
3.	2	3	13	5	0	1
4.	1	4	18	2	0	1
5.	4	5	17	4	0	1
6.	3	1	29	2	1	2
7.	5	2	26	4	3	2
8.	2	3	34	3	5	2
9.	1	4	17	5	2	2
10.	4	5	13	1	4	2
11.	3	1	32	3	2	3
12.	5	2	26	2	4	3
13.	2	3	21	4	3	3
14.	1	4	14	1	5	3
15.	4	5	24	5	1	3
16.	3	1	27	4	3	4
17.	5	2	31	5	2	4
18.	2	3	16	1	4	4
19.	1	4	21	3	1	4
20.	4	5	31	2	5	4
21.	3	1	13	5	4	5
22.	5	2	7	1	5	5
23.	2	3	15	2	1	5
24.	1	4	17	4	3	5
25.	4	5	25	3	2	5

Here the `sequence` variable is a string variable that specifies how the treatments were applied, so the `order` option is not used. When the sequence variable is a string and the `order` is specified, the arguments from the `order` option are used. We could now produce an ANOVA table:

```
. anova outcome seq period treat
```

```
                  Number of obs =      25     R-squared     =  0.8666
                  Root MSE      = 3.96232     Adj R-squared =  0.7331

          Source | Partial SS    df       MS           F     Prob > F
-----------------+----------------------------------------------------
           Model |      1223.6    12  101.966667       6.49     0.0014
                 |
        sequence |           82     4        20.5       1.31     0.3226
          period |        477.2     4       119.3       7.60     0.0027
           treat |        664.4     4       166.1      10.58     0.0007
                 |
        Residual |        188.4    12        15.7
-----------------+----------------------------------------------------
           Total |         1412    24  58.8333333
```

Example 3

Consider the Latin-square crossover example published in Kutner et al. (2005). The example is about apple sales given different methods for displaying apples.

Pattern	Store	Week 1	Week 2	Week 3
1	1	9(B)	12(C)	15(A)
	2	4(B)	12(C)	9(A)
2	1	12(A)	14(B)	3(C)
	2	13(A)	14(B)	3(C)
3	1	7(C)	18(A)	6(B)
	2	5(C)	20(A)	4(B)

We entered the data into Stata:

```
. use http://www.stata-press.com/data/r12/applesales, clear
. list, sep(2)
```

```
     +-------------------------------------------+
     | id   seq   p1   p2   p3   square          |
     |-------------------------------------------|
  1. |  1     1    9   12   15        1          |
  2. |  2     1    4   12    9        2          |
     |-------------------------------------------|
  3. |  3     2   12   14    3        1          |
  4. |  4     2   13   14    3        2          |
     |-------------------------------------------|
  5. |  5     3    7   18    6        1          |
  6. |  6     3    5   20    4        2          |
     +-------------------------------------------+
```

Now the data can be reorganized using descriptive names for the outcome variables.

```
. pkshape id seq p1 p2 p3, order(bca abc cab) seq(pattern) period(order)
> treat(displays)
```

```
. anova outcome pattern order display id|pattern
                          Number of obs =      18     R-squared     =  0.9562
                          Root MSE      = 1.59426     Adj R-squared =  0.9069
```

Source	Partial SS	df	MS	F	Prob > F
Model	443.666667	9	49.2962963	19.40	0.0002
pattern	.333333333	2	.166666667	0.07	0.9370
order	233.333333	2	116.666667	45.90	0.0000
displays	189	2	94.5	37.18	0.0001
id|pattern	21	3	7	2.75	0.1120
Residual	20.3333333	8	2.54166667		
Total	464	17	27.2941176		

These are the same results reported by Kutner et al. (2005).

◁

▷ Example 4

We continue with example 1 from [R] **pkcollapse**; the data are

◁

We call the resulting dataset `pkdata3`. We conduct equivalence testing on the data in [R] **pkequiv**, and we fit an ANOVA model to these data in the third example of [R] **pkcross**.

Methods and formulas

`pkshape` is implemented as an ado-file.

[R] **pk** — Pharmacokinetic (biopharmaceutical) data

Title

pksumm — Summarize pharmacokinetic data

Syntax

`pksumm` *id time concentration* [*if*] [*in*] [, *options*]

options	Description
Main	
`trapezoid`	use trapezoidal rule to calculate AUC; default is cubic splines
`fit(#)`	use # points to estimate AUC; default is `fit(3)`
`notimechk`	do not check whether follow-up time for all subjects is the same
`nodots`	suppress the dots during calculation
`graph`	graph the distribution of *statistic*
`stat(`*statistic*`)`	graph the specified statistic; default is `stat(auc)`
Histogram, Density plots, Y axis, X axis, Titles, Legend, Overall	
histogram_options	any option other than `by()` documented in [R] **histogram**

statistic	Description
`auc`	area under the concentration-time curve ($AUC_{0,\infty}$); the default
`aucline`	area under the concentration-time curve from 0 to ∞ using a linear extension
`aucexp`	area under the concentration-time curve from 0 to ∞ using an exponential extension
`auclog`	area under the log-concentration-time curve extended with a linear fit
`half`	half-life of the drug
`ke`	elimination rate
`cmax`	maximum concentration
`tmax`	time at last concentration
`tomc`	time of maximum concentration

Menu

Statistics > Epidemiology and related > Other > Summarize pharmacokinetic data

Description

`pksumm` obtains summary measures based on the first four moments from the empirical distribution of each pharmacokinetic measurement and tests the null hypothesis that the distribution of that measurement is normally distributed.

`pksumm` is one of the pk commands. Please read [R] **pk** before reading this entry.

Options

Main

`trapezoid` specifies that the trapezoidal rule be used to calculate the AUC. The default is cubic splines, which give better results for most situations. When the curve is irregular, the trapezoidal rule may give better results.

`fit(#)` specifies the number of points, counting back from the last time measurement, to use in fitting the extension to estimate the $AUC_{0,\infty}$. The default is `fit(3)`, the last three points. This default should be viewed as a minimum; the appropriate number of points will depend on the data.

`notimechk` suppresses the check that the follow-up time for all subjects is the same. By default, `pksumm` expects the maximum follow-up time to be equal for all subjects.

`nodots` suppresses the progress dots during calculation. By default, a period is displayed for every call to calculate the pharmacokinetic measures.

`graph` requests a graph of the distribution of the statistic specified with `stat()`.

`stat(`*statistic*`)` specifies the statistic that `pksumm` should graph. The default is `stat(auc)`. If the `graph` option is not specified, this option is ignored.

Histogram, Density plots, Y axis, X axis, Titles, Legend, Overall

histogram_options are any of the options documented in [R] **histogram**, excluding `by()`. For `pksumm`, `fraction` is the default, not `density`.

Remarks

`pksumm` produces summary statistics for the distribution of nine common pharmacokinetic measurements. If there are more than eight subjects, `pksumm` also computes a test for normality on each measurement. The nine measurements summarized by `pksumm` are listed above and are described in *Methods and formulas* of [R] **pkexamine**.

▷ Example 1

We demonstrate the use of `pksumm` on a variation of the data described in [R] **pk**. We have drug concentration data on 15 subjects, each measured at 13 time points over a 32-hour period. A few of the records are

```
. use http://www.stata-press.com/data/r12/pksumm
. list, sep(0)
```

	id	time	conc
1.	1	0	0
2.	1	.5	3.073403
3.	1	1	5.188444
4.	1	1.5	5.898577
5.	1	2	5.096378
6.	1	3	6.094085
	(*output omitted*)		
183.	15	0	0
184.	15	.5	3.86493
185.	15	1	6.432444
186.	15	1.5	6.969195
187.	15	2	6.307024
188.	15	3	6.509584
189.	15	4	6.555091
190.	15	6	7.318319
191.	15	8	5.329813
192.	15	12	5.411624
193.	15	16	3.891397
194.	15	24	5.167516
195.	15	32	2.649686

We can use `pksumm` to view the summary statistics for all the pharmacokinetic parameters.

```
. pksumm id time conc
.............
 Summary statistics for the pharmacokinetic measures
                                                Number of observations =    15
```

Measure	Mean	Median	Variance	Skewness	Kurtosis	p-value
auc	150.74	150.96	123.07	-0.26	2.10	0.69
aucline	408.30	214.17	188856.87	2.57	8.93	0.00
aucexp	691.68	297.08	762679.94	2.56	8.87	0.00
auclog	688.98	297.67	797237.24	2.59	9.02	0.00
half	94.84	29.39	18722.13	2.26	7.37	0.00
ke	0.02	0.02	0.00	0.89	3.70	0.09
cmax	7.36	7.42	0.42	-0.60	2.56	0.44
tomc	3.47	3.00	7.62	2.17	7.18	0.00
tmax	32.00	32.00	0.00	.	.	.

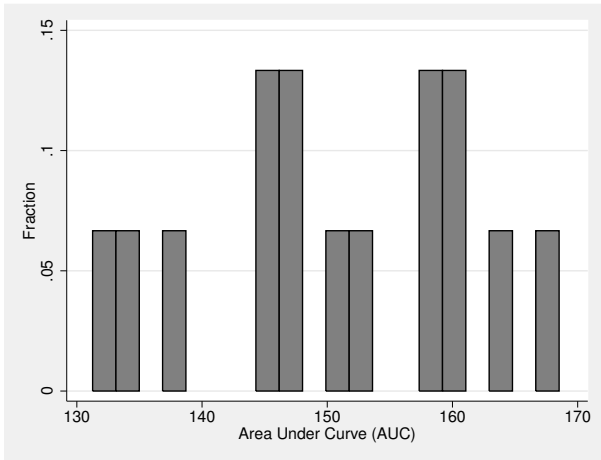
For the 15 subjects, the mean $\text{AUC}_{0,t_{\max}}$ is 150.74, and $\sigma^2 = 123.07$. The skewness of -0.26 indicates that the distribution is slightly skewed left. The p-value of 0.69 for the χ^2 test of normality indicates that we cannot reject the null hypothesis that the distribution is normal.

If we were to consider any of the three variants of the $\text{AUC}_{0,\infty}$, we would see that there is huge variability and that the distribution is heavily skewed. A skewness different from 0 and a kurtosis different from 3 are expected because the distribution of the $\text{AUC}_{0,\infty}$ is not normal.

We now graph the distribution of $\text{AUC}_{0,t_{\max}}$ by specifying the `graph` option.

```
. pksumm id time conc, graph bin(20)
.............
 Summary statistics for the pharmacokinetic measures
                                                  Number of observations =    15
```

Measure	Mean	Median	Variance	Skewness	Kurtosis	p-value
auc	150.74	150.96	123.07	-0.26	2.10	0.69
aucline	408.30	214.17	188856.87	2.57	8.93	0.00
aucexp	691.68	297.08	762679.94	2.56	8.87	0.00
auclog	688.98	297.67	797237.24	2.59	9.02	0.00
half	94.84	29.39	18722.13	2.26	7.37	0.00
ke	0.02	0.02	0.00	0.89	3.70	0.09
cmax	7.36	7.42	0.42	-0.60	2.56	0.44
tomc	3.47	3.00	7.62	2.17	7.18	0.00
tmax	32.00	32.00	0.00	.	.	.



`graph`, by default, plots $\text{AUC}_{0,t_{\max}}$. To plot a graph of one of the other pharmacokinetic measurements, we need to specify the `stat()` option. For example, we can ask Stata to produce a plot of the $\text{AUC}_{0,\infty}$ using the log extension:

```
. pksumm id time conc, stat(auclog) graph bin(20)
.............
 Summary statistics for the pharmacokinetic measures
                                                  Number of observations =    15
```

Measure	Mean	Median	Variance	Skewness	Kurtosis	p-value
auc	150.74	150.96	123.07	-0.26	2.10	0.69
aucline	408.30	214.17	188856.87	2.57	8.93	0.00

Methods and formulas

`pksumm` is implemented as an ado-file.

The χ^2 test for normality is conducted with `sktest`; see [R] **sktest** for more information on the test of normality.

The statistics reported by `pksumm` are identical to those reported by `summarize` and `sktest`; see [R] **summarize** and [R] **sktest**.

Title

poisson — Poisson regression

Syntax

```
poisson depvar [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
exposure(*varname*$_e$)	include ln(*varname*$_e$) in model with coefficient constrained to 1
offset(*varname*$_o$)	include *varname*$_o$ in model with coefficient constrained to 1
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, opg, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
irr	report incidence-rate ratios
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar, *indepvars*, *varname*$_e$, and *varname*$_o$ may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, fracpoly, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] **11.1.10 Prefix commands**.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] **mi estimate**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce() and weights are not allowed with the svy prefix; see [SVY] **svy**.

fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

coeflegend does not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Count outcomes > Poisson regression

Description

poisson fits a Poisson regression of *depvar* on *indepvars*, where *depvar* is a nonnegative count variable.

If you have panel data, see [XT] **xtpoisson**.

Options

Model

noconstant, exposure(*varname*$_e$), offset(*varname*$_o$), constraints(*constraints*), collinear; see [R] **estimation options**.

SE/Robust

vce(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

level(#); see [R] **estimation options**.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default *vcetype* to vce(opg).

The following option is available with poisson but is not shown in the dialog box:

coeflegend; see [R] **estimation options**.

Remarks

The basic idea of Poisson regression was outlined by Coleman (1964, 378–379). See Cameron and Trivedi (1998; 2010, chap. 17) and Johnson, Kemp, and Kotz (2005, chap. 4) for information about the Poisson distribution. See Cameron and Trivedi (1998), Long (1997, chap. 8), Long and Freese (2006, chap. 8), McNeil (1996, chap. 6), and Selvin (2004, chap. 9) for an introduction to Poisson regression. Also see Selvin (2004, chap. 5) for a discussion of the analysis of spatial distributions, which includes a discussion of the Poisson distribution. An early example of Poisson regression was Cochran (1940).

Poisson regression fits models of the number of occurrences (counts) of an event. The Poisson distribution has been applied to diverse events, such as the number of soldiers kicked to death by horses in the Prussian army (von Bortkiewicz 1898); the pattern of hits by buzz bombs launched against London during World War II (Clarke 1946); telephone connections to a wrong number (Thorndike 1926); and disease incidence, typically with respect to time, but occasionally with respect to space. The basic assumptions are as follows:

1. There is a quantity called the *incidence rate* that is the rate at which events occur. Examples are 5 per second, 20 per 1,000 person-years, 17 per square meter, and 38 per cubic centimeter.
2. The incidence rate can be multiplied by *exposure* to obtain the expected number of observed events. For example, a rate of 5 per second multiplied by 30 seconds means that 150 events are expected; a rate of 20 per 1,000 person-years multiplied by 2,000 person-years means that 40 events are expected; and so on.
3. Over very small exposures ϵ, the probability of finding more than one event is small compared with ϵ.
4. Nonoverlapping exposures are mutually independent.

With these assumptions, to find the probability of k events in an exposure of size E, you divide E into n subintervals E_1, E_2, ..., E_n, and approximate the answer as the binomial probability of observing k successes in n trials. If you let $n \to \infty$, you obtain the Poisson distribution.

In the Poisson regression model, the incidence rate for the jth observation is assumed to be given by

$$r_j = e^{\beta_0+\beta_1 x_{1,j}+\cdots+\beta_k x_{k,j}}$$

If E_j is the exposure, the expected number of events, C_j, will be

$$\begin{aligned} C_j &= E_j e^{\beta_0+\beta_1 x_{1,j}+\cdots+\beta_k x_{k,j}} \\ &= e^{\ln(E_j)+\beta_0+\beta_1 x_{1,j}+\cdots+\beta_k x_{k,j}} \end{aligned}$$

This model is fit by `poisson`. Without the `exposure()` or `offset()` options, E_j is assumed to be 1 (equivalent to assuming that exposure is unknown), and controlling for exposure, if necessary, is your responsibility.

Comparing rates is most easily done by calculating *incidence-rate ratios* (IRRs). For instance, what is the relative incidence rate of chromosome interchanges in cells as the intensity of radiation increases; the relative incidence rate of telephone connections to a wrong number as load increases; or the relative incidence rate of deaths due to cancer for females relative to males? That is, you want to hold all the x's in the model constant except one, say, the ith. The IRR for a one-unit change in x_i is

$$\frac{e^{\ln(E)+\beta_1 x_1+\cdots+\beta_i(x_i+1)+\cdots+\beta_k x_k}}{e^{\ln(E)+\beta_1 x_1+\cdots+\beta_i x_i+\cdots+\beta_k x_k}} = e^{\beta_i}$$

More generally, the IRR for a Δx_i change in x_i is $e^{\beta_i \Delta x_i}$. The `lincom` command can be used after `poisson` to display incidence-rate ratios for any group relative to another; see [R] **lincom**.

▷ Example 1

Chatterjee and Hadi (2006, 162) give the number of injury incidents and the proportion of flights for each airline out of the total number of flights from New York for nine major U.S. airlines in one year:

```
. use http://www.stata-press.com/data/r12/airline
. list
```

	airline	injuries	n	XYZowned
1.	1	11	0.0950	1
2.	2	7	0.1920	0
3.	3	7	0.0750	0
4.	4	19	0.2078	0
5.	5	9	0.1382	0
6.	6	4	0.0540	1
7.	7	3	0.1292	0
8.	8	1	0.0503	0
9.	9	3	0.0629	1

To their data, we have added a fictional variable, `XYZowned`. We will imagine that an accusation is made that the airlines owned by XYZ Company have a higher injury rate.

```
. poisson injuries XYZowned, exposure(n) irr
Iteration 0:   log likelihood = -23.027197
Iteration 1:   log likelihood = -23.027177
Iteration 2:   log likelihood = -23.027177
Poisson regression                                Number of obs   =          9
                                                  LR chi2(1)      =       1.77
                                                  Prob > chi2     =     0.1836
Log likelihood = -23.027177                       Pseudo R2       =     0.0370
```

injuries	IRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
XYZowned	1.463467	.406872	1.37	0.171	.8486578	2.523675
_cons	58.04416	8.558145	27.54	0.000	43.47662	77.49281
ln(n)	1	(exposure)				

We specified `irr` to see the IRRs rather than the underlying coefficients. We estimate that XYZ Airlines' injury rate is 1.46 times larger than that for other airlines, but the 95% confidence interval is 0.85 to 2.52; we cannot even reject the hypothesis that XYZ Airlines has a lower injury rate.

◁

❑ Technical note

In example 1, we assumed that each airline's exposure was proportional to its fraction of flights out of New York. What if "large" airlines, however, also used larger planes, and so had even more passengers than would be expected, given this measure of exposure? A better measure would be each airline's fraction of passengers on flights out of New York, a number that we do not have. Even so, we suppose that `n` represents this number to some extent, so a better estimate of the effect might be

```
. gen lnN=ln(n)
. poisson injuries XYZowned lnN
Iteration 0:   log likelihood = -22.333875
Iteration 1:   log likelihood = -22.332276
Iteration 2:   log likelihood = -22.332276
Poisson regression                              Number of obs   =          9
                                                LR chi2(2)      =      19.15
                                                Prob > chi2     =     0.0001
Log likelihood = -22.332276                     Pseudo R2       =     0.3001

------------------------------------------------------------------------------
    injuries |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
    XYZowned |   .6840667   .3895877     1.76   0.079    -.0795111    1.447645
         lnN |   1.424169   .3725155     3.82   0.000     .6940517    2.154285
       _cons |   4.863891   .7090501     6.86   0.000     3.474178    6.253603
------------------------------------------------------------------------------
```

Here rather than specifying the `exposure()` option, we explicitly included the variable that would normalize for exposure in the model. We did not specify the `irr` option, so we see coefficients rather than IRRs. We started with the model

$$\text{rate} = e^{\beta_0+\beta_1 \text{XYZowned}}$$

The observed counts are therefore

$$\text{count} = ne^{\beta_0+\beta_1 \text{XYZowned}} = e^{\ln(n)+\beta_0+\beta_1 \text{XYZowned}}$$

which amounts to constraining the coefficient on $\ln(\texttt{n})$ to 1. This is what was estimated when we specified the `exposure(n)` option. In the above model, we included the normalizing exposure ourselves and, rather than constraining the coefficient to be 1, estimated the coefficient.

The estimated coefficient is 1.42, a respectable distance away from 1, and is consistent with our speculation that larger airlines also use larger airplanes. With this small amount of data, however, we also have a wide confidence interval that includes 1.

Our estimated *coefficient* on `XYZowned` is now 0.684, and the implied IRR is $e^{0.684} \approx 1.98$ (which we could also see by typing `poisson, irr`). The 95% confidence interval for the coefficient still includes 0 (the interval for the IRR includes 1), so although the point estimate is now larger, we still cannot be certain of our results.

Our expert opinion would be that, although there is not enough evidence to support the charge, there is enough evidence to justify collecting more data.

❑

▷ Example 2

In a famous age-specific study of coronary disease deaths among male British doctors, Doll and Hill (1966) reported the following data (reprinted in Rothman, Greenland, and Lash [2008, 264]):

	Smokers		Nonsmokers	
Age	Deaths	Person-years	Deaths	Person-years
35–44	32	52,407	2	18,790
45–54	104	43,248	12	10,673
55–64	206	28,612	28	5,710
65–74	186	12,663	28	2,585
75–84	102	5,317	31	1,462

The first step is to enter these data into Stata, which we have done:

```
. use http://www.stata-press.com/data/r12/dollhill3, clear
. list
```

	agecat	smokes	deaths	pyears
1.	1	1	32	52,407
2.	2	1	104	43,248
3.	3	1	206	28,612
4.	4	1	186	12,663
5.	5	1	102	5,317
6.	1	0	2	18,790
7.	2	0	12	10,673
8.	3	0	28	5,710
9.	4	0	28	2,585
10.	5	0	31	1,462

`agecat` 1 corresponds to 35–44, `agecat` 2 to 45–54, and so on. The most "natural" analysis of these data would begin by introducing indicator variables for each age category and one indicator for smoking:

```
. poisson deaths smokes i.agecat, exposure(pyears) irr
Iteration 0:   log likelihood = -33.823284
Iteration 1:   log likelihood = -33.600471
Iteration 2:   log likelihood = -33.600153
Iteration 3:   log likelihood = -33.600153
Poisson regression                              Number of obs   =         10
                                                LR chi2(5)      =     922.93
                                                Prob > chi2     =     0.0000
Log likelihood = -33.600153                     Pseudo R2       =     0.9321
```

deaths	IRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
smokes	1.425519	.1530638	3.30	0.001	1.154984	1.759421
agecat						
2	4.410584	.8605197	7.61	0.000	3.009011	6.464997
3	13.8392	2.542638	14.30	0.000	9.654328	19.83809
4	28.51678	5.269878	18.13	0.000	19.85177	40.96395
5	40.45121	7.775511	19.25	0.000	27.75326	58.95885
_cons	.0003636	.0000697	-41.30	0.000	.0002497	.0005296
ln(pyears)	1	(exposure)				

In the above, we specified `irr` to obtain IRRs. We estimate that smokers have 1.43 times the mortality rate of nonsmokers. See, however, example 1 in [R] **poisson postestimation**.

Saved results

poisson saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(k_eq_model)	number of equations in overall model test
e(k_dv)	number of dependent variables
e(df_m)	model degrees of freedom
e(r2_p)	pseudo-R-squared
e(ll)	log likelihood
e(ll_0)	log likelihood, constant-only model
e(N_clust)	number of clusters
e(chi2)	χ^2
e(p)	significance
e(rank)	rank of e(V)
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	poisson
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method

e(technique)	maximization technique
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Siméon-Denis Poisson (1781–1840) was a French mathematician and physicist who contributed to several fields: his name is perpetuated in Poisson brackets, Poisson's constant, Poisson's differential equation, Poisson's integral, and Poisson's ratio. Among many other results, he produced a version of the law of large numbers. His rather misleadingly titled *Recherches sur la probabilité des jugements* embraces a complete treatise on probability, as the subtitle indicates, including what is now known as the Poisson distribution. That, however, was discovered earlier by the Huguenot–British mathematician Abraham de Moivre (1667–1754).

Methods and formulas

`poisson` is implemented as an ado-file.

The log likelihood (with weights w_j and offsets) is given by

$$\Pr(Y=y) = \frac{e^{-\lambda}\lambda^{y}}{y!}$$

$$\xi_j = \mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$$

$$f(y_j) = \frac{e^{-\exp(\xi_j)}e^{\xi_j y_j}}{y_j!}$$

$$\ln L = \sum_{j=1}^{n} w_j \left\{-e^{\xi_j} + \xi_j y_j - \ln(y_j!)\right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`poisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Title

poisson postestimation — Postestimation tools for poisson

Description

The following postestimation command is of special interest after `poisson`:

Command	Description
`estat gof`	goodness-of-fit test

`estat gof` is not appropriate after the `svy` prefix. For information about `estat gof`, see below.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Special-interest postestimation command

`estat gof` performs a goodness-of-fit test of the model. Both the deviance statistic and the Pearson statistic are reported. If the tests are significant, the Poisson regression model is inappropriate. Then you could try a negative binomial model; see [R] **nbreg**.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

statistic	Description
Main	
`n`	number of events; the default
`ir`	incidence rate
`pr(`*n*`)`	probability $\Pr(y_j = n)$
`pr(`*a*`,`*b*`)`	probability $\Pr(a \leq y_j \leq b)$
`xb`	linear prediction
`stdp`	standard error of the linear prediction
`score`	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`n`, the default, calculates the predicted number of events, which is $\exp(\mathbf{x}_j\boldsymbol{\beta})$ if neither `offset()` nor `exposure()` was specified when the model was fit; $\exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ if `offset()` was specified; or $\exp(\mathbf{x}_j\boldsymbol{\beta}) \times \text{exposure}_j$ if `exposure()` was specified.

`ir` calculates the incidence rate $\exp(\mathbf{x}_j\boldsymbol{\beta})$, which is the predicted number of events when exposure is 1. Specifying `ir` is equivalent to specifying `n` when neither `offset()` nor `exposure()` was specified when the model was fit.

`pr(`*n*`)` calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable.

`pr(`*a*`,`*b*`)` calculates the probability $\Pr(a \leq y_j \leq b)$, where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

b missing ($b \geq .$) means $+\infty$;
`pr(20,.)` calculates $\Pr(y_j \geq 20)$;
`pr(20,`*b*`)` calculates $\Pr(y_j \geq 20)$ in observations for which $b \geq .$ and calculates $\Pr(20 \leq y_j \leq b)$ elsewhere.

`pr(.,`*b*`)` produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for `pr(`*a*`,`*b*`)`.

`xb` calculates the linear prediction, which is $\mathbf{x}_j\boldsymbol{\beta}$ if neither `offset()` nor `exposure()` was specified; $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$ if `offset()` was specified; or $\mathbf{x}_j\boldsymbol{\beta} + \ln(\text{exposure}_j)$ if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\boldsymbol{\beta}$ rather than as $\mathbf{x}_j\boldsymbol{\beta}+\text{offset}_j$ or $\mathbf{x}_j\boldsymbol{\beta}+\ln(\text{exposure}_j)$. Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

Syntax for estat gof

```
estat gof
```

Statistics > Postestimation > Reports and statistics

Remarks

▷ Example 1

Continuing with example 2 of [R] **poisson**, we use `estat gof` to determine whether the model fits the data well.

```
. use http://www.stata-press.com/data/r12/dollhill3
. poisson deaths smokes i.agecat, exp(pyears) irr
  (output omitted)
. estat gof
        Deviance goodness-of-fit =  12.13244
        Prob > chi2(4)           =    0.0164
        Pearson goodness-of-fit  =  11.15533
        Prob > chi2(4)           =    0.0249
```

The deviance goodness-of-fit test tells us that, given the model, we can reject the hypothesis that these data are Poisson distributed at the 1.64% significance level. The Pearson goodness-of-fit test tells us that we can reject the hypothesis at the 2.49% significance level.

So let us now back up and be more careful. We can most easily obtain the incidence-rate ratios within age categories by using `ir`; see [ST] **epitab**:

```
. ir deaths smokes pyears, by(agecat) nohet
```

agecat	IRR	[95% Conf.	Interval]	M-H Weight	
1	5.736638	1.463557	49.40468	1.472169	(exact)
2	2.138812	1.173714	4.272545	9.624747	(exact)
3	1.46824	.9863624	2.264107	23.34176	(exact)
4	1.35606	.9081925	2.096412	23.25315	(exact)
5	.9047304	.6000757	1.399687	24.31435	(exact)
Crude	1.719823	1.391992	2.14353		(exact)
M-H combined	1.424682	1.154703	1.757784		

We find that the mortality incidence ratios are greatly different within age category, being highest for the youngest categories and actually dropping below 1 for the oldest. (In the last case, we might argue that those who smoke and who have not died by age 75 are self-selected to be particularly robust.)

Seeing this, we will now parameterize the smoking effects separately for each age category, although we will begin by constraining the smoking effects on age categories 3 and 4 to be equivalent:

```
. constraint 1 smokes#3.agecat = smokes#4.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1)
Iteration 0:   log likelihood =  -31.95424
Iteration 1:   log likelihood = -27.796801
Iteration 2:   log likelihood = -27.574177
Iteration 3:   log likelihood = -27.572645
Iteration 4:   log likelihood = -27.572645
Poisson regression                                Number of obs   =         10
                                                  Wald chi2(8)    =     632.14
Log likelihood = -27.572645                       Prob > chi2     =     0.0000
 ( 1)  [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
```

deaths	IRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
agecat#c.smokes						
1	5.736637	4.181256	2.40	0.017	1.374811	23.93711
2	2.138812	.6520701	2.49	0.013	1.176691	3.887609
3	1.412229	.2017485	2.42	0.016	1.067343	1.868557
4	1.412229	.2017485	2.42	0.016	1.067343	1.868557
5	.9047304	.1855513	-0.49	0.625	.6052658	1.35236
agecat						
2	10.5631	8.067701	3.09	0.002	2.364153	47.19623
3	47.671	34.37409	5.36	0.000	11.60056	195.8978
4	98.22765	70.85012	6.36	0.000	23.89324	403.8244
5	199.2099	145.3356	7.26	0.000	47.67693	832.3648
_cons	.0001064	.0000753	-12.94	0.000	.0000266	.0004256
ln(pyears)	1	(exposure)				

```
. estat gof
        Deviance goodness-of-fit =  .0774185
        Prob > chi2(1)           =    0.7808
        Pearson goodness-of-fit  =  .0773882
        Prob > chi2(1)           =    0.7809
```

The goodness-of-fit is now small; we are no longer running roughshod over the data. Let us now consider simplifying the model. The point estimate of the incidence-rate ratio for smoking in age category 1 is much larger than that for smoking in age category 2, but the confidence interval for `smokes#1.agecat` is similarly wide. Is the difference real?

```
. test smokes#1.agecat = smokes#2.agecat
 ( 1)  [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
           chi2(  1) =    1.56
         Prob > chi2 =    0.2117
```

The point estimates may be far apart, but there is insufficient data, and we may be observing random differences. With that success, might we also combine the smokers in age categories 3 and 4 with those in 1 and 2?

```
. test smokes#2.agecat = smokes#3.agecat, accum
 ( 1)  [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
 ( 2)  [deaths]2.agecat#c.smokes - [deaths]3.agecat#c.smokes = 0
           chi2(  2) =    4.73
         Prob > chi2 =    0.0938
```

Combining age categories 1–4 may be overdoing it—the 9.38% significance level is enough to stop us, although others may disagree.

Thus we now fit our final model:

```
. constraint 2 smokes#1.agecat = smokes#2.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1/2)
Iteration 0:   log likelihood = -31.550722
Iteration 1:   log likelihood = -28.525057
Iteration 2:   log likelihood = -28.514535
Iteration 3:   log likelihood = -28.514535
Poisson regression                              Number of obs   =         10
                                                Wald chi2(7)    =     642.25
Log likelihood = -28.514535                     Prob > chi2     =     0.0000
 ( 1)  [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
 ( 2)  [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
```

deaths	IRR	Std. Err.	z	P>|z|	[95% Conf.	Interval]
agecat#c.smokes						
1	2.636259	.7408403	3.45	0.001	1.519791	4.572907
2	2.636259	.7408403	3.45	0.001	1.519791	4.572907
3	1.412229	.2017485	2.42	0.016	1.067343	1.868557
4	1.412229	.2017485	2.42	0.016	1.067343	1.868557
5	.9047304	.1855513	-0.49	0.625	.6052658	1.35236
agecat						
2	4.294559	.8385329	7.46	0.000	2.928987	6.296797
3	23.42263	7.787716	9.49	0.000	12.20738	44.94164
4	48.26309	16.06939	11.64	0.000	25.13068	92.68856
5	97.87965	34.30881	13.08	0.000	49.24123	194.561
_cons	.0002166	.0000652	-28.03	0.000	.0001201	.0003908
ln(pyears)	1	(exposure)				

The above strikes us as a fair representation of the data. The probabilities of observing the deaths seen in these data are estimated using the following `predict` command:

```
. predict p, pr(0, deaths)
. list deaths p
```

	deaths	p
1.	32	.6891766
2.	104	.4456625
3.	206	.5455328
4.	186	.4910622
5.	102	.5263011
6.	2	.227953
7.	12	.7981917
8.	28	.4772961
9.	28	.6227565
10.	31	.5475718

The probability $\Pr(y \leq \texttt{deaths})$ ranges from 0.23 to 0.80.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

In the following, we use the same notation as in [R] **poisson**.

The equation-level scores are given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = y_j - e^{\xi_j}$$

The deviance (D) and Pearson (P) goodness-of-fit statistics are given by

$$\ln L_{\max} = \sum_{j=1}^{n} w_j \left[-y_j\{\ln(y_j) - 1\} - \ln(y_j!)\right]$$

$$\chi^2_D = -2\{\ln L - \ln L_{\max}\}$$

$$\chi^2_P = \sum_{j=1}^{n} \frac{w_j(y_j - e^{\xi_j})^2}{e^{\xi_j}}$$

[U] **20 Estimation and postestimation commands**

Title

predict — Obtain predictions, residuals, etc., after estimation

Syntax

After single-equation (SE) *models*

```
predict [type] newvar [if] [in] [, single_options]
```

After multiple-equation (ME) *models*

```
predict [type] newvar [if] [in] [, multiple_options]
predict [type] { stub* | newvar1 ... newvarq } [if] [in], scores
```

single_options	Description
Main	
`xb`	calculate linear prediction
`stdp`	calculate standard error of the prediction
`score`	calculate first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$
Options	
`nooffset`	ignore any `offset()` or `exposure()` variable
other_options	command-specific options

multiple_options	Description
Main	
`equation(`*eqno*`[ , `*eqno*`])`	specify equations
`xb`	calculate linear prediction
`stdp`	calculate standard error of the prediction
`stddp`	calculate the difference in linear predictions
Options	
`nooffset`	ignore any `offset()` or `exposure()` variable
other_options	command-specific options

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Description

`predict` calculates predictions, residuals, influence statistics, and the like after estimation. Exactly what `predict` can do is determined by the previous estimation command; command-specific options are documented with each estimation command. Regardless of command-specific options, the actions of `predict` share certain similarities across estimation commands:

1. `predict` *newvar* creates *newvar* containing "predicted values"—numbers related to the $E(y_j|\mathbf{x}_j)$. For instance, after linear regression, `predict` *newvar* creates $\mathbf{x}_j\mathbf{b}$ and, after probit, creates the probability $\Phi(\mathbf{x}_j\mathbf{b})$.
2. `predict` *newvar*`, xb` creates *newvar* containing $\mathbf{x}_j\mathbf{b}$. This may be the same result as option 1 (for example, linear regression) or different (for example, probit), but regardless, option `xb` is allowed.
3. `predict` *newvar*`, stdp` creates *newvar* containing the standard error of the linear prediction $\mathbf{x}_j\mathbf{b}$.
4. `predict` *newvar*`,` *other_options* may create *newvar* containing other useful quantities; see `help` or the reference manual entry for the particular estimation command to find out about other available options.
5. `nooffset` added to any of the above commands requests that the calculation ignore any offset or exposure variable specified by including the `offset(`*varname*$_o$`)` or `exposure(`*varname*$_e$`)` option when you fit the model.

`predict` can be used to make in-sample or out-of-sample predictions:

6. `predict` calculates the requested statistic for all possible observations, whether they were used in fitting the model or not. `predict` does this for standard options 1–3 and generally does this for estimator-specific options 4.
7. `predict` *newvar* `if e(sample), ...` restricts the prediction to the estimation subsample.
8. Some statistics make sense only with respect to the estimation subsample. In such cases, the calculation is automatically restricted to the estimation subsample, and the documentation for the specific option states this. Even so, you can still specify `if e(sample)` if you are uncertain.
9. `predict` can make out-of-sample predictions even using other datasets. In particular, you can

```
. use ds1
. (fit a model)
. use two                       /* another dataset         */
. predict yhat, ...             /* fill in the predictions */
```

Options

Main

`xb` calculates the linear prediction from the fitted model. That is, all models can be thought of as estimating a set of parameters b_1, b_2, ..., b_k, and the linear prediction is $\widehat{y}_j = b_1x_{1j} + b_2x_{2j} + \cdots + b_kx_{kj}$, often written in matrix notation as $\widehat{\mathbf{y}}_j = \mathbf{x}_j\mathbf{b}$. For linear regression, the values $\widehat{y}_j$ are called the predicted values or, for out-of-sample predictions, the forecast. For logit and probit, for example, $\widehat{y}_j$ is called the logit or probit index.

$x_{1j}, x_{2j}, \ldots, x_{kj}$ are obtained from the data currently in memory and do not necessarily correspond to the data on the independent variables used to fit the model (obtaining b_1, b_2, ..., b_k).

`stdp` calculates the standard error of the linear prediction. Here the prediction means the same thing as the "index", namely, $\mathbf{x}_j\mathbf{b}$. The statistic produced by `stdp` can be thought of as the standard error of the predicted expected value, or mean index, for the observation's covariate pattern. The standard error of the prediction is also commonly referred to as the standard error of the fitted value. The calculation can be made in or out of sample.

`stddp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ($\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$) between equations 1 and 2 is calculated. This option requires that `equation(`*eqno*$_1$`,`*eqno*$_2$`)` be specified.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$. Here $\ln L$ refers to the log-likelihood function.

`scores` is the ME model equivalent of the `score` option, resulting in multiple equation-level score variables. An equation-level score variable is created for each equation in the model; ancillary parameters—such as $\ln\sigma$ and $\operatorname{atanh}\rho$—make up separate equations.

`equation(`*eqno*`[ ,`*eqno*`])`—synonym `outcome()`—is relevant only when you have previously fit a multiple-equation model. It specifies the equation to which you are referring.

`equation()` is typically filled in with one *eqno*—it would be filled in that way with options `xb` and `stdp`, for instance. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

Other statistics, such as `stddp`, refer to between-equation concepts. In those cases, you might specify `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

Options

`nooffset` may be combined with most statistics and specifies that the calculation should be made, ignoring any offset or exposure variable specified when the model was fit.

This option is available, even if it is not documented for `predict` after a specific command. If neither the `offset(`*varname*$_o$`)` option nor the `exposure(`*varname*$_e$`)` option was specified when the model was fit, specifying `nooffset` does nothing.

other_options refers to command-specific options that are documented with each command.

Remarks

Remarks are presented under the following headings:

Estimation-sample predictions
Out-of-sample predictions
Residuals
Single-equation (SE) models
SE model scores
Multiple-equation (ME) models
ME model scores

Most of the examples are presented using linear regression, but the general syntax is applicable to all estimators.

You can think of any estimation command as estimating a set of coefficients b_1, b_2, …, b_k corresponding to the variables x_1, x_2, …, x_k, along with a (possibly empty) set of ancillary statistics γ_1, γ_2, …, γ_m. All estimation commands save the b_is and γ_is. `predict` accesses that saved information and combines it with the data currently in memory to make various calculations. For instance, `predict` can calculate the linear prediction, $\widehat{y}_j = b_1x_{1j} + b_2x_{2j} + \cdots + b_kx_{kj}$. The data on which `predict` makes the calculation can be the same data used to fit the model or a different dataset—it does not matter. `predict` uses the saved parameter estimates from the model, obtains

the corresponding values of x for each observation in the data, and then combines them to produce the desired result.

Estimation-sample predictions

▷ Example 1

We have a 74-observation dataset on automobiles, including the mileage rating (`mpg`), the car's weight (`weight`), and whether the car is foreign (`foreign`). We fit the model

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight if foreign
```

Source	SS	df	MS	Number of obs =	22
				F(1, 20) =	17.47
Model	427.990298	1	427.990298	Prob > F =	0.0005
Residual	489.873338	20	24.4936669	R-squared =	0.4663
				Adj R-squared =	0.4396
Total	917.863636	21	43.7077922	Root MSE =	4.9491

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.010426	.0024942	-4.18	0.000	-.0156287	-.0052232
_cons	48.9183	5.871851	8.33	0.000	36.66983	61.16676

If we were to type `predict pmpg` now, we would obtain the linear predictions for all 74 observations. To obtain the predictions just for the sample on which we fit the model, we could type

```
. predict pmpg if e(sample)
(option xb assumed; fitted values)
(52 missing values generated)
```

Here `e(sample)` is true only for foreign cars because we typed `if foreign` when we fit the model and because there are no missing values among the relevant variables. If there had been missing values, `e(sample)` would also account for those.

By the way, the `if e(sample)` restriction can be used with any Stata command, so we could obtain summary statistics on the estimation sample by typing

```
. summarize if e(sample)
```
(*output omitted*)

◁

Out-of-sample predictions

By out-of-sample predictions, we mean predictions extending beyond the estimation sample. In the example above, typing `predict pmpg` would generate linear predictions using all 74 observations.

`predict` will work on other datasets, too. You can use a new dataset and type `predict` to obtain results for that sample.

▷ Example 2

Using the same auto dataset, assume that we wish to fit the model

$$\texttt{mpg} = \beta_1\texttt{weight} + \beta_2\ln(\texttt{weight}) + \beta_3\texttt{foreign} + \beta_4$$

We first create the ln(weight) variable, and then type the `regress` command:

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
```

Source	SS	df	MS	Number of obs =	74
				F(3, 70) =	52.36
Model	1690.27997	3	563.426657	Prob > F =	0.0000
Residual	753.179489	70	10.759707	R-squared =	0.6918
				Adj R-squared =	0.6785
Total	2443.45946	73	33.4720474	Root MSE =	3.2802

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	.003304	.0038995	0.85	0.400	-.0044734	.0110813
lnweight	-29.59133	11.52018	-2.57	0.012	-52.5676	-6.615061
foreign	-2.125299	1.052324	-2.02	0.047	-4.224093	-.0265044
_cons	248.0548	80.37079	3.09	0.003	87.76035	408.3493

If we typed `predict pmpg` now, we would obtain predictions for all 74 cars in the current data. Instead, we are going to use a new dataset.

The dataset `newautos.dta` contains the make, weight, and place of manufacture of two cars, the Pontiac Sunbird and the Volvo 260. Let's use the dataset and create the predictions:

```
. use http://www.stata-press.com/data/r12/newautos, clear
(New Automobile Models)
. list
```

	make	weight	foreign
1.	Pont. Sunbird	2690	Domestic
2.	Volvo 260	3170	Foreign

```
. predict mpg
(option xb assumed; fitted values)
variable lnweight not found
r(111);
```

Things did not work. We typed `predict mpg`, and Stata responded with the message "variable lnweight not found". `predict` can calculate predicted values on a different dataset only if that dataset contains the variables that went into the model. Here our dataset does not contain a variable called `lnweight`. `lnweight` is just the log of weight, so we can create it and try again:

```
. generate lnweight = ln(weight)
. predict mpg
(option xb assumed; fitted values)
```

```
. list
```

	make	weight	foreign	lnweight	mpg
1.	Pont. Sunbird	2690	Domestic	7.897296	23.25097
2.	Volvo 260	3170	Foreign	8.061487	17.85295

We obtained our predicted values. The Pontiac Sunbird has a predicted mileage rating of 23.3 mpg, whereas the Volvo 260 has a predicted rating of 17.9 mpg.

◁

Residuals

▷ Example 3

With many estimators, `predict` can calculate more than predicted values. With most regression-type estimators, we can, for instance, obtain residuals. Using our regression example, we return to our original data and obtain residuals by typing

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
  (output omitted)
. predict double resid, residuals
. summarize resid
```

Variable	Obs	Mean	Std. Dev.	Min	Max
resid	74	-1.51e-15	3.212091	-5.453078	13.83719

We could do this without refitting the model. Stata always remembers the last set of estimates, even as we use new datasets.

It was not necessary to type the `double` in `predict double resid, residuals`, but we wanted to remind you that you can specify the type of a variable in front of the variable's name; see [U] **11.4.2 Lists of new variables**. We made the new variable `resid` a `double` rather than the default `float`.

If you want your residuals to have a mean as close to zero as possible, remember to request the extra precision of `double`. If we had not specified `double`, the mean of `resid` would have been roughly 10^{-9} rather than 10^{-14}. Although 10^{-14} sounds more precise than 10^{-9}, the difference really does not matter.

◁

For linear regression, `predict` can also calculate standardized residuals and Studentized residuals with the options `rstandard` and `rstudent`; for examples, see [R] **regress postestimation**.

Single-equation (SE) models

If you have not read the discussion above on using `predict` after linear regression, please do so. And `predict`'s default calculation almost always produces a statistic in the same metric as the dependent variable of the fitted model—for example, predicted counts for Poisson regression. In any case, `xb` can always be specified to obtain the linear prediction.

`predict` can calculate the standard error of the prediction, which is obtained by using the covariance matrix of the estimators.

▷ Example 4

After most binary outcome models (for example, `logistic`, `logit`, `probit`, `cloglog`, `scobit`), `predict` calculates the probability of a positive outcome if we do not tell it otherwise. We can specify the `xb` option if we want the linear prediction (also known as the logit or probit index). The odd abbreviation `xb` is meant to suggest $\mathbf{x}\boldsymbol{\beta}$. In logit and probit models, for example, the predicted probability is $p = F(\mathbf{x}\boldsymbol{\beta})$, where $F()$ is the logistic or normal cumulative distribution function, respectively.

```
. logistic foreign mpg weight
  (output omitted)
. predict phat
(option pr assumed; Pr(foreign))
. predict idxhat, xb
. summarize foreign phat idxhat
```

Variable	Obs	Mean	Std. Dev.	Min	Max
foreign	74	.2972973	.4601885	0	1
phat	74	.2972973	.3052979	.000729	.8980594
idxhat	74	-1.678202	2.321509	-7.223107	2.175845

Because this is a logit model, we could obtain the predicted probabilities ourselves from the predicted index

```
. generate phat2 = exp(idxhat)/(1+exp(idxhat))
```

but using `predict` without options is easier.

◁

▷ Example 5

For all models, `predict` attempts to produce a predicted value in the same metric as the dependent variable of the model. We have seen that for dichotomous outcome models, the default statistic produced by `predict` is the probability of a success. Similarly, for Poisson regression, the default statistic produced by `predict` is the predicted count for the dependent variable. You can always specify the `xb` option to obtain the linear combination of the coefficients with an observation's x values (the inner product of the coefficients and x values). For `poisson` (without an explicit exposure), this is the natural log of the count.

```
. use http://www.stata-press.com/data/r12/airline, clear
. poisson injuries XYZowned
  (output omitted)
. predict injhat
(option n assumed; predicted number of events)
```

```
. predict idx, xb
. generate exp_idx = exp(idx)
. summarize injuries injhat exp_idx idx
```

Variable	Obs	Mean	Std. Dev.	Min	Max
injuries	9	7.111111	5.487359	1	19
injhat	9	7.111111	.8333333	6	7.666667
exp_idx	9	7.111111	.8333333	6	7.666667
idx	9	1.955174	.1225612	1.791759	2.036882

We note that our "hand-computed" prediction of the count (`exp_idx`) matches what was produced by the default operation of `predict`.

If our model has an exposure-time variable, we can use `predict` to obtain the linear prediction with or without the exposure. Let's verify what we are getting by obtaining the linear prediction with and without exposure, transforming these predictions to count predictions and comparing them with the default count prediction from `predict`. We must remember to multiply by the exposure time when using `predict ..., nooffset`.

```
. use http://www.stata-press.com/data/r12/airline, clear
. poisson injuries XYZowned, exposure(n)
  (output omitted)
. predict double injhat
(option n assumed; predicted number of events)
. predict double idx, xb
. generate double exp_idx = exp(idx)
. predict double idxn, xb nooffset
. generate double exp_idxn = exp(idxn)*n
. summarize injuries injhat exp_idx exp_idxn idx idxn
```

Variable	Obs	Mean	Std. Dev.	Min	Max
injuries	9	7.111111	5.487359	1	19
injhat	9	7.111111	3.10936	2.919621	12.06158
exp_idx	9	7.111111	3.10936	2.919621	12.06158
exp_idxn	9	7.111111	3.10936	2.919621	12.06158
idx	9	1.869722	.4671044	1.071454	2.490025
idxn	9	4.18814	.1904042	4.061204	4.442013

Looking at the identical means and standard deviations for `injhat`, `exp_idx`, and `exp_idxn`, we see that we can reproduce the default computations of `predict` for `poisson` estimations. We have also demonstrated the relationship between the count predictions and the linear predictions with and without exposure.

◁

SE model scores

▷ Example 6

With most maximum likelihood estimators, `predict` can calculate equation-level scores. The first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$ is the equation-level score.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. logistic foreign mpg weight
  (output omitted)
```

```
. predict double sc, score
. summarize sc
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
          sc |         74   -1.37e-12    .3533133  -.8760856   .8821309
```

See [P] **_robust** and [SVY] **variance estimation** for details regarding the role equation-level scores play in linearization-based variance estimators. ◁

❑ Technical note

`predict` after some estimation commands, such as `regress` and `cnsreg`, allows the `score` option as a synonym for the `residuals` option. ❑

Multiple-equation (ME) models

If you have not read the above discussion on using `predict` after SE models, please do so. With the exception of the ability to select specific equations to predict from, the use of `predict` after ME models follows almost the same form that it does for SE models.

▷ Example 7

The details of prediction statistics that are specific to particular ME models are documented with the estimation command. If you are using ME commands that do not have separate discussions on obtaining predictions, read *Obtaining predicted values* in [R] **mlogit postestimation**, even if your interest is not in multinomial logistic regression. As a general introduction to the ME models, we will demonstrate `predict` after `sureg`:

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. sureg (price foreign displ) (weight foreign length)
Seemingly unrelated regression
------------------------------------------------------------------------------
Equation              Obs  Parms        RMSE    "R-sq"       chi2         P
------------------------------------------------------------------------------
price                  74      2    2202.447    0.4348      45.21    0.0000
weight                 74      2    245.5238    0.8988     658.85    0.0000
------------------------------------------------------------------------------

------------------------------------------------------------------------------
             |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
price        |
     foreign |   3137.894   697.3805     4.50   0.000     1771.054    4504.735
displacement |   23.06938   3.443212     6.70   0.000     16.32081    29.81795
       _cons |   680.8438   859.8142     0.79   0.428    -1004.361    2366.049
-------------+----------------------------------------------------------------
weight       |
     foreign |  -154.883    75.3204    -2.06   0.040    -302.5082   -7.257674
      length |   30.67594   1.531981    20.02   0.000     27.67331    33.67856
       _cons |  -2699.498   302.3912    -8.93   0.000    -3292.173   -2106.822
------------------------------------------------------------------------------
```

sureg estimated two equations, one called price and the other weight; see [R] **sureg**.

```
. predict pred_p, equation(price)
(option xb assumed; fitted values)
. predict pred_w, equation(weight)
(option xb assumed; fitted values)
. summarize price pred_p weight pred_w
```

Variable	Obs	Mean	Std. Dev.	Min	Max
price	74	6165.257	2949.496	3291	15906
pred_p	74	6165.257	1678.805	2664.81	10485.33
weight	74	3019.459	777.1936	1760	4840
pred_w	74	3019.459	726.0468	1501.602	4447.996

You may specify the equation by name, as we did above, or by number: equation(#1) means the same thing as equation(price) in this case.

◁

ME model scores

▷ Example 8

For ME models, predict allows you to specify a stub when generating equation-level score variables. predict generates new variables using this stub by appending an equation index. Depending upon the command, the index will start with 0 or 1. Here is an example where predict starts indexing the score variables with 0.

```
. ologit rep78 mpg weight
  (output omitted)
. predict double sc*, scores
. summarize sc*
```

Variable	Obs	Mean	Std. Dev.	Min	Max
sc0	69	-1.33e-11	.5337363	-.9854088	.921433
sc1	69	-7.69e-13	.186919	-.2738537	.9854088
sc2	69	-2.87e-11	.4061637	-.5188487	1.130178
sc3	69	-1.04e-10	.5315368	-1.067351	.8194842
sc4	69	1.47e-10	.360525	-.921433	.6140182

Although it involves much more typing, we could also specify the new variable names individually.

```
. predict double (sc_xb sc_1 sc_2 sc_3 sc_4), scores
. summarize sc_*
```

Variable	Obs	Mean	Std. Dev.	Min	Max
sc_xb	69	-1.33e-11	.5337363	-.9854088	.921433
sc_1	69	-7.69e-13	.186919	-.2738537	.9854088
sc_2	69	-2.87e-11	.4061637	-.5188487	1.130178
sc_3	69	-1.04e-10	.5315368	-1.067351	.8194842
sc_4	69	1.47e-10	.360525	-.921433	.6140182

◁

Methods and formulas

`predict` is implemented as an ado-file.

Denote the previously estimated coefficient vector as $\mathbf{b}$ and its estimated variance matrix as $\mathbf{V}$. `predict` works by recalling various aspects of the model, such as $\mathbf{b}$, and combining that information with the data currently in memory. Let's write $\mathbf{x}_j$ for the jth observation currently in memory.

The *predicted value* (`xb` option) is defined as $\widehat{y}_j = \mathbf{x}_j\mathbf{b} + \text{offset}_j$

The *standard error of the prediction* (the `stdp` option) is defined as $s_{p_j} = \sqrt{\mathbf{x}_j\mathbf{V}\mathbf{x}_j'}$

The *standard error of the difference in linear predictions* between equations 1 and 2 is defined as

$$s_{dp_j} = \{(\mathbf{x}_{1j}, -\mathbf{x}_{2j}, \mathbf{0}, \ldots, \mathbf{0})\,\mathbf{V}\,(\mathbf{x}_{1j}, -\mathbf{x}_{2j}, \mathbf{0}, \ldots, \mathbf{0})'\}^{\frac{1}{2}}$$

See the individual estimation commands for information about calculating command-specific `predict` statistics.

Title

predictnl — Obtain nonlinear predictions, standard errors, etc., after estimation

Syntax

`predictnl` [*type*] *newvar* = *pnl_exp* [*if*] [*in*] [, *options*]

options	Description
Main	
`se(`*newvar*`)`	create *newvar* containing standard errors
`variance(`*newvar*`)`	create *newvar* containing variances
`wald(`*newvar*`)`	create *newvar* containing the Wald test statistic
`p(`*newvar*`)`	create *newvar* containing the significance level (p-value) of the Wald test
`ci(`*newvars*`)`	create *newvars* containing lower and upper confidence intervals
`level(`#`)`	set confidence level; default is `level(95)`
`g(`*stub*`)`	create *stub*`1`, *stub*`2`, ..., *stub*`k` variables containing observation-specific derivatives
Advanced	
`iterate(`#`)`	maximum iterations for finding optimal step size; default is 100
`force`	calculate standard errors, etc., even when possibly inappropriate

Menu

Statistics > Postestimation > Nonlinear predictions

Description

`predictnl` calculates (possibly) nonlinear predictions after any Stata estimation command and optionally calculates the variances, standard errors, Wald test statistics, significance levels, and confidence limits for these predictions. Unlike its companion nonlinear postestimation commands `testnl` and `nlcom`, `predictnl` generates functions of the data (that is, predictions), not scalars. The quantities generated by `predictnl` are thus vectorized over the observations in the data.

Consider some general prediction, $g(\boldsymbol{\theta}, \mathbf{x}_i)$, for $i = 1, \ldots, n$, where $\boldsymbol{\theta}$ are the model parameters and $\mathbf{x}_i$ are some data for the ith observation; $\mathbf{x}_i$ is assumed fixed. Typically, $g(\boldsymbol{\theta}, \mathbf{x}_i)$ is estimated by $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$, where $\widehat{\boldsymbol{\theta}}$ are the estimated model parameters, which are stored in `e(b)` following any Stata estimation command.

In its most common use, `predictnl` generates two variables: one containing the estimated prediction, $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$, the other containing the estimated standard error of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$. The calculation of standard errors (and other obtainable quantities that are based on the standard errors, such as test statistics) is based on the delta method, an approximation appropriate in large samples; see *Methods and formulas*.

`predictnl` can be used with `svy` estimation results (assuming that `predict` is also allowed), see [SVY] **svy postestimation**.

The specification of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$ is handled by specifying *pnl_exp*, and the values of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$ are stored in the new variable *newvar* of storage type *type*. *pnl_exp* is any valid Stata expression and may also contain calls to two special functions unique to `predictnl`:

1. `predict(`[*predict_options*]`)`: When you are evaluating *pnl_exp*, `predict()` is a convenience function that replicates the calculation performed by the command

   ```
   predict ..., predict_options
   ```

   As such, the `predict()` function may be used either as a shorthand for the formula used to make this prediction or when the formula is not readily available. When used without arguments, `predict()` replicates the default prediction for that particular estimation command.

2. `xb(`[*eqno*]`)`: The `xb()` function replicates the calculation of the linear predictor $\mathbf{x}_i\mathbf{b}$ for equation *eqno*. If `xb()` is specified without *eqno*, the linear predictor for the first equation (or the only equation in single-equation estimation) is obtained.

   For example, `xb(#1)` (or equivalently, `xb()` with no arguments) translates to the linear predictor for the first equation, `xb(#2)` for the second, and so on. You could also refer to the equations by their names, such as `xb(income)`.

   When specifying *pnl_exp*, both of these functions may be used repeatedly, in combination, and in combination with other Stata functions and expressions. See *Remarks* for examples that use both of these functions.

Options

Main

`se(`*newvar*`)` adds *newvar* of storage type *type*, where for each `i` in the prediction sample, *newvar*`[i]` contains the estimated standard error of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$.

`variance(`*newvar*`)` adds *newvar* of storage type *type*, where for each `i` in the prediction sample, *newvar*`[i]` contains the estimated variance of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$.

`wald(`*newvar*`)` adds *newvar* of storage type *type*, where for each `i` in the prediction sample, *newvar*`[i]` contains the Wald test statistic for the test of the hypothesis $H_0\colon g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$.

`p(`*newvar*`)` adds *newvar* of storage type *type*, where *newvar*`[i]` contains the significance level (p-value) of the Wald test of $H_0\colon g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$ versus the two-sided alternative.

`ci(`*newvars*`)` requires the specification of two *newvars*, such that the ith observation of each will contain the left and right endpoints (respectively) of a confidence interval for $g(\boldsymbol{\theta}, \mathbf{x}_i)$. The level of the confidence intervals is determined by `level(#)`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`g(`*stub*`)` specifies that new variables, *stub*`1`, *stub*`2`, ..., *stub*`k` be created, where `k` is the dimension of $\boldsymbol{\theta}$. *stub*`1` will contain the observation-specific derivatives of $g(\boldsymbol{\theta}, \mathbf{x}_i)$ with respect to the first element, θ_1, of $\boldsymbol{\theta}$; *stub*`2` will contain the derivatives of $g(\boldsymbol{\theta}, \mathbf{x}_i)$ with respect to θ_2, etc.; If the derivative of $g(\boldsymbol{\theta}, \mathbf{x}_i)$ with respect to a particular coefficient in $\boldsymbol{\theta}$ equals zero for all observations in the prediction sample, the *stub* variable for that coefficient is not created. The ordering of the parameters in $\boldsymbol{\theta}$ is precisely that of the stored vector of parameter estimates `e(b)`.

Advanced

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of $g(\boldsymbol{\theta}, \mathbf{x}_i)$ with respect to $\boldsymbol{\theta}$. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

`force` forces the calculation of standard errors and other inference-related quantities in situations where `predictnl` would otherwise refuse to do so. The calculation of standard errors takes place by evaluating (at $\widehat{\boldsymbol{\theta}}$) the numerical derivative of $g(\boldsymbol{\theta}, \mathbf{x}_i)$ with respect to $\boldsymbol{\theta}$. If `predictnl` detects that $g()$ is possibly a function of random quantities other than $\widehat{\boldsymbol{\theta}}$, it will refuse to calculate standard errors or any other quantity derived from them. The `force` option forces the calculation to take place anyway. If you use the `force` option, there is no guarantee that any inference quantities (for example, standard errors) will be correct or that the values obtained can be interpreted.

Remarks

Remarks are presented under the following headings:

Introduction
Nonlinear transformations and standard errors
Using xb() and predict()
Multiple-equation (ME) estimators
Test statistics and significance levels
Manipulability
Confidence intervals

Introduction

`predictnl` and `nlcom` both use the delta method. They take a nonlinear transformation of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of this transformation. `nlcom` is designed for scalar functions of the parameters, and `predictnl` is designed for functions of the parameters and of the data, that is, for predictions.

Nonlinear transformations and standard errors

We begin by fitting a probit model to the low-birthweight data of Hosmer and Lemeshow (2000, 25). The data are described in detail in example 1 of [R] **logistic**.

```
. use http://www.stata-press.com/data/r12/lbw
(Hosmer & Lemeshow data)
. probit low lwt smoke ptl ht
Iteration 0:   log likelihood =   -117.336
Iteration 1:   log likelihood = -106.75886
Iteration 2:   log likelihood = -106.67852
Iteration 3:   log likelihood = -106.67851
Probit regression                                 Number of obs   =        189
                                                  LR chi2(4)      =      21.31
                                                  Prob > chi2     =     0.0003
Log likelihood = -106.67851                       Pseudo R2       =     0.0908
------------------------------------------------------------------------------

------------------------------------------------------------------------------
```

After we fit such a model, we first would want to generate the predicted probabilities of a low birthweight, given the covariate values in the estimation sample. This is easily done using `predict` after `probit`, but it doesn't answer the question, "What are the standard errors of those predictions?"

For the time being, we will consider ourselves ignorant of any automated way to obtain the predicted probabilities after `probit`. The formula for the prediction is

$$\Pr(y \neq 0|\mathbf{x}_i) = \Phi(\mathbf{x}_i\boldsymbol{\beta})$$

where Φ is the standard cumulative normal. Thus for this example, $g(\boldsymbol{\theta}, \mathbf{x}_i) = \Phi(\mathbf{x}_i\boldsymbol{\beta})$. Armed with the formula, we can use `predictnl` to generate the predictions and their standard errors:

```
. predictnl phat = normal(_b[_cons] + _b[ht]*ht + _b[ptl]*ptl +
> _b[smoke]*smoke + _b[lwt]*lwt), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/l
```

	phat	phat_se	lwt	smoke	ptl	ht
180.	.2363556	.042707	120	0	0	0
181.	.6577712	.1580714	154	0	1	1
182.	.2793261	.0519958	106	0	0	0
183.	.1502118	.0676338	190	1	0	0
184.	.5702871	.0819911	101	1	1	0
185.	.4477045	.079889	95	1	0	0
186.	.2988379	.0576306	100	0	0	0
187.	.4514706	.080815	94	1	0	0
188.	.5615571	.1551051	142	0	0	1
189.	.7316517	.1361469	130	1	0	1

Thus subject 180 in our data has an estimated probability of low birthweight of 23.6% with standard error 4.3%.

Used without options, `predictnl` is not much different from `generate`. By specifying the `se(phat_se)` option, we were able to obtain a variable containing the standard errors of the predictions; therein lies the utility of `predictnl`.

Using xb() and predict()

As was the case above, a prediction is often not a function of a few isolated parameters and their corresponding variables but instead is some (possibly elaborate) function of the entire linear predictor. For models with many predictors, the brute-force expression for the linear predictor can be cumbersome to type. An alternative is to use the inline function `xb()`. `xb()` is a shortcut for having to type `_b[_cons] + _b[ht]*ht + _b[ptl]*ptl + ...`,

```
. drop phat phat_se
. predictnl phat = normal(xb()), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/l
```

	phat	phat_se	lwt	smoke	ptl	ht
180.	.2363556	.042707	120	0	0	0
181.	.6577712	.1580714	154	0	1	1
182.	.2793261	.0519958	106	0	0	0
183.	.1502118	.0676338	190	1	0	0
184.	.5702871	.0819911	101	1	1	0
185.	.4477045	.079889	95	1	0	0
186.	.2988379	.0576306	100	0	0	0
187.	.4514706	.080815	94	1	0	0
188.	.5615571	.1551051	142	0	0	1
189.	.7316517	.1361469	130	1	0	1

which yields the same results. This approach is easier, produces more readable code, and is less prone to error, such as forgetting to include a term in the sum.

Here we used `xb()` without arguments because we have only one equation in our model. In multiple-equation (ME) settings, `xb()` (or equivalently `xb(#1)`) yields the linear predictor from the first equation, `xb(#2)` from the second, etc. You can also refer to equations by their names, for example, `xb(income)`.

❑ Technical note

Most estimation commands in Stata allow the postestimation calculation of linear predictors and their standard errors via `predict`. For example, to obtain these for the first (or only) equation in the model, you could type

```
predict xbvar, xb
predict stdpvar, stdp
```

Equivalently, you could type

```
predictnl xbvar = xb(), se(stdpvar)
```

but we recommend the first method, as it is faster. As we demonstrated above, however, `predictnl` is more general.

❑

Returning to our probit example, we can further simplify the calculation by using the inline function `predict()`. `predict(`*pred_options*`)` works by substituting, within our `predictnl` expression, the calculation performed by

```
predict ..., pred_options
```

In our example, we are interested in the predicted probabilities after a probit regression, normally obtained via

```
predict ..., p
```

We can obtain these predictions (and standard errors) by using

```
. drop phat phat_se
. predictnl phat = predict(p), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/l
```

	phat	phat_se	lwt	smoke	ptl	ht
180.	.2363556	.042707	120	0	0	0
181.	.6577712	.1580714	154	0	1	1
182.	.2793261	.0519958	106	0	0	0
183.	.1502118	.0676338	190	1	0	0
184.	.5702871	.0819911	101	1	1	0
185.	.4477045	.079889	95	1	0	0
186.	.2988379	.0576306	100	0	0	0
187.	.4514706	.080815	94	1	0	0
188.	.5615571	.1551051	142	0	0	1
189.	.7316517	.1361469	130	1	0	1

which again replicates what we have already done by other means. However, this version did not require knowledge of the formula for the predicted probabilities after a probit regression—`predict(p)` took care of that for us.

Because the predicted probability is the default prediction after `probit`, we could have just used `predict()` without arguments, namely,

```
. predictnl phat = predict(), se(phat_se)
```

Also, the expression *pnl_exp* can be inordinately complicated, with multiple calls to `predict()` and `xb()`. For example,

```
. predictnl phat = normal(invnormal(predict()) + predict(xb)/xb() - 1),
> se(phat_se)
```

is perfectly valid and will give the same result as before, albeit a bit inefficiently.

❑ Technical note

When using `predict()` and `xb()`, the *formula* for the calculation is substituted within *pnl_exp*, not the values that result from the application of that formula. To see this, note the subtle difference between

```
. predict xbeta, xb
. predictnl phat = normal(xbeta), se(phat_se)
```

and

```
. predictnl phat = normal(xb()), se(phat_se)
```

Both sequences will yield the same `phat`, yet for the first sequence, `phat_se` will equal zero for all observations. The reason is that, once evaluated, `xbeta` will contain the values of the linear predictor, yet these values are treated as fixed and nonstochastic as far as `predictnl` is concerned. By contrast, because `xb()` is shorthand for the formula used to calculate the linear predictor, it contains not values, but references to the estimated regression coefficients and corresponding variables. Thus the second method produces the desired result. ❑

Multiple-equation (ME) estimators

In [R] **mlogit**, data on insurance choice (Tarlov et al. 1989; Wells et al. 1989) were examined, and a multinomial logit was used to assess the effects of age, gender, race, and site of study (one of three sites) on the type of insurance:

```
. use http://www.stata-press.com/data/r12/sysdsn1, clear
(Health insurance data)
. mlogit insure age male nonwhite i.site, nolog
Multinomial logistic regression                 Number of obs   =        615
                                                LR chi2(10)     =      42.99
                                                Prob > chi2     =     0.0000
Log likelihood = -534.36165                     Pseudo R2       =     0.0387
```

Of particular interest is the estimation of the relative risk, which, for a given selection, is the ratio of the probability of making that selection to the probability of selecting the base category (`Indemnity` here), given a set of covariate values. In a multinomial logit model, the relative risk (when comparing to the base category) simplifies to the exponentiated linear predictor for that selection.

Using this example, we can estimate the observation-specific relative risks of selecting a prepaid plan over the base category (with standard errors) by either referring to the `Prepaid` equation by name or number,

```
. predictnl RRppaid = exp(xb(Prepaid)), se(SERRppaid)
```

or

```
. predictnl RRppaid = exp(xb(#1)), se(SERRppaid)
```

because `Prepaid` is the first equation in the model.

Those of us for whom the simplified formula for the relative risk does not immediately come to mind may prefer to calculate the relative risk directly from its definition, that is, as a ratio of two predicted probabilities. After `mlogit`, the predicted probability for a category may be obtained using `predict`, but we must specify the category as the outcome:

```
. predictnl RRppaid = predict(outcome(Prepaid))/predict(outcome(Indemnity)),
> se(SERRppaid)
(1 missing value generated)
. list RRppaid SERRppaid age male nonwhite site in 1/10
```

	RRppaid	SERRpp~d	age	male	nonwhite	site
1.	.6168578	.1503759	73.722107	0	0	2
2.	1.056658	.1790703	27.89595	0	0	2
3.	.8426442	.1511281	37.541397	0	0	1
4.	1.460581	.3671465	23.641327	0	1	3
5.	.9115747	.1324168	40.470901	0	0	2
6.	1.034701	.1696923	29.683777	0	0	2
7.	.9223664	.1344981	39.468857	0	0	2
8.	1.678312	.4216626	26.702255	1	0	1
9.	.9188519	.2256017	63.101974	0	1	3
10.	.5766296	.1334877	69.839828	0	0	1

The "(1 missing value generated)" message is not an error; further examination of the data would reveal that `age` is missing in one observation and that the offending observation (among others) is not in the estimation sample. Just as with `predict`, `predictnl` can generate predictions in or out of the estimation sample.

Thus we estimate (among other things) that a white, female, 73-year-old from site 2 is less likely to choose a prepaid plan over an indemnity plan—her relative risk is about 62% with standard error 15%.

Test statistics and significance levels

Often a standard error calculation is just a means to an end, and what is really desired is a test of the hypothesis,

$$H_0 : g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

versus the two-sided alternative.

We can use `predictnl` to obtain the Wald test statistics or significance levels (or both) for the above tests, whether or not we want standard errors. To obtain the Wald test statistics, we use the `wald()` option; for significance levels, we use `p()`.

Returning to our `mlogit` example, suppose that we wanted for each observation a test of whether the relative risk of choosing a prepaid plan over an indemnity plan is different from one. One way to do this would be to define $g()$ to be the relative risk minus one and then test whether $g()$ is different from zero.

```
. predictnl RRm1 = exp(xb(Prepaid)) - 1, wald(W_RRm1) p(sig_RRm1)
(1 missing value generated)
note: significance levels are with respect to the chi-squared(1) distribution.
. list RRm1 W_RRm1 sig_RRm1 age male nonwhite in 1/10
```

	RRm1	W_RRm1	sig_RRm1	age	male	nonwhite
1.	-.3831422	6.491778	.0108375	73.722107	0	0
2.	.0566578	.100109	.7516989	27.89595	0	0
3.	-.1573559	1.084116	.2977787	37.541397	0	0
4.	.4605812	1.573743	.2096643	23.641327	0	1
5.	-.0884253	.4459299	.5042742	40.470901	0	0
6.	.0347015	.0418188	.8379655	29.683777	0	0
7.	-.0776336	.3331707	.563798	39.468857	0	0
8.	.6783119	2.587788	.1076906	26.702255	1	0
9.	-.0811482	.1293816	.719074	63.101974	0	1
10.	-.4233705	10.05909	.001516	69.839828	0	0

The newly created variable `W_RRm1` contains the Wald test statistic for each observation, and `sig_RRm1` contains the level of significance. Thus our 73-year-old white female represented by the first observation would have a relative risk of choosing prepaid over indemnity that is significantly different from 1, at least at the 5% level. For this test, it was not necessary to generate a variable containing the standard error of the relative risk minus 1, but we could have done so had we wanted. We could have also omitted specifying `wald(W_RRm1)` if all we cared about were, say, the significance levels of the tests.

In this regard, `predictnl` acts as an observation-specific version of `testnl`, with the test results vectorized over the observations in the data. The significance levels are pointwise—they are not adjusted to reflect any simultaneous testing over the observations in the data.

Manipulability

There are many ways to specify $g(\boldsymbol{\theta}, \mathbf{x}_i)$ to yield tests such that, for multiple specifications of $g()$, the theoretical conditions for which

$$H_0 : g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

is true will be equivalent. However, this does not mean that the tests themselves will be equivalent. This is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] **boxcox**.

As an example, consider the previous section where we defined $g()$ to be the relative risk between choosing a prepaid plan over an indemnity plan, minus 1. We could also have defined $g()$ to be the risk difference—the probability of choosing a prepaid plan minus the probability of choosing an indemnity plan. Either specification of $g()$ yields a mathematically equivalent specification of $H_0 : g() = 0$; that is, the risk difference will equal zero when the relative risk equals one. However, the tests themselves do not give the same results:

```
. predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)),
> wald(W_RD) p(sig_RD)
(1 missing value generated)
note: significance levels are with respect to the chi-squared(1) distribution.
. list RD W_RD sig_RD RRm1 W_RRm1 sig_RRm1 in 1/10
```

	RD	W_RD	sig_RD	RRm1	W_RRm1	sig_RRm1
1.	-.2303744	4.230243	.0397097	-.3831422	6.491778	.0108375
2.	.0266902	.1058542	.7449144	.0566578	.100109	.7516989
3.	-.0768078	.9187646	.3377995	-.1573559	1.084116	.2977787
4.	.1710702	2.366535	.1239619	.4605812	1.573743	.2096643
5.	-.0448509	.4072922	.5233471	-.0884253	.4459299	.5042742
6.	.0165251	.0432816	.835196	.0347015	.0418188	.8379655
7.	-.0391535	.3077611	.5790573	-.0776336	.3331707	.563798
8.	.22382	4.539085	.0331293	.6783119	2.587788	.1076906
9.	-.0388409	.1190183	.7301016	-.0811482	.1293816	.719074
10.	-.2437626	6.151558	.0131296	-.4233705	10.05909	.001516

In certain cases (such as subject 8), the difference can be severe enough to potentially change the conclusion. The reason for this inconsistency is that the nonlinear Wald test is actually a standard Wald test of a first-order Taylor approximation of $g()$, and this approximation can differ according to how $g()$ is specified.

As such, keep in mind the manipulability of nonlinear Wald tests when drawing scientific conclusions.

Confidence intervals

We can also use `predictnl` to obtain confidence intervals for the observation-specific $g(\boldsymbol{\theta}, \mathbf{x}_i)$ by using the `ci()` option to specify two new variables to contain the left and right endpoints of the confidence interval, respectively. For example, we could generate confidence intervals for the risk differences calculated previously:

```
. drop RD
. predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)),
> ci(RD_lcl RD_rcl)
(1 missing value generated)
note: Confidence intervals calculated using Z critical values.
. list RD RD_lcl RD_rcl age male nonwhite in 1/10
```

	RD	RD_lcl	RD_rcl	age	male	nonwhite
1.	-.2303744	-.4499073	-.0108415	73.722107	0	0
2.	.0266902	-.1340948	.1874752	27.89595	0	0
3.	-.0768078	-.2338625	.080247	37.541397	0	0
4.	.1710702	-.0468844	.3890248	23.641327	0	1
5.	-.0448509	-.1825929	.092891	40.470901	0	0
6.	.0165251	-.1391577	.1722078	29.683777	0	0
7.	-.0391535	-.177482	.099175	39.468857	0	0
8.	.22382	.0179169	.4297231	26.702255	1	0
9.	-.0388409	-.2595044	.1818226	63.101974	0	1
10.	-.2437626	-.4363919	-.0511332	69.839828	0	0

The confidence level, here, 95%, is either set using the `level()` option or obtained from the current default level, `c(level)`; see [U] **20.7 Specifying the width of confidence intervals**.

From the above output, we can see that, for subjects 1, 8, and 10, a 95% confidence interval for the risk difference does not contain zero, meaning that, for these subjects, there is some evidence of a significant difference in risks.

The confidence intervals calculated by `predictnl` are pointwise; there is no adjustment (such as a Bonferroni correction) made so that these confidence intervals may be considered jointly at the specified level.

Methods and formulas

`predictnl` is implemented as an ado-file.

For the ith observation, consider the transformation $g(\boldsymbol{\theta}, \mathbf{x}_i)$, estimated by $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$, for the $1 \times k$ parameter vector $\boldsymbol{\theta}$ and data $\mathbf{x}_i$ ($\mathbf{x}_i$ is assumed fixed). The variance of $g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)$ is estimated by

$$\widehat{\text{Var}}\left\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\right\} = \mathbf{GVG}'$$

where $\mathbf{G}$ is the vector of derivatives

$$\mathbf{G} = \left\{ \left. \frac{\partial g(\boldsymbol{\theta}, \mathbf{x}_i)}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\widehat{\boldsymbol{\theta}}} \right\}_{(1\times k)}$$

and $\mathbf{V}$ is the estimated variance–covariance matrix of $\widehat{\boldsymbol{\theta}}$. Standard errors, $\widehat{\text{se}}\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\}$, are obtained as the square roots of the variances.

The Wald test statistic for testing

$$H_0 \colon g(\boldsymbol{\theta}, \mathbf{x}_i) = 0$$

versus the two-sided alternative is given by

$$W_i = \frac{\left\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\right\}^2}{\widehat{\text{Var}}\left\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\right\}}$$

When the variance–covariance matrix of $\widehat{\boldsymbol{\theta}}$ is an asymptotic covariance matrix, W_i is approximately distributed as χ^2 with 1 degree of freedom. For linear regression, W_i is taken to be approximately distributed as $F_{1,r}$, where r is the residual degrees of freedom from the original model fit. The levels of significance of the observation-by-observation tests of H_0 versus the two-sided alternative are given by

$$p_i = \Pr(T > W_i)$$

where T is either a χ^2- or F-distributed random variable, as described above.

A $(1-\alpha) \times 100\%$ confidence interval for $g(\boldsymbol{\theta}, \mathbf{x}_i)$ is given by

$$g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i) \pm z_{\alpha/2} \left[\widehat{\text{se}}\left\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\right\}\right]$$

when W_i is χ^2-distributed, and

$$g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i) \pm t_{\alpha/2,r} \left[\widehat{\text{se}}\left\{g(\widehat{\boldsymbol{\theta}}, \mathbf{x}_i)\right\}\right]$$

when W_i is F-distributed. z_p is the $1-p$ quantile of the standard normal distribution, and $t_{p,r}$ is the $1-p$ quantile of the t distribution with r degrees of freedom.

Title

probit — Probit regression

Syntax

```
probit depvar [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
offset(*varname*)	include *varname* in model with coefficient constrained to 1
asis	retain perfect predictor variables
constraints(*constraints*)	apply specified linear constraints
collinear	keep collinear variables
SE/Robust	
vce(*vcetype*)	*vcetype* may be oim, robust, cluster *clustvar*, bootstrap, or jackknife
Reporting	
level(#)	set confidence level; default is level(95)
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Maximization	
maximize_options	control the maximization process; seldom used
nocoef	do not display the coefficient table; seldom used
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, fracpoly, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] **11.1.10 Prefix commands**.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] **mi estimate**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce(), nocoef, and weights are not allowed with the svy prefix; see [SVY] **svy**.

fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

nocoef and coeflegend do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Binary outcomes > Probit regression

Description

probit fits a maximum-likelihood probit model.

If estimating on grouped data, see the bprobit command described in [R] **glogit**.

Several auxiliary commands may be run after probit, logit, or logistic; see [R] **logistic postestimation** for a description of these commands.

See [R] **logistic** for a list of related estimation commands.

Options

Model

noconstant, offset(*varname*), constraints(*constraints*), collinear; see [R] **estimation options**.

asis specifies that all specified variables and observations be retained in the maximization process. This option is typically not specified and may introduce numerical instability. Normally probit drops variables that perfectly predict success or failure in the dependent variable along with their associated observations. In those cases, the effective coefficient on the dropped variables is infinity (negative infinity) for variables that completely determine a success (failure). Dropping the variable and perfectly predicted observations has no effect on the likelihood or estimates of the remaining coefficients and increases the numerical stability of the optimization process. Specifying this option forces retention of perfect predictor variables and their associated observations.

SE/Robust

vce(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

Reporting

level(#); see [R] **estimation options**.

nocnsreport; see [R] **estimation options**.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Maximization

maximize_options: difficult, technique(*algorithm_spec*), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(*init_specs*); see [R] **maximize**. These options are seldom used.

The following options are available with probit but are not shown in the dialog box:

nocoef specifies that the coefficient table not be displayed. This option is sometimes used by programmers but is of no use interactively.

coeflegend; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Robust standard errors
Model identification

`probit` fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (more precisely, coded as 0 and not 0).

▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a probit model explaining whether a car is foreign based on its weight and mileage. Here is an overview of our data:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. keep make mpg weight foreign
. describe
Contains data from http://www.stata-press.com/data/r12/auto.dta
  obs:            74                          1978 Automobile Data
 vars:             4                          13 Apr 2011 17:45
 size:         1,702                           (_dta has notes)
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
make            str18  %-18s                  Make and Model
mpg             int    %8.0g                  Mileage (mpg)
weight          int    %8.0gc                 Weight (lbs.)
foreign         byte   %8.0g       origin     Car type
-------------------------------------------------------------------------------
Sorted by:  foreign
     Note:  dataset has changed since last saved
. inspect foreign
foreign:  Car type                              Number of Observations
------------------                                        ------------------------------
                                                Total   Integers   Nonintegers
|   #                       Negative              -          -          -
|   #                       Zero                 52         52          -
|   #                       Positive             22         22          -
|   #                                           ----       ----       ----
|   #   #                   Total                74         74          -
|   #   #                   Missing               -
+-----------------------                       ----
0                       1                     74
   (2 unique values)
      foreign is labeled and all values are documented in the label.
```

The `foreign` variable takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\texttt{foreign} = 1) = \Phi(\beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{mpg})$$

where Φ is the cumulative normal distribution.

To fit this model, we type

```
. probit foreign weight mpg
Iteration 0:   log likelihood =  -45.03321
Iteration 1:   log likelihood = -27.914626
  (output omitted)
Iteration 5:   log likelihood = -26.844189
Probit regression                                 Number of obs   =         74
                                                  LR chi2(2)      =      36.38
                                                  Prob > chi2     =     0.0000
Log likelihood = -26.844189                       Pseudo R2       =     0.4039

------------------------------------------------------------------------------
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0023355   .0005661    -4.13   0.000    -.003445   -.0012261
         mpg |  -.1039503   .0515689    -2.02   0.044    -.2050235   -.0028772
       _cons |   8.275464   2.554142     3.24   0.001     3.269437    13.28149
------------------------------------------------------------------------------
```

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

See [R] **maximize** for an explanation of the output.

◁

❑ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `probit` y x, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = \Phi(\mathbf{x}_j\boldsymbol{\beta})$$

where Φ is the standard cumulative normal.

❑

Robust standard errors

If you specify the `vce(robust)` option, `probit` reports robust standard errors; see [U] **20.20 Obtaining robust variance estimates**.

▷ Example 2

For the model from example 1, the robust calculation increases the standard error of the coefficient on `mpg` by almost 15%:

```
. probit foreign weight mpg, vce(robust) nolog
Probit regression                                 Number of obs   =         74
                                                  Wald chi2(2)    =      30.26
                                                  Prob > chi2     =     0.0000
Log pseudolikelihood = -26.844189                 Pseudo R2       =     0.4039

------------------------------------------------------------------------------
             |               Robust
     foreign |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      weight |  -.0023355   .0004934    -4.73   0.000    -.0033025   -.0013686
         mpg |  -.1039503   .0593548    -1.75   0.080    -.2202836    .0123829
       _cons |   8.275464   2.539177     3.26   0.001     3.298769    13.25216
------------------------------------------------------------------------------
```

Without vce(robust), the standard error for the coefficient on mpg was reported to be 0.052 with a resulting confidence interval of $[-0.21, -0.00]$.

◁

▷ Example 3

The vce(cluster *clustvar*) option can relax the independence assumption required by the probit estimator to independence between clusters. To demonstrate, we will switch to a different dataset.

We are studying unionization of women in the United States and have a dataset with 26,200 observations on 4,434 women between 1970 and 1988. We will use the variables age (the women were 14–26 in 1968, and our data span the age range of 16–46), grade (years of schooling completed, ranging from 0 to 18), not_smsa (28% of the person-time was spent living outside an SMSA—standard metropolitan statistical area), south (41% of the person-time was in the South), and year. Each of these variables is included in the regression as a covariate along with the interaction between south and year. This interaction, along with the south and year variables, is specified in the probit command using factor-variables notation, south##c.year. We also have variable union, indicating union membership. Overall, 22% of the person-time is marked as time under union membership, and 44% of these women have belonged to a union.

We fit the following model, ignoring that the women are observed an average of 5.9 times each in these data:

```
. use http://www.stata-press.com/data/r12/union, clear
(NLS Women 14-24 in 1968)
. probit union age grade not_smsa south##c.year
Iteration 0:   log likelihood =  -13864.23
Iteration 1:   log likelihood = -13545.541
Iteration 2:   log likelihood = -13544.385
Iteration 3:   log likelihood = -13544.385
Probit regression                                 Number of obs   =      26200
                                                  LR chi2(6)      =     639.69
                                                  Prob > chi2     =     0.0000
Log likelihood = -13544.385                       Pseudo R2       =     0.0231
------------------------------------------------------------------------------
       union |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         age |   .0118481   .0029072     4.08   0.000     .0061502     .017546
       grade |   .0267365   .0036689     7.29   0.000     .0195457    .0339273
    not_smsa |  -.1293525   .0202595    -6.38   0.000    -.1690604   -.0896445
    1.south |  -.8281077   .2472219    -3.35   0.001    -1.312654   -.3435618
        year |  -.0080931   .0033469    -2.42   0.016    -.0146529   -.0015333
             |
south#c.year |
          1  |   .0057369   .0030917     1.86   0.064    -.0003226    .0117965
             |
       _cons |  -.6542487   .2007777    -3.26   0.001    -1.047766   -.2607316
------------------------------------------------------------------------------
```

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, and so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a time trend for the south that is almost significantly different from the overall downward trend. The vce(cluster *clustvar*) option provides a way to fit this model and obtains correct standard errors:

```
. probit union age grade not_smsa south##c.year, vce(cluster id)
Iteration 0:   log pseudolikelihood =  -13864.23
Iteration 1:   log pseudolikelihood = -13545.541
Iteration 2:   log pseudolikelihood = -13544.385
Iteration 3:   log pseudolikelihood = -13544.385
Probit regression                                 Number of obs   =      26200
                                                  Wald chi2(6)    =     166.53
                                                  Prob > chi2     =     0.0000
Log pseudolikelihood = -13544.385                 Pseudo R2       =     0.0231
                              (Std. Err. adjusted for 4434 clusters in idcode)
------------------------------------------------------------------------------
             |               Robust
       union |      Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         age |   .0118481   .0056625     2.09   0.036     .0007499    .0229463
       grade |   .0267365   .0078124     3.42   0.001     .0114244    .0420486
    not_smsa |  -.1293525   .0403885    -3.20   0.001    -.2085125   -.0501925
     1.south |  -.8281077   .3201584    -2.59   0.010    -1.455607   -.2006089
        year |  -.0080931   .0060829    -1.33   0.183    -.0200153    .0038292
             |

```

The coefficient estimates are similar, but these standard errors are smaller than those produced by `probit, vce(cluster` *clustvar*`)`, as we would expect. If the equal-correlation assumption is valid, the population-averaged probit estimator above should be more efficient.

Is the assumption valid? That is a difficult question to answer. The default population-averaged estimates correspond to an assumption of exchangeable correlation within person. It would not be unreasonable to assume an AR(1) correlation within person or to assume that the observations are correlated but that we do not wish to impose any structure. See [XT] **xtprobit** and [XT] **xtgee** for full details.

◁

`probit, vce(cluster` *clustvar*`)` is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

Model identification

The `probit` command has one more feature that is probably the most useful. It will automatically check the model for identification and, if the model is underidentified, drop whatever variables and observations are necessary for estimation to proceed.

▷ Example 4

Have you ever fit a probit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

Outcome y	Independent variable x
0	1
0	1
0	0
1	0

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero when the independent variable is one. In our data, $\Pr(y = 0 \mid x = 1) = 1$, which means that the probit coefficient on x must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have many independent variables in your model. If you have ever had such difficulties, then you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that, at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. Meanwhile, you have been waiting. And the estimates that you finally receive, if any, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts you, fixes them, and then properly fits the model.

Let's return to our automobile data. Among the variables we have in the data is one called `repair` that takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
. use http://www.stata-press.com/data/r12/repair
(1978 Automobile Data)
. tabulate foreign repair
```

Car type	repair 1	2	3	Total
Domestic	10	27	9	46
Foreign	0	3	9	12
Total	10	30	18	58

All the cars with poor repair records (`repair` = 1) are domestic. If we were to attempt to predict `foreign` on the basis of the repair records, the predicted probability for the `repair` = 1 category would have to be zero. This in turn means that the probit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try using Stata on this problem.

```
. probit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
      1.repair dropped and 10 obs not used
Iteration 0:   log likelihood = -26.992087
Iteration 1:   log likelihood = -22.276479
Iteration 2:   log likelihood = -22.229184
Iteration 3:   log likelihood = -22.229138
Iteration 4:   log likelihood = -22.229138
Probit regression                                 Number of obs   =         48
                                                  LR chi2(1)      =       9.53
                                                  Prob > chi2     =     0.0020
Log likelihood = -22.229138                       Pseudo R2       =     0.1765
```

foreign	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
repair						
1	0	(empty)				
2	-1.281552	.4297326	-2.98	0.003	-2.123812	-.4392911
_cons	9.89e-17	.295409	0.00	1.000	-.578991	.578991

Remember that all the cars with poor repair records (`repair` = 1) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact "note: 1.repair != 0 predicts failure perfectly". This is Stata's mathematically precise way of saying what we said in English. When `repair` is 1, the car is domestic.

Stata then went on to say, "1.repair dropped and 10 obs not used". This is Stata eliminating the problem. First, `1.repair` had to be removed from the model because it would have an infinite coefficient. Then the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports "(empty)" in the row for `repair` = 1.

◁

❑ Technical note

Stata is pretty smart about catching these problems. It will catch "one-way causation by a dummy variable", as we demonstrated above.

Stata also watches for "two-way causation", that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says that the variable "predicts outcome perfectly" and stops. Statistics dictate that no model can be fit.

Stata also checks your data for collinear variables; it will say "so-and-so omitted because of collinearity". No observations need to be eliminated here and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model `age`, and if all the persons over 65 died within the year, Stata will say, "age $>$ 65 predicts failure perfectly". It will then inform us about how it resolves the issue and fit what can be fit of our model.

`probit` (and `logit`, `logistic`, and `ivprobit`) will also occasionally fail to converge and then display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

The cause of this message and what to do if you see it are described in [R] **logit**.

❑

Saved results

`probit` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(N_cds)`	number of completely determined successes
`e(N_cdf)`	number of completely determined failures
`e(k)`	number of parameters
`e(k_eq)`	number of equations in `e(b)`
`e(k_eq_model)`	number of equations in overall model test
`e(k_dv)`	number of dependent variables
`e(df_m)`	model degrees of freedom
`e(r2_p)`	pseudo-R-squared
`e(ll)`	log likelihood
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(chi2)`	χ^2
`e(p)`	significance of model test
`e(rank)`	rank of `e(V)`
`e(ic)`	number of iterations
`e(rc)`	return code
`e(converged)`	`1` if converged, `0` otherwise

Macros

e(cmd)	probit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(offset)	linear offset variable
e(chi2type)	Wald or LR; type of model χ^2 test
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(mns)	vector of means of the independent variables
e(rules)	information about perfect predictors
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample

Methods and formulas

probit is implemented as an ado-file.

Probit analysis originated in connection with bioassay, and the word probit, a contraction of "probability unit", was suggested by Bliss (1934a, 1934b). For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2010), Greene (2012), Long (1997), Pampel (2000), or Powers and Xie (2008). Long and Freese (2006, chap. 4) and Jones (2007, chap. 3) provide introductions to probit and logit, along with Stata examples.

The log-likelihood function for probit is

$$\ln L = \sum_{j \in S} w_j \ln \Phi(\mathbf{x}_j \boldsymbol{\beta}) + \sum_{j \notin S} w_j \ln\Big\{1 - \Phi(\mathbf{x}_j \boldsymbol{\beta})\Big\}$$

where Φ is the cumulative normal and w_j denotes the optional weights. $\ln L$ is maximized, as described in [R] **maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster` *clustvar*`)`, respectively. See [P] **_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. The scores are calculated as $\mathbf{u}_j = \{\phi(\mathbf{x}_j\mathbf{b})/\Phi(\mathbf{x}_j\mathbf{b})\}\mathbf{x}_j$ for the positive outcomes and $-[\phi(\mathbf{x}_j\mathbf{b})/\{1-\Phi(\mathbf{x}_j\mathbf{b})\}]\mathbf{x}_j$ for the negative outcomes, where ϕ is the normal density.

`probit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **variance estimation**.

Chester Ittner Bliss (1899–1979) was born in Ohio. He was educated as an entomologist, earning degrees from Ohio State and Columbia, and was employed by the United States Department of Agriculture until 1933. When he lost his job because of the Depression, Bliss then worked with R. A. Fisher in London and at the Institute of Plant Protection in Leningrad before returning to a post at the Connecticut Agricultural Experiment Station in 1938. He was also a lecturer at Yale for 25 years. Among many contributions to biostatistics, his development and application of probit methods to biological problems are outstanding.

Title

probit postestimation — Postestimation tools for probit

Description

The following postestimation commands are of special interest after `probit`:

Command	Description
`estat classification`	report various summary statistics, including the classification table
`estat gof`	Pearson or Hosmer–Lemeshow goodness-of-fit test
`lroc`	compute area under ROC curve and graph the curve
`lsens`	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate after the `svy` prefix.

For information about these commands, see [R] **logistic postestimation**.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

statistic	Description
Main	
pr	probability of a positive outcome; the default
xb	linear prediction
stdp	standard error of the linear prediction
* deviance	deviance residual
score	first derivative of the log likelihood with respect to $\mathbf{x}_j\boldsymbol{\beta}$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`deviance` calculates the deviance residual.

`score` calculates the equation-level score, $\partial \ln L/\partial(\mathbf{x}_j\boldsymbol{\beta})$.

`nooffset` is relevant only if you specified `offset(`*varname*`)` for `probit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

`asif` requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible using the estimated parameter from the model.

Remarks

Remarks are presented under the following headings:

Obtaining predicted values
Performing hypothesis tests

Obtaining predicted values

Once you have fit a probit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] **20 Estimation and postestimation commands** and [R] **predict**. Here we will make only a few additional comments.

`predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the linear combination $\mathbf{x}_j\mathbf{b}$, where $\mathbf{x}_j$ are the independent variables in the jth observation and $\mathbf{b}$ is the estimated parameter vector. This is known as the index function because the cumulative density indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations unless `rules` or `asif` is specified. This is covered in the following example.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data.

You can calculate the unadjusted-for-replicated-covariate-patterns diagonal elements of the hat matrix, or leverage, by typing

```
. predict pred
. predict stdp, stdp
. generate hat = stdp^2*pred*(1-pred)
```

▷ Example 1

In example 4 of [R] **probit**, we fit the probit model `probit foreign b3.repair`. To obtain predicted probabilities, we type

```
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
. summarize foreign p
```

Variable	Obs	Mean	Std. Dev.	Min	Max
foreign	58	.2068966	.4086186	0	1
p	48	.25	.1956984	.1	.5

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. In the previous example, `probit` dropped the variable `1.repair` from our model and excluded 10 observations. When we typed `predict p`, those same 10 observations were again excluded and their predictions set to missing.

`predict`'s `rules` option uses the rules in the prediction. During estimation, we were told, "1.repair != 0 predicts failure perfectly", so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
. summarize foreign p p2
```

Variable	Obs	Mean	Std. Dev.	Min	Max
foreign	58	.2068966	.4086186	0	1
p	48	.25	.1956984	.1	.5
p2	58	.2068966	.2016268	0	.5

`predict`'s `asif` option ignores the rules and the exclusion criteria and calculates predictions for all observations possible using the estimated parameters from the model:

```
. predict p3, asif
. summarize for p p2 p3
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
     foreign |         58    .2068966    .4086186         0          1
           p |         48         .25    .1956984        .1         .5
          p2 |         58    .2068966    .2016268         0         .5
          p3 |         58    .2931034    .2016268        .1         .5
```

Which is right? By default, `predict` uses the most conservative approach. If many observations had been excluded due to a simple rule, we could be reasonably certain that the `rules` prediction is correct. The `asif` prediction is correct only if the exclusion is a fluke and we would be willing to exclude the variable from the analysis, anyway. Then, however, we should refit the model to include the excluded observations. ◁

Performing hypothesis tests

After estimation with `probit`, you can perform hypothesis tests by using the `test` or `testnl` command; see [U] **20 Estimation and postestimation commands**.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

predict after probit

Let index j be used to index observations, not covariate patterns. Define M_j for each observation as the total number of observations sharing j's covariate pattern. Define Y_j as the total number of positive responses among observations sharing j's covariate pattern. Define p_j as the predicted probability of a positive outcome for observation j.

For $M_j > 1$, the deviance residual d_j is defined as

$$d_j = \pm\left(2\left[Y_j \ln\left(\frac{Y_j}{M_j p_j}\right) + (M_j - Y_j)\ln\left\{\frac{M_j - Y_j}{M_j(1-p_j)}\right\}\right]\right)^{1/2}$$

where the sign is the same as the sign of $(Y_j - M_j p_j)$. In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} -\sqrt{2M_j|\ln(1-p_j)|} & \text{if } Y_j = 0 \\ \sqrt{2M_j|\ln p_j|} & \text{if } Y_j = M_j \end{cases}$$

Title

proportion — Estimate proportions

Syntax

```
proportion varlist [if] [in] [weight] [, options]
```

options	Description
Model	
`stdize(`*varname*`)`	variable identifying strata for standardization
`stdweight(`*varname*`)`	weight variable for standardization
`nostdrescale`	do not rescale the standard weight variable
`nolabel`	suppress value labels from *varlist*
`missing`	treat missing values like other values
if/in/over	
`over(`*varlist*`[ , nolabel ])`	group over subpopulations defined by *varlist*; optionally, suppress group labels
SE/Cluster	
`vce(`*vcetype*`)`	*vcetype* may be `analytic`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`noheader`	suppress table header
`nolegend`	suppress table legend
display_options	control column formats and line width
`coeflegend`	display legend instead of statistics

`bootstrap`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.
`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Proportions

Description

`proportion` produces estimates of proportions, along with standard errors, for the categories identified by the values in each variable of *varlist*.

Options

Model

`stdize(`*varname*`)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(`*varname*`)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

`nolabel` specifies that value labels attached to the variables in *varlist* be ignored.

`missing` specifies that missing values in *varlist* be treated as valid categories, rather than omitted from the analysis (the default).

if/in/over

`over(`*varlist* [`, nolabel`]`)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist*.

When this option is supplied with one variable name, such as `over(`*varname*`)`, the value labels of *varname* are used to identify the subpopulations. If *varname* does not have labeled values (or there are unlabeled values), the values themselves are used, provided that they are nonnegative integers. Noninteger values, negative values, and labels that are not valid Stata names are substituted with a default identifier.

When `over()` is supplied with multiple variable names, each subpopulation is assigned a unique default identifier.

`nolabel` requests that value labels attached to the variables identifying the subpopulations be ignored.

SE/Cluster

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample proportion.

Reporting

`level(#)`; see [R] **estimation options**.

`noheader` prevents the table header from being displayed. This option implies `nolegend`.

`nolegend` prevents the table legend identifying the subpopulations from being displayed.

display_options: `cformat(%`*fmt*`)` and `nolstretch`; see [R] **estimation options**.

The following option is available with `proportion` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

▷ Example 1

We can estimate the proportion of each repair rating in the auto data:

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. proportion rep78
Proportion estimation                 Number of obs    =        69
```

	Proportion	Std. Err.	[95% Conf.	Interval]
rep78				
1	.0289855	.0203446	-.0116115	.0695825
2	.115942	.0388245	.0384689	.1934152
3	.4347826	.0601159	.3148232	.554742
4	.2608696	.0532498	.1546113	.3671278
5	.1594203	.0443922	.070837	.2480036

Here we use the `missing` option to include missing values as a category of `rep78`:

```
. proportion rep78, missing
Proportion estimation                 Number of obs    =        74
      _prop_6: rep78 = .
```

	Proportion	Std. Err.	[95% Conf.	Interval]
rep78				
1	.027027	.0189796	-.0107994	.0648534
2	.1081081	.0363433	.0356761	.1805401
3	.4054054	.0574637	.2908804	.5199305
4	.2432432	.0502154	.1431641	.3433224
5	.1486486	.0416364	.0656674	.2316299
_prop_6	.0675676	.0293776	.0090181	.1261171

◁

▷ Example 2

We can also estimate proportions over groups:

```
. proportion rep78, over(foreign)
Proportion estimation                Number of obs    =      69

       _prop_1: rep78 = 1
       _prop_2: rep78 = 2
       _prop_3: rep78 = 3
       _prop_4: rep78 = 4
       _prop_5: rep78 = 5
      Domestic: foreign = Domestic
       Foreign: foreign = Foreign
```

Over	Proportion	Std. Err.	[95% Conf.	Interval]
_prop_1				
Domestic	.0416667	.0291477	-.0164966	.0998299
Foreign	.	(no observations)		
_prop_2				
Domestic	.1666667	.0543607	.0581916	.2751417
Foreign	.	(no observations)		
_prop_3				
Domestic	.5625	.0723605	.4181069	.7068931
Foreign	.1428571	.0782461	-.0132805	.2989948
_prop_4				
Domestic	.1875	.0569329	.0738921	.3011079
Foreign	.4285714	.1106567	.2077595	.6493834
_prop_5				
Domestic	.0416667	.0291477	-.0164966	.0998299
Foreign	.4285714	.1106567	.2077595	.6493834

Saved results

`proportion` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(N_over)`	number of subpopulations
`e(N_stdize)`	number of standard strata
`e(N_clust)`	number of clusters
`e(k_eq)`	number of equations in `e(b)`
`e(df_r)`	sample degrees of freedom
`e(rank)`	rank of `e(V)`

Macros

`e(cmd)`	`proportion`
`e(cmdline)`	command as typed
`e(varlist)`	*varlist*
`e(stdize)`	*varname* from `stdize()`
`e(stdweight)`	*varname* from `stdweight()`
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(cluster)`	name of cluster variable

e(over)	*varlist* from over()
e(over_labels)	labels from over() variables
e(over_namelist)	names from e(over_labels)
e(namelist)	proportion identifiers
e(label#)	labels from #th variable in *varlist*
e(vce)	*vcetype* specified in vce()
e(vcetype)	title used to label Std. Err.
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(marginsnotok)	predictions disallowed by margins
Matrices	
e(b)	vector of proportion estimates
e(V)	(co)variance estimates
e(_N)	vector of numbers of nonmissing observations
e(_N_stdsum)	number of nonmissing observations within the standard strata
e(_p_stdize)	standardizing proportions
e(error)	error code corresponding to e(b)
Functions	
e(sample)	marks estimation sample

Methods and formulas

proportion is implemented as an ado-file.

Proportions are means of indicator variables; see [R] **mean**.

Title

proportion postestimation — Postestimation tools for proportion

Description

The following postestimation commands are available after `proportion`:

Command	Description
`estat`	VCE
`estat` (svy)	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

prtest — One- and two-sample tests of proportions

Syntax

One-sample test of proportion

```
prtest varname == #p [if] [in] [, level(#)]
```

Two-sample test of proportions

```
prtest varname1 == varname2 [if] [in] [, level(#)]
```

Two-group test of proportions

```
prtest varname [if] [in], by(groupvar) [level(#)]
```

Immediate form of one-sample test of proportion

```
prtesti #obs1 #p1 #p2 [, level(#) count]
```

Immediate form of two-sample test of proportions

```
prtesti #obs1 #p1 #obs2 #p2 [, level(#) count]
```

`by` is allowed with `prtest`; see [D] **by**.

immediate command: two-sample

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Two-sample proportion calculator

Description

`prtest` performs tests on the equality of proportions using large-sample statistics.

In the first form, `prtest` tests that *varname* has a proportion of $\#_p$. In the second form, `prtest` tests that $varname_1$ and $varname_2$ have the same proportion. In the third form, `prtest` tests that *varname* has the same proportion within the two groups defined by *groupvar*.

`prtesti` is the immediate form of `prtest`; see [U] **19 Immediate commands**.

The `bitest` command is a better version of the first form of `prtest` in that it gives exact p-values. Researchers should use `bitest` when possible, especially for small samples; see [R] **bitest**.

Options

Main

`by(`*groupvar*`)` specifies a numeric variable that contains the group information for a given observation. This variable must have only two values. Do not confuse the `by()` option with the `by` prefix; both may be specified.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`count` specifies that integer counts instead of proportions be used in the immediate forms of `prtest`. In the first syntax, `prtesti` expects that $\#_{\text{obs1}}$ and $\#_{p1}$ are counts—$\#_{p1} \leq \#_{\text{obs1}}$—and $\#_{p2}$ is a proportion. In the second syntax, `prtesti` expects that all four numbers are integer counts, that $\#_{\text{obs1}} \geq \#_{p1}$, and that $\#_{\text{obs2}} \geq \#_{p2}$.

Remarks

The `prtest` output follows the output of `ttest` in providing a lot of information. Each proportion is presented along with a confidence interval. The appropriate one- or two-sample test is performed, and the two-sided and both one-sided results are included at the bottom of the output. For a two-sample test, the calculated difference is also presented with its confidence interval. This command may be used for both large-sample testing and large-sample interval estimation.

▷ Example 1: One-sample test of proportion

In the first form, `prtest` tests whether the mean of the sample is equal to a known constant. Assume that we have a sample of 74 automobiles. We wish to test whether the proportion of automobiles that are foreign is different from 40%.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. prtest foreign == .4
One-sample test of proportion                 foreign: Number of obs =       74
------------------------------------------------------------------------------
    Variable |       Mean   Std. Err.                     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     foreign |   .2972973   .0531331                      .1931583    .4014363
------------------------------------------------------------------------------
    p = proportion(foreign)                                       z =  -1.8034
Ho: p = 0.4

     Ha: p < 0.4                 Ha: p != 0.4                 Ha: p > 0.4
 Pr(Z < z) = 0.0357         Pr(|Z| > |z|) = 0.0713          Pr(Z > z) = 0.9643
```

The test indicates that we cannot reject the hypothesis that the proportion of foreign automobiles is 0.40 at the 5% significance level.

◁

▷ Example 2: Two-sample test of proportions

We have two headache remedies that we give to patients. Each remedy's effect is recorded as 0 for failing to relieve the headache and 1 for relieving the headache. We wish to test the equality of the proportion of people relieved by the two treatments.

```
. use http://www.stata-press.com/data/r12/cure
. prtest cure1 == cure2
Two-sample test of proportions                  cure1: Number of obs =       50
                                                cure2: Number of obs =       59
------------------------------------------------------------------------------
    Variable |       Mean   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
       cure1 |         .52   .0706541                      .3815205    .6584795
       cure2 |   .7118644   .0589618                      .5963013    .8274275
-------------+----------------------------------------------------------------
        diff |  -.1918644   .0920245                     -.372229   -.0114998
             |  under Ho:   .0931155    -2.06   0.039
------------------------------------------------------------------------------
       diff = prop(cure1) - prop(cure2)                          z =  -2.0605
   Ho: diff = 0

   Ha: diff < 0                 Ha: diff != 0                 Ha: diff > 0
 Pr(Z < z) = 0.0197         Pr(|Z| < |z|) = 0.0394          Pr(Z > z) = 0.9803
```

We find that the proportions are statistically different from each other at any level greater than 3.9%.

◁

▷ Example 3: Immediate form of one-sample test of proportion

`prtesti` is like `prtest`, except that you specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the proportion of registered voters among 50 randomly selected eligible voters as 0.52. We wish to test whether the proportion is 0.7:

```
. prtesti 50 .52 .70
One-sample test of proportion                       x: Number of obs =       50
------------------------------------------------------------------------------
    Variable |       Mean   Std. Err.                      [95% Conf. Interval]
-------------+----------------------------------------------------------------
           x |         .52   .0706541                      .3815205    .6584795
------------------------------------------------------------------------------
       p = proportion(x)                                         z =  -2.7775
Ho: p = 0.7

    Ha: p < 0.7                  Ha: p != 0.7                  Ha: p > 0.7
 Pr(Z < z) = 0.0027         Pr(|Z| > |z|) = 0.0055          Pr(Z > z) = 0.9973
```

◁

▷ Example 4: Immediate form of two-sample test of proportions

To judge teacher effectiveness, we wish to test whether the same proportion of people from two classes will answer an advanced question correctly. In the first classroom of 30 students, 40% answered the question correctly, whereas in the second classroom of 45 students, 67% answered the question correctly.

```
. prtesti 30 .4 45 .67
Two-sample test of proportions                     x: Number of obs =       30
                                                   y: Number of obs =       45
------------------------------------------------------------------------------
    Variable |       Mean   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
           x |         .4   .0894427                      .2246955    .5753045
           y |        .67   .0700952                       .532616     .807384
-------------+----------------------------------------------------------------
        diff |       -.27   .1136368                     -.4927241   -.0472759
             |  under Ho:   .1169416    -2.31   0.021
------------------------------------------------------------------------------
        diff = prop(x) - prop(y)                                  z =  -2.3088
    Ho: diff = 0

    Ha: diff < 0                 Ha: diff != 0                 Ha: diff > 0
 Pr(Z < z) = 0.0105         Pr(|Z| < |z|) = 0.0210          Pr(Z > z) = 0.9895
```

◁

Saved results

`prtest` and `prtesti` save the following in `r()`:

Scalars

`r(z)`	z statistic	`r(N_#)`	number of observations for variable #
`r(P_#)`	proportion for variable #		

Methods and formulas

`prtest` and `prtesti` are implemented as ado-files.

See Acock (2010, 149–155) for additional examples of tests of proportions using Stata.

A large-sample $100(1-\alpha)\%$ confidence interval for a proportion p is

$$\widehat{p} \pm z_{1-\alpha/2}\sqrt{\frac{\widehat{p}\,\widehat{q}}{n}}$$

and a $100(1-\alpha)\%$ confidence interval for the difference of two proportions is given by

$$(\widehat{p}_1 - \widehat{p}_2) \pm z_{1-\alpha/2}\sqrt{\frac{\widehat{p}_1\widehat{q}_1}{n_1} + \frac{\widehat{p}_2\widehat{q}_2}{n_2}}$$

where $\widehat{q} = 1 - \widehat{p}$ and z is calculated from the inverse cumulative standard normal distribution.

The one-tailed and two-tailed tests of a population proportion use a normally distributed test statistic calculated as

$$z = \frac{\widehat{p} - p_0}{\sqrt{p_0 q_0 / n}}$$

where p_0 is the hypothesized proportion. A test of the difference of two proportions also uses a normally distributed test statistic calculated as

$$z = \frac{\widehat{p}_1 - \widehat{p}_2}{\sqrt{\widehat{p}_p \widehat{q}_p (1/n_1 + 1/n_2)}}$$

where

$$\widehat{p}_p = \frac{x_1 + x_2}{n_1 + n_2}$$

and x_1 and x_2 are the total number of successes in the two populations.

Title

pwcompare — Pairwise comparisons

Syntax

`pwcompare` *marginlist* [`,` *options*]

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results or `_eqns` to reference equations. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

```
. pwcompare i.sex i.group i.sex#i.group
. pwcompare sex group sex#group
. pwcompare sex##group
```

options	Description
Main	
`mcompare(`*method*`)`	adjust for multiple comparisons; default is `mcompare(noadjust)`
`asobserved`	treat all factor variables as observed
Equations	
`equation(`*eqspec*`)`	perform comparisons within equation *eqspec*
`atequations`	perform comparisons within each equation
Advanced	
`emptycells(`*empspec*`)`	treatment of empty cells for balanced factors
`noestimcheck`	suppress estimability checks
Reporting	
`level(#)`	confidence level; default is `level(95)`
`cieffects`	show effects table with confidence intervals; the default
`pveffects`	show effects table with p-values
`effects`	show effects table with confidence intervals and p-values
`cimargins`	show table of margins and confidence intervals
`groups`	show table of margins and group codes
`sort`	sort the margins or contrasts within each term
`post`	post margins and their VCEs as estimation results
display_options	control column formats, line width, and suppress blank lines between terms
eform_option	report exponentiated contrasts

method	Description
noadjust	do not adjust for multiple comparisons; the default
bonferroni [adjustall]	Bonferroni's method; adjust across all terms
sidak [adjustall]	Šidák's method; adjust across all terms
scheffe	Scheffé's method
* tukey	Tukey's method
* snk	Student–Newman–Keuls' method
* duncan	Duncan's method
* dunnett	Dunnett's method

* tukey, snk, duncan, and dunnett are only allowed with results from anova, manova, regress, and mvreg. tukey, snk, duncan, and dunnett are not allowed with results from svy.

Time-series operators are allowed if they were used in the estimation.

Menu

Statistics > Postestimation > Pairwise comparisons

Description

pwcompare performs pairwise comparisons across the levels of factor variables from the most recently fit model. pwcompare can compare estimated cell means, marginal means, intercepts, marginal intercepts, slopes, or marginal slopes—collectively called margins. pwcompare reports the comparisons as contrasts (differences) of margins along with significance tests or confidence intervals for the contrasts. The tests and confidence intervals can be adjusted for multiple comparisons.

pwcompare can be used with svy estimation results; see [SVY] **svy postestimation**.

See [R] **margins, pwcompare** for performing pairwise comparisons of margins of linear and nonlinear predictions.

Options

Main

mcompare(*method*) specifies the method for computing p-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, α_c, to achieve a prespecified experimentwise error rate, α_e.

mcompare(noadjust) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m\alpha_c$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the m comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the F (or χ^2) distribution with degrees of freedom equal to the rank of the term.

For results from `anova`, `regress`, `manova`, and `mvreg` (see [R] **anova**, [R] **regress**, [MV] **manova**, and [R] **mvreg**), `pwcompare` allows the following additional methods. These methods are not allowed with results that used `vce(robust)` or `vce(cluster` *clustvar*`)`.

`mcompare(tukey)` uses what is commonly referred to as Tukey's honestly significant difference. This method uses the Studentized range distribution instead of the t distribution.

`mcompare(snk)` is a variation on `mcompare(tukey)` that counts only the number of margins in the range for a given comparison instead of the full number of margins.

`mcompare(duncan)` is a variation on `mcompare(snk)` with additional adjustment to the significance probabilities.

`mcompare(dunnett)` uses Dunnett's method for making comparisons with a reference category.

`mcompare(`*method* `adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginlist*. This option is compatible only with the `bonferroni` and `sidak` methods.

`asobserved` specifies that factor covariates be evaluated using the cell frequencies observed when the model was fit. The default is to treat all factor covariates as though there were an equal number of observations at each level.

Equations

`equation(`*eqspec*`)` specifies the equation from which margins are to be computed. The default is to compute margins from the first equation.

`atequations` specifies that the margins be computed within each equation.

Advanced

`emptycells(`*empspec*`)` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced.

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margins estimable but changes their interpretation.

`noestimcheck` specifies that `pwcompare` not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**. The significance level used by the `groups` option is $100 - \#$, expressed as a percentage.

`cieffects` specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, and p-values be reported.

`effects` specifies that a table of the pairwise comparisons with their standard errors, test statistics, p-values, and confidence intervals be reported.

`cimargins` specifies that a table of the margins with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted on the margins or differences in each term.

`post` causes `pwcompare` to behave like a Stata estimation (e-class) command. `pwcompare` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations.

display_options: `vsquish`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`cformat(%`*fmt*`)` specifies how to format contrasts or margins, standard errors, and confidence limits in the table of pairwise comparisons.

`pformat(%`*fmt*`)` specifies how to format p-values in the table of pairwise comparisons.

`sformat(%`*fmt*`)` specifies how to format test statistics in the table of pairwise comparisons.

`nolstretch` specifies that the width of the table of pairwise comparisons not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of pairwise comparisons up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

eform_option specifies that the contrasts table be displayed in exponentiated form. e^{contrast} is displayed rather than contrast. Standard errors and confidence intervals are also transformed. See [R] ***eform_option*** for the list of available options.

Remarks

`pwcompare` performs pairwise comparisons of margins across the levels of factor variables from the most recently fit model. The margins can be estimated cell means, marginal means, intercepts, marginal intercepts, slopes, or marginal slopes. With the exception of slopes, we can also consider these margins to be marginal linear predictions.

The margins are calculated as linear combinations of the coefficients. Let k be the number of levels for a factor term in our model; then there are k margins for that term, and

$$m = \binom{k}{2} = \frac{k(k-1)}{2}$$

unique pairwise comparisons of those margins.

The confidence intervals and p-values for these pairwise comparisons can be adjusted to account for multiple comparisons. Bonferroni's, Šidák's, and Scheffé's adjustments can be made for multiple comparisons after fitting any type of model. In addition, Tukey's, Student–Newman–Keuls', Duncan's, and Dunnett's adjustments are available when fitting ANOVA, linear regression, MANOVA, or multivariate regression models.

Pairwise comparisons of means

Suppose we are interested in the effects of five different fertilizers on wheat yield. We could estimate the following linear regression model to determine the effect of each type of fertilizer on the yield.

```
. use http://www.stata-press.com/data/r12/yield
(Artificial wheat yield dataset)
. regress yield i.fertilizer
```

Source	SS	df	MS	Number of obs =	200
				F(4, 195) =	5.33
Model	1078.84207	4	269.710517	Prob > F =	0.0004
Residual	9859.55334	195	50.561812	R-squared =	0.0986
				Adj R-squared =	0.0801
Total	10938.3954	199	54.9668111	Root MSE =	7.1107

yield	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
fertilizer						
2	3.62272	1.589997	2.28	0.024	.4869212	6.758518
3	.4906299	1.589997	0.31	0.758	-2.645169	3.626428
4	4.922803	1.589997	3.10	0.002	1.787005	8.058602
5	-1.238328	1.589997	-0.78	0.437	-4.374127	1.89747
_cons	41.36243	1.124298	36.79	0.000	39.14509	43.57977

In this simple case, the coefficients for fertilizers 2 through 5 indicate the difference in the mean yield for that fertilizer versus the mean yield for fertilizer 1. That the standard errors of all four coefficients are identical results from having perfectly balanced data.

Marginal means

We can use `pwcompare` with the `cimargins` option to compute the mean yield for each of the fertilizers.

```
. pwcompare fertilizer, cimargins
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Margin	Std. Err.	Unadjusted [95% Conf.	Interval]
fertilizer				
1	41.36243	1.124298	39.14509	43.57977
2	44.98515	1.124298	42.7678	47.20249
3	41.85306	1.124298	39.63571	44.0704
4	46.28523	1.124298	44.06789	48.50258
5	40.1241	1.124298	37.90676	42.34145

Looking at the confidence intervals for fertilizers 1 and 2 in the table above, we might be tempted to conclude that these means are not significantly different because the intervals overlap. However, as discussed in *Interaction plots* of [R] **marginsplot**, we cannot draw conclusions about the differences in means by looking at confidence intervals for the means themselves. Instead, we would need to look at confidence intervals for the difference in means.

All pairwise comparisons

By default, `pwcompare` calculates all pairwise differences of the margins, in this case pairwise differences of the mean yields.

```
. pwcompare fertilizer
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Contrast	Std. Err.	Unadjusted [95% Conf.	Interval]
fertilizer				
2 vs 1	3.62272	1.589997	.4869212	6.758518
3 vs 1	.4906299	1.589997	-2.645169	3.626428
4 vs 1	4.922803	1.589997	1.787005	8.058602
5 vs 1	-1.238328	1.589997	-4.374127	1.89747
3 vs 2	-3.13209	1.589997	-6.267889	.0037086
4 vs 2	1.300083	1.589997	-1.835715	4.435882
5 vs 2	-4.861048	1.589997	-7.996847	-1.725249
4 vs 3	4.432173	1.589997	1.296375	7.567972
5 vs 3	-1.728958	1.589997	-4.864757	1.406841
5 vs 4	-6.161132	1.589997	-9.29693	-3.025333

If a confidence interval does not include zero, the means for the compared fertilizers are significantly different. Therefore, at the 5% significance level, we would reject the hypothesis that the means for fertilizers 1 and 2 are equivalent—as we would do for `4 vs 1`, `5 vs 2`, `4 vs 3`, and `5 vs 4`.

We may prefer to see the p-values instead of looking at confidence intervals to determine whether the pairwise differences are significantly different from zero. We could use the `pveffects` option to see the differences with standard errors and p-values, or we could use the `effects` option to see both p-values and confidence intervals in the same table. Here we specify `effects` as well as the `sort` option so that the differences are sorted from smallest to largest.

```
. pwcompare fertilizer, effects sort
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Contrast	Std. Err.	Unadjusted t	Unadjusted P>|t|	Unadjusted [95% Conf.	Interval]

4 vs 2	1.300083	1.589997	0.82	0.415	-1.835715	4.435882
2 vs 1	3.62272	1.589997	2.28	0.024	.4869212	6.758518
4 vs 3	4.432173	1.589997	2.79	0.006	1.296375	7.567972
4 vs 1	4.922803	1.589997	3.10	0.002	1.787005	8.058602

We find that 5 of the 10 pairs of means are significantly different at the 5% significance level.

We can use the `groups` option to obtain a table that identifies groups whose means are not significantly different by assigning them the same letter.

```
. pwcompare fertilizer, groups sort
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Margin	Std. Err.	Unadjusted Groups
fertilizer			
5	40.1241	1.124298	A
1	41.36243	1.124298	A
3	41.85306	1.124298	AB
2	44.98515	1.124298	BC
4	46.28523	1.124298	C

```
Note: Margins sharing a letter in the group label
      are not significantly different at the 5%
      level.
```

The letter A that is assigned to fertilizers 5, 1, and 3 designates that the mean yields for these fertilizers are not different at the 5% level.

Overview of multiple-comparison methods

For a single test, if we choose a 5% significance level, we would have a 5% chance of concluding that two margins are different when the population values are actually equal. This is known as making a type I error. When we perform $m = k(k-1)/2$ pairwise comparisons of the k margins, we have m opportunities to make a type I error.

pwcompare with the mcompare() option allows us to adjust the confidence intervals and p-values for each comparison to account for the increased probability of making a type I error when making multiple comparisons. Bonferroni's adjustment, Šidák's adjustment, and Scheffé's adjustment can be used when making pairwise comparisons of the margins after any estimation command. Tukey's honestly significant difference, Student–Newman–Keuls' method, Duncan's method, and Dunnett's method are only available when fitting linear models after anova, manova, regress, or mvreg.

Fisher's protected least-significant difference (LSD)

pwcompare does not offer an mcompare() option specifically for Fisher's protected least-significant difference (LSD). In this methodology, no adjustment is made to the confidence intervals or p-values. However, it is protected in the sense that no pairwise comparisons are tested unless the joint test for the corresponding term in the model is significant. Therefore, the default mcompare(noadjust) corresponds to Fisher's protected LSD assuming that the corresponding joint test was performed before using pwcompare.

Milliken and Johnson (2009) recommend using this methodology for planned comparisons, assuming the corresponding joint test is significant.

Bonferroni's adjustment

mcompare(bonferroni) adjusts significance levels based on the Bonferroni inequality, which, in the case of multiple testing, tells us that the maximum error rate for all comparisons is the sum of the error rates for the individual comparisons. Assuming that we are using the same significance level for all tests, the experimentwise error rate is the error rate for a single test multiplied by the

number of comparisons. Therefore, a p-value for each comparison can be computed by multiplying the unadjusted p-value by the total number of comparisons. If the adjusted p-value is greater than 1, then `pwcompare` will report a p-value of 1.

Bonferroni's adjustment is popular because it is easy to compute manually and because it can be applied to any set of tests, not only the pairwise comparisons available in `pwcompare`. In addition, this method does not require equal sample sizes.

Because Bonferroni's adjustment is so general, it is more conservative than many of the other adjustments. It is especially conservative when a large number of tests is being performed.

Šidák's adjustment

`mcompare(sidak)` performs an adjustment using Šidák's method. This adjustment, like Bonferroni's adjustment, is derived from an inequality. However, in this case, the inequality is based on the probability of not making a type I error. For a single test, the probability that we do not make a type I error is $1 - \alpha$. For two independent tests, both using α as a significance level, the probability is $(1 - \alpha)(1 - \alpha)$. Likewise, for m independent tests, the probability of not making a type I error is $(1 - \alpha)^m$. Therefore, the probability of making one or more type I errors is $1 - (1 - \alpha)^m$. When tests are not independent, the probability of making at least one error is less than $1 - (1 - \alpha)^m$. Therefore, we can compute an adjusted p-value as $1 - (1 - {}_up)^m$, where ${}_up$ is the unadjusted p-value for a single comparison.

Šidák's method is also conservative although slightly less so than Bonferroni's method. Like Bonferroni's method, this method does not require equal sample sizes.

Scheffé's adjustment

Scheffé's adjustment is used when `mcompare(scheffe)` is specified. This adjustment is derived from the joint F test and its correspondence to the maximum normalized comparison. To adjust for multiple comparisons, the absolute value of the t statistic for a particular comparison can be compared with a critical value of $\sqrt{(k-1)F_{k-1,\nu}}$, where ν is the residual degrees of freedom. $F_{k-1,\nu}$ is the distribution of the joint F test for the corresponding term in a one-way ANOVA model. Winer, Brown, and Michels (1991, 191–195) discuss this in detail. For estimation commands that report z statistics instead of t statistics for the tests on coefficients, a χ^2 distribution is used instead of an F distribution.

Scheffé's method allows for making all possible comparisons of the k margins, not just the pairwise comparisons. Unlike the methods described above, it does not take into account the number of comparisons that are currently being made. Therefore, this method is even more conservative than the others. Because this method adjusts for all possible comparisons of the levels of the term, Milliken and Johnson (2009) recommend using this procedure when making unplanned contrasts that are suggested by the data. As Winer, Brown, and Michels (1991, 191) put it, this method is often used to adjust for "unfettered data snooping". When using this adjustment, a contrast will never be significant if the joint F or χ^2 test for the term is not also significant.

This is another method that does not require equal sample sizes.

Tukey's HSD adjustment

Tukey's adjustment is also referred to as Tukey's honestly significant difference (HSD) and is used when `mcompare(tukey)` is specified. It is often applied to all pairwise comparisons of means. Tukey's HSD is commonly used as a post hoc test although this is not a requirement.

To adjust for multiple comparisons, Tukey's method compares the absolute value of the t statistic from the individual comparison with a critical value based on a Studentized range distribution with parameter equal to the number of levels in the term. When applied to pairwise comparisons of means,

$$q = \frac{\text{mean}_{\max} - \text{mean}_{\min}}{s}$$

follows a Studentized range distribution with parameter k and ν degrees of freedom. Here $\text{mean}_{\max}$ and $\text{mean}_{\min}$ are the largest and smallest marginal means, and s is an estimate of the standard error of the means.

Now for the comparison of the smallest and largest means, we can say that the probability of not making a type I error is

$$\Pr\left(\frac{\text{mean}_{\max} - \text{mean}_{\min}}{s} \leq q_{k,\nu}\right) = 1 - \alpha$$

Then the following inquality holds for all pairs of means simultaneously:

$$\Pr\left(\frac{|\text{mean}_i - \text{mean}_j|}{s} \leq q_{k,\nu}\right) \geq 1 - \alpha$$

Based on this procedure, Tukey's HSD computes the p-value for each of the individual comparisons using the Studentized range distribution. However, because the equality holds only for the difference in the largest and smallest means, this procedure produces conservative tests for the remaining comparisons. Winer, Brown, and Michels (1991, 172–182) discuss this in further detail.

Tukey's HSD requires equal sample sizes.

Student–Newman–Keuls' adjustment

The Student–Newman–Keuls (SNK) method is used when `mcompare(snk)` is specified. It is a modification to Tukey's method and is less conservative. In this procedure, we first order the means. We then test the difference in the smallest and largest means using a critical value from the Studentized range distribution with parameter k, where k is the number of levels in the term. This step uses the same methodology as in Tukey's procedure. However, in the next step, we will then test for differences in the two sets of means that are the endpoints of the two ranges including $k - 1$ means. Specifically, we test the difference in the smallest mean and the second-largest mean using a critical value from the Studentized range distribution with parameter $k - 1$. We would also test the difference in the second-smallest mean and the largest mean using this critical value. Likewise, the means that are the endpoints of ranges including $k - 2$ means when ordered are tested using the Studentized range distribution with parameter $k - 2$, and so on.

As with Tukey's method, equal sample sizes are required.

Duncan's adjustment

When `mcompare(duncan)` is specified, tests are adjusted for multiple comparisons using Duncan's method, which is sometimes referred to as Duncan's new multiple range method. This adjustment produces tests that are less conservative than both Tukey's HSD and SNK. This procedure is performed in the same manner as SNK except that the p-values for the individual comparisons are adjusted as $1-(1-{}_{\text{snk}}p_i)^{1/(r+1)}$, where ${}_{\text{snk}}p$ is the p-value computed using the SNK method and r represents the number of means that, when ordered, fall between the two that are being compared.

Again equal sample sizes are required for this adjustment.

Dunnett's adjustment

Dunnett's adjustment is obtained by specifying `mcompare(dunnett)`. It is used when one of the levels of a factor can be considered a control or reference level with which each of the other levels is being compared. When Dunnett's adjustment is requested, $k-1$ instead of $k(k-1)/2$ pairwise comparisons are made. Dunnett (1955, 1964) developed tables of critical values for what Miller (1981, 76) refers to as the "many-one t statistic". The t statistics for individual comparisons are compared with these critical values when making many comparisons to a single reference level.

This method also requires equal sample sizes.

Example adjustments using one-way models

Fisher's protected LSD

Fisher's protected LSD requires that we first verify that the joint test for a term in our model is significant before proceeding with pairwise comparisons. Using our previous example, we could have first used the `contrast` command to obtain a joint test for the effects of fertilizer.

```
. contrast fertilizer
Contrasts of marginal linear predictions
Margins      : asbalanced
```

	df	F	P>F
fertilizer	4	5.33	0.0004
Residual	195		

This test for the effects of fertilizer is highly significant. Now we can say we are using Fisher's protected LSD when looking at the unadjusted p-values that were obtained from our previous command,

```
. pwcompare fertilizer, effects sort
```

Tukey's HSD

Because we fit a linear regression model and are interested in all pairwise comparisons of the marginal means, we may instead choose to use Tukey's HSD.

```
. pwcompare fertilizer, effects sort mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer	10

	Contrast	Std. Err.	Tukey t	Tukey P>|t|	Tukey [95% Conf.	Interval]
fertilizer						
5 vs 4	-6.161132	1.589997	-3.87	0.001	-10.53914	-1.78312
5 vs 2	-4.861048	1.589997	-3.06	0.021	-9.239059	-.4830368
3 vs 2	-3.13209	1.589997	-1.97	0.285	-7.510101	1.245921
5 vs 3	-1.728958	1.589997	-1.09	0.813	-6.106969	2.649053
5 vs 1	-1.238328	1.589997	-0.78	0.936	-5.616339	3.139683
3 vs 1	.4906299	1.589997	0.31	0.998	-3.887381	4.868641
4 vs 2	1.300083	1.589997	0.82	0.925	-3.077928	5.678095
2 vs 1	3.62272	1.589997	2.28	0.156	-.7552913	8.000731
4 vs 3	4.432173	1.589997	2.79	0.046	.0541623	8.810185
4 vs 1	4.922803	1.589997	3.10	0.019	.5447922	9.300815

This time, our p-values have been modified, and we find that only four of the pairwise differences are considered significantly different from zero at the 5% level.

If we only are interested in performing pairwise comparisons of a subset of our means, we can use factor-variable operators to select the levels of the factor that we want to compare. Here we exclude all comparisons involving fertilizer 1.

```
. pwcompare i(2/5).fertilizer, effects sort mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer	6

	Contrast	Std. Err.	Tukey t	Tukey P>|t|	Tukey [95% Conf.	Interval]
fertilizer						
5 vs 4	-6.161132	1.589997	-3.87	0.001	-10.28133	-2.040937
5 vs 2	-4.861048	1.589997	-3.06	0.013	-8.981242	-.7408538
3 vs 2	-3.13209	1.589997	-1.97	0.203	-7.252284	.9881042
5 vs 3	-1.728958	1.589997	-1.09	0.698	-5.849152	2.391236
4 vs 2	1.300083	1.589997	0.82	0.846	-2.820111	5.420278
4 vs 3	4.432173	1.589997	2.79	0.030	.3119792	8.552368

The adjusted p-values and confidence intervals differ from those in the previous output because Tukey's adjustment takes into account the total number of comparisons being made when determining the appropriate degrees of freedom to use for the Studentized range distribution.

Dunnett's method for comparisons to a control

If one of our five fertilizer groups represents fields where no fertilizer was applied, we may want to use Dunnett's method to compare each of the four fertilizers with the control group. In this case, we make only $k - 1$ comparisons for k groups.

```
. pwcompare fertilizer, effects mcompare(dunnett)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer	4

	Contrast	Std. Err.	Dunnett t	Dunnett P>|t|	Dunnett [95% Conf.	Interval]
fertilizer						
2 vs 1	3.62272	1.589997	2.28	0.079	-.2918331	7.537273
3 vs 1	.4906299	1.589997	0.31	0.994	-3.423923	4.405183
4 vs 1	4.922803	1.589997	3.10	0.008	1.00825	8.837356
5 vs 1	-1.238328	1.589997	-0.78	0.852	-5.152881	2.676225

In our previous `regress` command, fertilizer 1 was treated as the base. Therefore, by default, it was treated as the control when using Dunnett's adjustment, and the pairwise comparisons are equivalent to the coefficients reported by `regress`. Based on our `regress` output, we would conclude that fertilizers 2 and 4 are different from fertilizer 1 at the 5% level. However, using Dunnett's adjustment, we find only fertilizer 4 to be different from fertilizer 1 at this same significance level.

If the model is fit without a base level for a factor variable, then `pwcompare` will choose the first level as the reference level. If we want to make comparisons with a different level than the one `mcompare(dunnett)` chooses by default, we can use the `b.` operator to override the default. Here we use fertilizer 5 as the reference level.

```
. pwcompare b5.fertilizer, effects sort mcompare(dunnett)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

4 vs 5	6.161132	1.589997	3.87	0.001	2.246579	10.07568

Two-way models

In the previous examples, we have performed pairwise comparisons after fitting a model with a single factor. Now we include two factors and their interaction in our model.

```
. regress yield fertilizer##irrigation
```

Source	SS	df	MS

_cons	36.91257	1.116571	33.06	0.000	34.7101	39.11504

We can perform pairwise comparisons of the cell means defined by the fertilizer and irrigation interaction.

```
. pwcompare fertilizer#irrigation, sort groups mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer#irrigation	45

	Margin	Std. Err.	Tukey Groups
fertilizer#irrigation			
5 0	35.69507	1.116571	A
3 0	36.34383	1.116571	A
1 0	36.91257	1.116571	AB
2 0	38.79482	1.116571	AB
4 0	41.81757	1.116571	BC
5 1	44.55313	1.116571	CD
1 1	45.81229	1.116571	CDE
3 1	47.36229	1.116571	DEF
4 1	50.7529	1.116571	EF
2 1	51.17547	1.116571	F

```
Note: Margins sharing a letter in the group label are
      not significantly different at the 5% level.
```

Based on Tukey's HSD and a 5% significance level, we would conclude that the mean yield for fertilizer 5 without irrigation is not significantly different from the mean yields for fertilizers 1, 2, and 3 when used without irrigation but is significantly different from the remaining means.

Up to this point, most of the pairwise comparisons that we have performed could have also been obtained with `pwmean` (see [R] **pwmean**) if we had not been interested in examining the results from the estimation command before making pairwise comparisons of the means. For instance, we could reproduce the results from the above `pwcompare` command by typing

```
. pwmean yield, over(fertilizer irrigation) sort group mcompare(tukey)
```

However, `pwcompare` extends the capabilities of `pwmean` in many ways. For instance, `pwmean` only allows for pairwise comparisons of the cell means determined by the highest level interaction of the variables specified in the `over()` option. However, `pwcompare` allows us to fit a single model, such as the two-way model that we fit above,

```
. regress yield fertilizer##irrigation
```

and compute pairwise comparisons of the marginal means for only one of the variables in the model:

```
. pwcompare fertilizer, sort effects mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer	10

	Contrast	Std. Err.	Tukey t	Tukey P>|t|	Tukey [95% Conf.	Interval]
fertilizer						
5 vs 4	-6.161132	1.116571	-5.52	0.000	-9.236338	-3.085925
5 vs 2	-4.861048	1.116571	-4.35	0.000	-7.936255	-1.785841
3 vs 2	-3.13209	1.116571	-2.81	0.044	-6.207297	-.0568832
5 vs 3	-1.728958	1.116571	-1.55	0.532	-4.804165	1.346249
5 vs 1	-1.238328	1.116571	-1.11	0.802	-4.313535	1.836879
3 vs 1	.4906299	1.116571	0.44	0.992	-2.584577	3.565837
4 vs 2	1.300083	1.116571	1.16	0.772	-1.775123	4.37529
2 vs 1	3.62272	1.116571	3.24	0.012	.5475131	6.697927
4 vs 3	4.432173	1.116571	3.97	0.001	1.356967	7.50738
4 vs 1	4.922803	1.116571	4.41	0.000	1.847597	7.99801

Here the standard errors for the differences in marginal means and the residual degrees of freedom are based on the full model. Therefore, the results will differ from those obtained from `pwcompare` after fitting the one-way model with only `fertilizer` (or equivalently using `pwmean`).

Pairwise comparisons of slopes

If we fit a model with a factor variable that is interacted with a continuous variable, `pwcompare` will even allow us to make pairwise comparisons of the slopes of the continuous variable for the levels of the factor variable.

In this case, we have a continuous variable, `NO3_N`, indicating the amount of nitrate nitrogen already existing in the soil, based on a sample taken from each field.

```
. regress yield fertilizer##c.NO3_N
```

Source	SS	df	MS		
Model	7005.69932	9	778.411035	Number of obs =	200

4	-2.97627	.9136338	-3.26	0.001	-4.778438	-1.174102
5	-3.275947	.8247385	-3.97	0.000	-4.902767	-1.649127
_cons	-5.459168	7.638241	-0.71	0.476	-20.52581	9.607477

These are the pairwise differences of the slopes of NO3_N for each pair of fertilizers:

```
. pwcompare fertilizer#c.NO3_N, pveffects sort mcompare(scheffe)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
fertilizer#c.NO3_N	10

	Contrast	Std. Err.	Scheffe t	Scheffe P>|t|
fertilizer#c.NO3_N				
5 vs 1	-3.275947	.8247385	-3.97	0.004
4 vs 1	-2.97627	.9136338	-3.26	0.034
5 vs 3	-2.270237	.4691771	-4.84	0.000
5 vs 2	-1.993909	.4550851	-4.38	0.001
4 vs 3	-1.97056	.612095	-3.22	0.038
4 vs 2	-1.694232	.6013615	-2.82	0.099
2 vs 1	-1.282039	.8953419	-1.43	0.727
3 vs 1	-1.00571	.9025862	-1.11	0.871
5 vs 4	-.2996772	.4900939	-0.61	0.984
3 vs 2	.276328	.5844405	0.47	0.994

Using Scheffé's adjustment, we find that five of the pairs have significantly different slopes at the 5% level.

Nonlinear models

pwcompare can also perform pairwise comparisons of the marginal linear predictions after fitting a nonlinear model. For instance, we can use the dataset from *Beyond linear models* in [R] **contrast** and fit the following logistic regression model of patient satisfaction on hospital:

```
. use http://www.stata-press.com/data/r12/hospital
(Artificial hospital satisfaction data)
. logit satisfied i.hospital
Iteration 0:   log likelihood = -393.72216
Iteration 1:   log likelihood = -387.55736
Iteration 2:   log likelihood =  -387.4768
Iteration 3:   log likelihood = -387.47679
Logistic regression                             Number of obs   =        802
                                                LR chi2(2)      =      12.49
                                                Prob > chi2     =     0.0019
Log likelihood = -387.47679                     Pseudo R2       =     0.0159
```

satisfied	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
hospital						
2	.5348129	.2136021	2.50	0.012	.1161604	.9534654
3	.7354519	.2221929	3.31	0.001	.2999618	1.170942
_cons	1.034708	.1391469	7.44	0.000	.7619855	1.307431

For this model, the marginal linear predictions are the predicted log odds for each hospital and can be obtained with the cimargins option:

```
. pwcompare hospital, cimargins
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Margin	Std. Err.	Unadjusted [95% Conf.	Interval]
hospital				
1	1.034708	.1391469	.7619855	1.307431
2	1.569521	.1620618	1.251886	1.887157
3	1.77016	.1732277	1.43064	2.10968

The pairwise comparisons are, therefore, differences in the log odds. We can specify mcompare(bonferroni) and effects to request Bonferroni-adjusted p-values and confidence intervals.

```
. pwcompare hospital, effects mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
satisfied	
hospital	3

	Contrast	Std. Err.	Bonferroni z	Bonferroni P>|z|	Bonferroni [95% Conf.	Interval]
satisfied						
hospital						
2 vs 1	.5348129	.2136021	2.50	0.037	.0234537	1.046172
3 vs 1	.7354519	.2221929	3.31	0.003	.2035265	1.267377
3 vs 2	.200639	.2372169	0.85	1.000	-.3672535	.7685314

For nonlinear models, only Bonferroni's adjustment, Šidák's adjustment, and Scheffé's adjustment are available.

If we want pairwise comparisons reported as odds ratios, we can specify the `or` option.

```
. pwcompare hospital, effects mcompare(bonferroni) or
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
satisfied	
hospital	3

	Odds Ratio	Std. Err.	Bonferroni z	Bonferroni P>|z|	Bonferroni [95% Conf.	Interval]
satisfied						
hospital						
2 vs 1	1.707129	.3646464	2.50	0.037	1.023731	2.846733
3 vs 1	2.086425	.4635888	3.31	0.003	1.225718	3.551525
3 vs 2	1.222183	.2899226	0.85	1.000	.6926341	2.156597

Notice that these tests are still performed on the marginal linear predictions. The odds ratios reported here are the exponentiated versions of the pairwise differences of log odds in the previous output. For further discussion, see [R] **contrast**.

Multiple-equation models

`pwcompare` works with models containing multiple equations. Commands such as `intreg` and `gnbreg` allow their ancillary parameters to be modeled as a function of independent variables, and `pwcompare` can compare the margins within these equations. The `equation()` option can be used to specify the equation for which pairwise comparisons of the margins should be made. The `atequations` option specifies that pairwise comparisons be computed for each equation. In addition, `pwcompare` allows a special pseudofactor for equation—called `_eqns`—when working with results from `manova`, `mvreg`, `mlogit`, and `mprobit`.

Here we use the jaw fracture dataset described in example 4 of [MV] **manova**. We fit a multivariate regression model including one independent factor variable, `fracture`.

```
. use http://www.stata-press.com/data/r12/jaw
(Table 4.6 Two-Way Unbalanced Data for Fractures of the Jaw -- Rencher (1998))
. mvreg y1 y2 y3 = i.fracture
```

Equation	Obs	Parms	RMSE	"R-sq"	F	P
y1	27	3	10.42366	0.2966	5.060804	0.0147
y2	27	3	6.325398	0.1341	1.858342	0.1777
y3	27	3	5.976973	0.1024	1.368879	0.2735

	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
y1						
fracture						
2	-8.833333	4.957441	-1.78	0.087	-19.06499	1.398322
3	6	5.394759	1.11	0.277	-5.134235	17.13423
_cons	37	3.939775	9.39	0.000	28.8687	45.1313
y2						
fracture						
2	-5.761905	3.008327	-1.92	0.067	-11.97079	.446977
3	-3.053571	3.273705	-0.93	0.360	-9.810166	3.703023
_cons	38.42857	2.390776	16.07	0.000	33.49425	43.36289
y3						
fracture						
2	4.261905	2.842618	1.50	0.147	-1.60497	10.12878
3	.9285714	3.093377	0.30	0.767	-5.455846	7.312989
_cons	58.57143	2.259083	25.93	0.000	53.90891	63.23395

`pwcompare` performs pairwise comparisons of the margins using the coefficients from the first equation by default:

```
. pwcompare fracture, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
y1	
fracture	3

	Contrast	Std. Err.	Bonferroni [95% Conf.	Interval]
y1				
fracture				
2 vs 1	-8.833333	4.957441	-21.59201	3.925341
3 vs 1	6	5.394759	-7.884173	19.88417
3 vs 2	14.83333	4.75773	2.588644	27.07802

We can use the equation() option to get pwcompare to perform comparisons in the y2 equation:

```
. pwcompare fracture, equation(y2) mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
y2	
fracture	3

	Contrast	Std. Err.	Bonferroni [95% Conf.	Interval]
y2				
fracture				
2 vs 1	-5.761905	3.008327	-13.50426	1.980449
3 vs 1	-3.053571	3.273705	-11.47891	5.371769
3 vs 2	2.708333	2.887136	-4.722119	10.13879

Because we are working with mvreg results, we can use the _eqns pseudofactor to compare the margins between the three dependent variables. The levels of _eqns index the equations: 1 for the first equation, 2 for the second, and 3 for the third.

```
. pwcompare _eqns, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Number of Comparisons
_eqns	3

	Contrast	Std. Err.	Bonferroni [95% Conf.	Interval]
_eqns				
2 vs 1	-.5654762	2.545923	-7.117768	5.986815
3 vs 1	24.24603	2.320677	18.27344	30.21862
3 vs 2	24.81151	2.368188	18.71664	30.90637

For the previous command, the only methods available are mcompare(bonferroni), mcompare(sidak), or mcompare(scheffe). Methods that use the Studentized range are not appropriate for making comparisons across equations.

Unbalanced data

pwcompare treats all factors as balanced when it computes the marginal means. By "balanced", we mean that the number of observations in each combination of factor levels (in each cell mean) is equal. We can alternatively specify the asobserved option when we have unbalanced data to obtain marginal means that are based on the observed cell frequencies from the model fit. For more details on the difference in these two types of marginal means and a discussion of when each may be appropriate, see [R] **margins** and [R] **contrast**.

In addition, when our data are not balanced, some of the multiple-comparison adjustments are no longer appropriate. Tukey's method, Student–Newman–Keuls' method, Duncan's method, and Dunnett's method assume equal numbers of observations per group.

Here we use an unbalanced dataset and fit a two-way ANOVA model for cholesterol levels on race and age group. Then we perform pairwise comparisons of the mean cholesterol levels for each race, requesting Šidák's adjustment as well as marginal means that are computed using the observed cell frequencies.

```
. use http://www.stata-press.com/data/r12/cholesterol3
(Artificial cholesterol data, unbalanced)
. anova chol race##agegrp
                          Number of obs =      67     R-squared     =  0.8179

Empty cells

An empty cell is a combination of the levels of factor variables that is not observed in the estimation sample. When we have empty cells in our data, the marginal means involving those empty cells are not estimable as described in [R] **margins**. In addition, all pairwise comparisons involving a marginal mean that is not estimable are themselves not estimable. Here we use a dataset where we do not have any observations for white individuals in the 20–29 age group. We can use the `emptycells(reweight)` option to reweight the nonempty cells so that we can estimate the marginal mean for whites and compute pairwise comparisons involving that marginal mean.

```
. use http://www.stata-press.com/data/r12/cholesterol2
(Artificial cholesterol data, empty cells)
. tabulate race agegrp
```

race	agegrp					Total

race				
2 vs 1	2.922769	2.841166	-2.768769	8.614308
3 vs 1	-4.12621	2.678677	-9.492244	1.239824
3 vs 2	-7.048979	2.841166	-12.74052	-1.35744

For further details on the `emptycells(reweight)` option, see [R] **margins** and [R] **contrast**.

Saved results

pwcompare saves the following in r():

Scalars

r(df_r)	variance degrees of freedom, from e(df_r)
r(k_terms)	number of terms in *marginlist*
r(level)	confidence level of confidence intervals
r(balanced)	1 if fully balanced data; 0 otherwise

Macros

r(cmd)	pwcompare
r(cmdline)	command as typed
r(est_cmd)	e(cmd) from original estimation results
r(est_cmdline)	e(cmdline) from original estimation results
r(title)	title in output
r(emptycells)	*empspec* from emptycells()
r(groups#)	group codes for the #th margin in r(b)
r(mcmethod_vs)	*method* from mcompare()
r(mctitle_vs)	title for *method* from mcompare()
r(mcadjustall_vs)	adjustall or empty
r(margin_method)	asbalanced or asobserved
r(vce)	*vcetype* specified in vce() in original estimation command

Matrices

r(b)	margin estimates
r(V)	variance–covariance matrix of the margin estimates
r(error)	margin estimability codes; 0 means estimable, 8 means not estimable
r(table)	matrix containing the margins with their standard errors, test statistics, p-values, and confidence intervals
r(M)	matrix that produces the margins from the model coefficients
r(b_vs)	margin difference estimates
r(V_vs)	variance–covariance matrix of the margin difference estimates
r(error_vs)	margin difference estimability codes; 0 means estimable, 8 means not estimable
r(table_vs)	matrix containing the margin differences with their standard errors, test statistics, p-values, and confidence intervals
r(L)	matrix that produces the margin differences from the model coefficients
r(k_groups)	number of significance groups for each term

pwcompare with the post option also saves the following in e():

Scalars

e(df_r)	variance degrees of freedom, from e(df_r)
e(k_terms)	number of terms in *marginlist*
e(balanced)	1 if fully balanced data; 0 otherwise

Macros

e(error_vs)	margin difference estimability codes; 0 means estimable, 8 means not estimable
e(L)	matrix that produces the margin differences from the model coefficients
e(k_groups)	number of significance groups for each term

Methods and formulas

pwcompare is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Notation
Unadjusted comparisons
Bonferroni's method
Šidák's method
Scheffé's method
Tukey's method
Student–Newman–Keuls' method
Duncan's method
Dunnett's method

Notation

pwcompare performs comparisons of margins; see *Methods and formulas* in [R] **contrast**.

If there are k margins for a given factor term, then there are

$$m = \binom{k}{2} = \frac{k(k-1)}{2}$$

unique pairwise comparisons. Let the ith pairwise comparison be denoted by

$$\widehat{\delta}_i = l_i'\mathbf{b}$$

where $\mathbf{b}$ is a column vector of coefficients from the fitted model and l_i is a column vector that forms the corresponding linear combination. If $\widehat{\mathbf{V}}$ denotes the estimated variance matrix for $\mathbf{b}$, then the standard error for $\widehat{\delta}_i$ is given by

$$\widehat{\mathrm{se}}(\widehat{\delta}_i) = \sqrt{l_i'\widehat{\mathbf{V}}l_i}$$

The corresponding test statistic is then

$$t_i = \frac{\widehat{\delta}_i}{\widehat{\mathrm{se}}(\widehat{\delta}_i)}$$

and the limits for a $100(1-\alpha)\%$ confidence interval for the expected value of $\widehat{\delta}_i$ are

$$\widehat{\delta}_i \pm c_i(\alpha)\,\widehat{\mathrm{se}}(\widehat{\delta}_i)$$

where $c_i(\alpha)$ is the critical value corresponding to the chosen multiple-comparison method.

Unadjusted comparisons

`pwcompare` computes unadjusted p-values and confidence intervals by default. `pwcompare` uses the t distribution with $\nu =$ `e(df_r)` degrees of freedom when `e(df_r)` is posted by the estimation command. The unadjusted two-sided p-value is

$${}_up_i = 2\Pr(t_\nu > |t_i|)$$

and the unadjusted critical value ${}_uc_i(\alpha)$ satisfies the following probability statement:

$$\alpha = 2\Pr\{t_\nu > {}_uc_i(\alpha)\}$$

`pwcompare` uses the standard normal distribution when `e(df_r)` is not posted.

Bonferroni's method

For `mcompare(bonferroni)`, the adjusted p-value is

$${}_bp_i = \min(1, m\,{}_up_i)$$

and the adjusted critical value is

$${}_bc_i(\alpha) = {}_uc_i(\alpha/m)$$

Šidák's method

For `mcompare(sidak)`, the adjusted p-value is

$$_{\text{si}}p_i = 1 - (1 - {}_u p_i)^m$$

and the adjusted critical value is

$$_{\text{si}}c_i(\alpha) = {}_u c_i\left\{1 - (1-\alpha)^{1/m}\right\}$$

Scheffé's method

For `mcompare(scheffe)`, the adjusted p-value is

$$_{\text{sc}}p_i = \Pr\left(F_{d,\nu} > t_i^2/d\right)$$

where $F_{d,\nu}$ is distributed as an F with d numerator and ν denominator degrees of freedom and d is the rank of the VCE for the term. The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr\left[F_{d,\nu} > \{{}_{\text{sc}}c_i(\alpha)\}^2/d\right]$$

`pwcompare` uses the χ^2 distribution when `e(df_r)` is not posted.

Tukey's method

For `mcompare(tukey)`, the adjusted p-value is

$$_t p_i = \Pr\left(q_{k,\nu} > |t_i|\sqrt{2}\right)$$

where $q_{k,\nu}$ is distributed as the Studentized range statistic for k means and ν residual degrees of freedom (Miller 1981). The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr\left\{q_{k,\nu} > {}_t c_i(\alpha)\sqrt{2}\right\}$$

Student–Newman–Keuls' method

For `mcompare(snk)`, suppose t_i is comparing two margins that have r other margins between them. Then the adjusted p-value is

$$_{\text{snk}}p_i = \Pr\left(q_{r+2,\nu} > |t_i|\sqrt{2}\right)$$

where r ranges from 0 to $k-2$. The adjusted critical value $_{\text{snk}}c_i(\alpha)$ satisfies the following probability statement:

$$\alpha = \Pr\left\{q_{r+2,\nu} > {}_{\text{snk}}c_i(\alpha)\sqrt{2}\right\}$$

Duncan's method

For `mcompare(duncan)`, the adjusted p-value is

$$_{\text{dunc}}p_i = 1 - (1 - {}_{\text{snk}}p_i)^{1/(r+1)}$$

and the adjusted critical value is

$$_{\text{dunc}}c_i(\alpha) = {}_{\text{snk}}c_i\left\{1 - (1-\alpha)^{r+1}\right\}$$

Dunnett's method

For `mcompare(dunnett)`, the margins are compared with a reference category, resulting in only $k-1$ pairwise comparisons. The adjusted p-value is

$$_{\text{dunn}}p_i = \Pr(d_{k-1,\nu} > |t_i|)$$

where $d_{k-1,\nu}$ is distributed as the many-one t statistic (Miller 1981, 76). The adjusted critical value $_{\text{dunn}}c_i(\alpha)$ satisfies the following probability statement:

$$\alpha = \Pr\left\{d_{k-1,\nu} > {}_{\text{dunn}}c_i(\alpha)\right\}$$

The multiple-comparison methods for `mcompare(tukey)`, `mcompare(snk)`, `mcompare(duncan)`, and `mcompare(dunnett)` assume the normal distribution with equal variance and sample size for each marginal mean; thus these methods are allowed only with results from `anova`, `regress`, `manova`, and `mvreg`. These options will cause `pwcompare` to report a footnote if unbalanced factors are detected.

Title

pwcompare postestimation — Postestimation tools for pwcompare

Description

The following postestimation commands are available after `pwcompare, post`:

Command	Description
`estat`	VCE; `estat vce` only
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Remarks

When we use the `post` option with `pwcompare`, the marginal linear predictions are posted as estimation results, and we can use postestimation commands to perform further analysis on them.

In *Pairwise comparisons of means* of [R] **pwcompare**, we fit a regression of wheat yield on types of fertilizers.

```
. use http://www.stata-press.com/data/r12/yield
(Artificial wheat yield dataset)
. regress yield i.fertilizer
  (output omitted)
```

We also used `pwcompare` with the `cimargins` option to obtain the marginal mean yield for each fertilizer. We can add the `post` option to this command to post these marginal means and their VCEs as estimation results.

```
. pwcompare fertilizer, cimargins post
Pairwise comparisons of marginal linear predictions
Margins      : asbalanced
```

	Margin	Std. Err.	Unadjusted [95% Conf.	Interval]
fertilizer				
1	41.36243	1.124298	39.14509	43.57977
2	44.98515	1.124298	42.7678	47.20249
3	41.85306	1.124298	39.63571	44.0704
4	46.28523	1.124298	44.06789	48.50258
5	40.1241	1.124298	37.90676	42.34145

Now we can use `nlcom` to compute a percentage improvement in the mean yield for fertilizer 2 when compared with fertilizer 1.

```
. nlcom (pct_chg: 100*(_b[2.fertilizer] - _b[1.fertilizer])/_b[1.fertilizer])
     pct_chg:  100*(_b[2.fertilizer] - _b[1.fertilizer])/_b[1.fertilizer]
```

	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
pct_chg	8.758479	4.015932	2.18	0.030	.838243	16.67872

The mean yield for fertilizer 2 is about 9% higher than that of fertilizer 1, with a standard error of 4%.

Title

pwmean — Pairwise comparisons of means

Syntax

`pwmean` *varname*`, over(`*varlist*`)` [*options*]

options	Description
Main	
* `over(`*varlist*`)`	compare means across each combination of the levels in *varlist*
`mcompare(`*method*`)`	adjust for multiple comparisons; default is `mcompare(noadjust)`
Reporting	
`level(#)`	confidence level; default is `level(95)`
`cieffects`	display a table of mean differences and confidence intervals; the default
`pveffects`	display a table of mean differences and p-values
`effects`	display a table of mean differences with p-values and confidence intervals
`cimeans`	display a table of means and confidence intervals
`groups`	display a table of means with codes that group them with other means that are not significantly different
`sort`	sort results tables by displayed mean or difference
display_options	control column formats and line width

* `over(`*varlist*`)` is required.

method	Description
`noadjust`	do not adjust for multiple comparisons; the default
`bonferroni`	Bonferroni's method
`sidak`	Šidák's method
`scheffe`	Scheffé's method
`tukey`	Tukey's method
`snk`	Student–Newman–Keuls' method
`duncan`	Duncan's method
`dunnett`	Dunnett's method

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Pairwise comparisons of means

Description

pwmean performs pairwise comparisons of means. It computes all pairwise differences of the means of *varname* over the combination of the levels of the variables in *varlist*. The tests and confidence intervals for the pairwise comparisons assume equal variances across groups. pwmean also allows for adjusting the confidence intervals and p-values to account for multiple comparisons using Bonferroni's method, Scheffé's method, Tukey's method, Dunnett's method, and others.

See [R] **pwcompare** for performing pairwise comparisons of means, estimated marginal means, and other types of marginal linear predictions after anova, regress, and most other estimation commands.

See [R] **margins, pwcompare** for performing pairwise comparisons of marginal probabilities and other linear and nonlinear predictions after estimation commands.

Options

Main

over(*varlist*) is required and specifies that means are computed for each combination of the levels of the variables in *varlist*.

mcompare(*method*) specifies the method for computing p-values and confidence intervals that account for multiple comparisons.

Most methods adjust the comparisonwise error rate, α_c, to achieve a prespecified experimentwise error rate, α_e.

mcompare(noadjust) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m\alpha_c$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

mcompare(sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where m is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the m comparisons are independent.

mcompare(scheffe) controls the experimentwise error rate using the F (or χ^2) distribution with degrees of freedom equal to $k - 1$ where k is the number of means being compared.

mcompare(tukey) uses what is commonly referred to as Tukey's honestly significant difference. This method uses the Studentized range distribution instead of the t distribution.

`mcompare(snk)` is a variation on `mcompare(tukey)` that counts only the number of means participating in the range for a given comparison instead of the full number of means.

`mcompare(duncan)` is a variation on `mcompare(snk)` with additional adjustment to the significance probabilities.

`mcompare(dunnett)` uses Dunnett's method for making comparisons with a reference category.

Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**. The significance level used by the `groups` option is $100 - \#$, expressed as a percentage.

`cieffects` specifies that a table of the pairwise comparisons of means with their standard errors and confidence intervals be reported. This is the default.

`pveffects` specifies that a table of the pairwise comparisons of means with their standard errors, test statistics, and p-values be reported.

`effects` specifies that a table of the pairwise comparisons of means with their standard errors, test statistics, p-values, and confidence intervals be reported.

`cimeans` specifies that a table of the means with their standard errors and confidence intervals be reported.

`groups` specifies that a table of the means with their standard errors and group codes be reported. Means with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted by the mean or difference that is displayed in the table.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`.

`cformat(%`*fmt*`)` specifies how to format means, standard errors, and confidence limits in the table of pairwise comparison of means.

`pformat(%`*fmt*`)` specifies how to format p-values in the table of pairwise comparison of means.

`sformat(%`*fmt*`)` specifies how to format test statistics in the table of pairwise comparison of means.

`nolstretch` specifies that the width of the table of estimated comparisons not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of estimated comparisons up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

Remarks

`pwmean` performs pairwise comparisons (differences) of means, assuming a common variance among groups. It can easily adjust the p-values and confidence intervals for the differences to account for the elevated type I error rate due to multiple comparisons. Adjustments for multiple comparisons can be made using Bonferroni's method, Scheffé's method, Tukey's method, Dunnett's method, and others.

Remarks are presented under the following headings:

Group means
Pairwise differences of means
Group output
Adjusting for multiple comparisons
Tukey's method
Dunnett's method
Multiple over() variables
Equal variance assumption

Group means

Suppose we have data on the wheat yield of fields that were each randomly assigned an application of one of five types of fertilizers. Let's first look at the mean yield for each type of fertilizer.

```
. use http://www.stata-press.com/data/r12/yield
(Artificial wheat yield dataset)
. pwmean yield, over(fertilizer) cimeans
Pairwise comparisons of means with equal variances
over         : fertilizer
```

			Unadjusted	
yield	Mean	Std. Err.	[95% Conf.	Interval]
fertilizer				
1	41.36243	1.124298	39.14509	43.57977
2	44.98515	1.124298	42.7678	47.20249
3	41.85306	1.124298	39.63571	44.0704
4	46.28523	1.124298	44.06789	48.50258
5	40.1241	1.124298	37.90676	42.34145

Pairwise differences of means

We can compute all pairwise differences in mean wheat yields for the types of fertilizers.

```
. pwmean yield, over(fertilizer) effects
Pairwise comparisons of means with equal variances
over         : fertilizer
```

			Unadjusted		Unadjusted	
yield	Contrast	Std. Err.	t	P>|t|	[95% Conf.	Interval]
fertilizer						
2 vs 1	3.62272	1.589997	2.28	0.024	.4869212	6.758518
3 vs 1	.4906299	1.589997	0.31	0.758	-2.645169	3.626428
4 vs 1	4.922803	1.589997	3.10	0.002	1.787005	8.058602
5 vs 1	-1.238328	1.589997	-0.78	0.437	-4.374127	1.89747
3 vs 2	-3.13209	1.589997	-1.97	0.050	-6.267889	.0037086
4 vs 2	1.300083	1.589997	0.82	0.415	-1.835715	4.435882
5 vs 2	-4.861048	1.589997	-3.06	0.003	-7.996847	-1.725249
4 vs 3	4.432173	1.589997	2.79	0.006	1.296375	7.567972
5 vs 3	-1.728958	1.589997	-1.09	0.278	-4.864757	1.406841
5 vs 4	-6.161132	1.589997	-3.87	0.000	-9.29693	-3.025333

The contrast in the row labeled (2 vs 1) is the difference in the mean wheat yield for fertilizer 2 and fertilizer 1. At a 5% significance level, we conclude that there is a difference in the means for these two fertilizers. Likewise, the rows labeled (4 vs 1), (5 vs 2), (4 vs 3) and (5 vs 4) show differences in these pairs of means. In all, we find that 5 of the 10 mean differences are significantly different from zero at a 5% significance level.

We can specify the sort option to order the differences from smallest to largest in the table.

```
. pwmean yield, over(fertilizer) effects sort
Pairwise comparisons of means with equal variances
over          : fertilizer
```

2 vs 1	3.62272	1.589997	2.28	0.024	.4869212	6.758518
4 vs 3	4.432173	1.589997	2.79	0.006	1.296375	7.567972
4 vs 1	4.922803	1.589997	3.10	0.002	1.787005	8.058602

Ordering the pairwise differences is particularly convenient when we are comparing means for a large number of groups.

Group output

We can use the group option to see the mean of each group and a visual representation of the tests for differences.

```
. pwmean yield, over(fertilizer) group sort
Pairwise comparisons of means with equal variances
over          : fertilizer
```

			Unadjusted
yield	Mean	Std. Err.	Groups
fertilizer			
5	40.1241	1.124298	A
1	41.36243	1.124298	A
3	41.85306	1.124298	AB
2	44.98515	1.124298	BC
4	46.28523	1.124298	C

```
Note: Means sharing a letter in the group label
      are not significantly different at the 5%
      level.
```

Fertilizers 5, 1, and 3 are all in group A. This means that at our 5% level of significance, we have insufficient information to distinguish their means. Likewise, fertilizers 3 and 2 are in group B and cannot be distinguished at the 5% level. The same is true for fertilizers 2 and 4 in group C.

Fertilizer 5 and fertilizer 2 have no letters in common, indicating that the mean yields of these two groups are significantly different at the 5% level. We can conclude that any other fertilizers without a letter in common have significantly different means as well.

Adjusting for multiple comparisons

The statistics in the examples above take no account that we are performing 10 comparisons. With our 5% significance level and assuming the comparisons are independent, we expect 1 in 20 tests of comparisons to be significant, even if all the population means are truly the same. If we are performing many comparisons, then we should account for the fact that some tests will be found significant by chance alone. More formally, the test for each pairwise comparison is made without adjusting for the elevated type I experimentwise error rate that is introduced when performing multiple tests. We can use the `mcompare()` option to adjust the confidence intervals and p-values for multiple comparisons.

Tukey's method

Of the available adjustments for multiple comparisons, Tukey's honestly significant difference, Student–Newman–Keuls' method, and Duncan's method are most often used when performing all pairwise comparisons of means. Of these, Tukey's method is the most conservative and Duncan's method is the least conservative. For further discussion of each of the multiple-comparison adjustments, see [R] **pwcompare**.

Here we use Tukey's adjustment to compute p-values and confidence intervals for the pairwise differences.

```
. pwmean yield, over(fertilizer) effects sort mcompare(tukey)
Pairwise comparisons of means with equal variances
over          : fertilizer
```

	Number of Comparisons
fertilizer	10

yield	Contrast	Std. Err.	Tukey t	Tukey P>|t|	Tukey [95% Conf.	Interval]
fertilizer						
5 vs 4	-6.161132	1.589997	-3.87	0.001	-10.53914	-1.78312
5 vs 2	-4.861048	1.589997	-3.06	0.021	-9.239059	-.4830368
3 vs 2	-3.13209	1.589997	-1.97	0.285	-7.510101	1.245921
5 vs 3	-1.728958	1.589997	-1.09	0.813	-6.106969	2.649053
5 vs 1	-1.238328	1.589997	-0.78	0.936	-5.616339	3.139683
3 vs 1	.4906299	1.589997	0.31	0.998	-3.887381	4.868641
4 vs 2	1.300083	1.589997	0.82	0.925	-3.077928	5.678095
2 vs 1	3.62272	1.589997	2.28	0.156	-.7552913	8.000731
4 vs 3	4.432173	1.589997	2.79	0.046	.0541623	8.810185
4 vs 1	4.922803	1.589997	3.10	0.019	.5447922	9.300815

When using a 5% significance level, Tukey's adjustment indicates that four pairs of means are different. With the adjustment, we no longer conclude that the difference in the mean yields for fertilizers 2 and 1 is significantly different from zero.

Dunnett's method

Now let's suppose that fertilizer 1 actually represents fields on which no fertilizer was applied. In this case, we can use Dunnett's method for comparing each of the fertilizers to the control.

```
. pwmean yield, over(fertilizer) effects mcompare(dunnett)
Pairwise comparisons of means with equal variances
over         : fertilizer
```

	Number of Comparisons
fertilizer	4

yield	Contrast	Std. Err.	Dunnett t	Dunnett P>|t|	Dunnett [95% Conf.	Interval]
fertilizer						
2 vs 1	3.62272	1.589997	2.28	0.079	-.2918331	7.537273
3 vs 1	.4906299	1.589997	0.31	0.994	-3.423923	4.405183
4 vs 1	4.922803	1.589997	3.10	0.008	1.00825	8.837356
5 vs 1	-1.238328	1.589997	-0.78	0.852	-5.152881	2.676225

Using Dunnett's adjustment, we conclude that only fertilizer 4 produces a mean yield that is significantly different from the mean yield of the field with no fertilizer applied.

By default, `pwmean` treats the lowest level of the group variable as the control. If, for instance, fertilizer 3 was our control group, we could type

```
. pwmean yield, over(b3.fertilizer) effects mcompare(dunnett)
```

using the `b3.` factor-variable operator to specify this level as the reference level.

Multiple over() variables

When we specify more than one variable in the `over()` option, pairwise comparisons are performed for the means defined by each combination of levels of these variables.

```
. pwmean yield, over(fertilizer irrigation) group
Pairwise comparisons of means with equal variances
over         : fertilizer irrigation
```

yield	Mean	Std. Err.	Unadjusted Groups
fertilizer#irrigation			
1 0	36.91257	1.116571	A
1 1	45.81229	1.116571	B
2 0	38.79482	1.116571	A C
2 1	51.17547	1.116571	E
3 0	36.34383	1.116571	A
3 1	47.36229	1.116571	B
4 0	41.81757	1.116571	CD
4 1	50.7529	1.116571	E
5 0	35.69507	1.116571	A
5 1	44.55313	1.116571	B D

```
Note: Means sharing a letter in the group label are not
      significantly different at the 5% level.
```

Here the row labeled `1 0` is the mean for the fields treated with fertilizer 1 and without irrigation. This mean is significantly different from the mean of all fertilizer/irrigation pairings that do not have an A in the "Unadjusted Groups" column. These include all pairings where the fields were irrigated as well as the fields treated with fertilizer 4 but without irrigation.

Equal variance assumption

`pwmean` performs multiple comparisons assuming that there is a common variance for all groups. In the case of two groups, this is equivalent to performing the familiar two-sample t test when equal variances are assumed.

```
. ttest yield, by(irrigation)
Two-sample t test with equal variances
```

Group	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf.	Interval]
0	100	37.91277	.5300607	5.300607	36.86102	38.96453
1	100	47.93122	.5630353	5.630353	46.81403	49.0484
combined	200	42.92199	.5242462	7.413961	41.8882	43.95579
diff		-10.01844	.7732872		-11.54338	-8.493509

```
    diff = mean(0) - mean(1)                                      t = -12.9557
Ho: diff = 0                     degrees of freedom =      198

    Ha: diff < 0                 Ha: diff != 0                 Ha: diff > 0
 Pr(T < t) = 0.0000         Pr(|T| > |t|) = 0.0000          Pr(T > t) = 1.0000
```

```
. pwmean yield, over(irrigation) effects
Pairwise comparisons of means with equal variances
over          : irrigation
```

yield	Contrast	Std. Err.	Unadjusted t	Unadjusted P>|t|	Unadjusted [95% Conf.	Interval]
irrigation						
1 vs 0	10.01844	.7732872	12.96	0.000	8.493509	11.54338

The signs for the difference, the test statistic, and the confidence intervals are reversed because the difference is taken in the opposite direction. The p-value from `pwmean` is equivalent to the one for the two-sided test in the `ttest` output.

`pwmean` extends the capabilities of `ttest` to allow for simultaneously comparing all pairs of means and to allow for using one common variance estimate for all the tests instead of computing a separate pooled variance for each pair of means when using multiple `ttest` commands. In addition, `pwmean` allows adjustments for multiple comparisons, many of which rely on an assumption of equal variances among groups.

Saved results

`pwmean` saves the following in `e()`:

Scalars

`e(df_r)`	variance degrees of freedom
`e(balanced)`	`1` if fully balanced data; `0` otherwise

Macros

`e(cmd)`	`pwmean`
`e(cmdline)`	command as typed
`e(title)`	title in output
`e(depvar)`	name of variable from which the means are computed
`e(over)`	*varlist* from `over()`
`e(properties)`	`b V`

Matrices

`e(b)`	mean estimates
`e(V)`	variance–covariance matrix of the mean estimates
`e(error)`	mean estimability codes; `0` means estimable, `8` means not estimable
`e(b_vs)`	mean difference estimates
`e(V_vs)`	variance–covariance matrix of the mean difference estimates
`e(error_vs)`	mean difference estimability codes; `0` means estimable, `8` means not estimable
`e(k_groups)`	number of significance groups for each term

Methods and formulas

`pwmean` is implemented as an ado-file.

`pwmean` is a convenience command that uses `pwcompare` after fitting a fully factorial linear model. See *Methods and formulas* described in [R] **pwcompare**.

Title

pwmean postestimation — Postestimation tools for pwmean

Description

The following postestimation commands are available after `pwmean`:

Command	Description
`estat`	VCE; `estat vce` only
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

Remarks

In *Pairwise differences of means* of [R] **pwmean**, we computed all pairwise differences in mean wheat yields for five fertilizers.

```
. use http://www.stata-press.com/data/r12/yield
(Artificial wheat yield dataset)
. pwmean yield, over(fertilizer)
Pairwise comparisons of means with equal variances
over         : fertilizer
```

yield	Contrast	Std. Err.	Unadjusted [95% Conf.	Interval]
fertilizer				
2 vs 1	3.62272	1.589997	.4869212	6.758518
3 vs 1	.4906299	1.589997	-2.645169	3.626428
4 vs 1	4.922803	1.589997	1.787005	8.058602
5 vs 1	-1.238328	1.589997	-4.374127	1.89747
3 vs 2	-3.13209	1.589997	-6.267889	.0037086
4 vs 2	1.300083	1.589997	-1.835715	4.435882
5 vs 2	-4.861048	1.589997	-7.996847	-1.725249
4 vs 3	4.432173	1.589997	1.296375	7.567972
5 vs 3	-1.728958	1.589997	-4.864757	1.406841
5 vs 4	-6.161132	1.589997	-9.29693	-3.025333

After `pwmean`, we can use `testnl` to test whether the improvement in mean wheat yield when using fertilizer 4 instead of fertilizer 5 is significantly different from 10%.

```
. testnl (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1
  (1)  (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1
             F(1, 195) =        1.57
              Prob > F =        0.2121
```

The improvement is not significantly different from 10%.

Title

qc — Quality control charts

Syntax

Draw a c chart

`cchart` *defect_var unit_var* [, *cchart_options*]

Draw a p (fraction-defective) chart

`pchart` *reject_var unit_var ssize_var* [, *pchart_options*]

Draw an R (range or dispersion) chart

`rchart` *varlist* [*if*] [*in*] [, *rchart_options*]

Draw an $\overline{\text{X}}$ *(control line) chart*

`xchart` *varlist* [*if*] [*in*] [, *xchart_options*]

Draw vertically aligned $\overline{\text{X}}$ *and R charts*

`shewhart` *varlist* [*if*] [*in*] [, *shewhart_options*]

cchart_options	Description
Main	
`nograph`	suppress graph
Plot	
connect_options	affect rendition of the plotted points
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Control limits	
`clopts(`*cline_options*`)`	affect rendition of the control limits
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

pchart_options	Description
Main	
`stabilized`	stabilize the p chart when sample sizes are unequal
`nograph`	suppress graph
`generate(`*newvar*$_f$ *newvar*$_{\rm lcl}$ *newvar*$_{\rm ucl}$`)`	store the fractions of defective elements and the lower and upper control limits
Plot	
connect_options	affect rendition of the plotted points
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Control limits	
`clopts(`*cline_options*`)`	affect rendition of the control limits
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

rchart_options	Description
Main	
`std(#)`	user-specified standard deviation
`nograph`	suppress graph
Plot	
connect_options	affect rendition of the plotted points
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Control limits	
`clopts(`*cline_options*`)`	affect rendition of the control limits
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

xchart_options	Description
Main	
`std(#)`	user-specified standard deviation
`mean(#)`	user-specified mean
`lower(#) upper(#)`	lower and upper limits of the X-bar limits
`nograph`	suppress graph
Plot	
connect_options	affect rendition of the plotted points
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Control limits	
`clopts(`*cline_options*`)`	affect rendition of the control limits
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

shewhart_options	Description
Main	
`std(#)`	user-specified standard deviation
`mean(#)`	user-specified mean
`nograph`	suppress graph
Plot	
connect_options	affect rendition of the plotted points
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Control limits	
`clopts(`*cline_options*`)`	affect rendition of the control limits

rchart

Statistics > Other > Quality control > R chart

xchart

Statistics > Other > Quality control > X-bar chart

shewhart

Statistics > Other > Quality control > Vertically aligned X-bar and R chart

Description

These commands provide standard quality-control charts. `cchart` draws a c chart; `pchart`, a p (fraction-defective) chart; `rchart`, an R (range or dispersion) chart; `xchart`, an $\overline{X}$ (control line) chart; and `shewhart`, vertically aligned $\overline{X}$ and R charts.

Options

Main

`stabilized` stabilizes the p chart when sample sizes are unequal.

`std(#)` specifies the standard deviation of the process. The R chart is calculated (based on the range) if this option is not specified.

`mean(#)` specifies the grand mean, which is calculated if not specified.

`lower(#)` and `upper(#)` must be specified together or not at all. They specify the lower and upper limits of the $\overline{X}$ chart. Calculations based on the mean and standard deviation (whether specified by option or calculated) are used otherwise.

`nograph` suppresses the graph.

`generate(`*newvar*$_f$ *newvar*$_{\rm lcl}$ *newvar*$_{\rm ucl}$`)` stores the plotted values in the p chart. *newvar*$_f$ will contain the fractions of defective elements; *newvar*$_{\rm lcl}$ and *newvar*$_{\rm ucl}$ will contain the lower and upper control limits, respectively.

Plot

connect_options affect whether lines connect the plotted points and the rendition of those lines; see [G-3] ***connect_options***.

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Control limits

`clopts(`*cline_options*`)` affects the rendition of the control limits; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

combine_options (`shewhart` only) are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Control charts may be used to define the goal of a repetitive process, to control that process, and to determine if the goal has been achieved. Walter A. Shewhart of Bell Telephone Laboratories devised the first control chart in 1924. In 1931, Shewhart published *Economic Control of Quality of Manufactured Product*. According to Burr, "Few fields of knowledge have ever been so completely explored and charted in the first exposition" (1976, 29). Shewhart states that "a phenomenon will be said to be controlled when, through the use of past experience, we can predict, at least within limits, how the phenomenon may be expected to vary in the future. Here it is understood that prediction within limits means that we can state, at least approximately, the probability that the observed phenomenon will fall within given limits" (1931, 6).

For more information on quality-control charts, see Burr (1976), Duncan (1986), Harris (1999), or Ryan (2000).

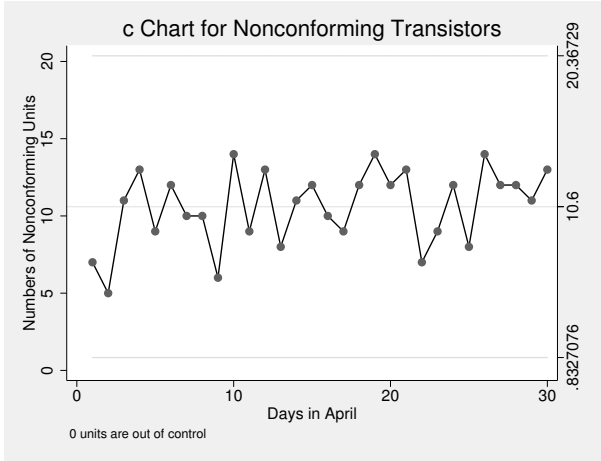
▷ Example 1: cchart

`cchart` graphs a c chart showing the number of nonconformities in a unit, where *defect_var* records the number of defects in each inspection unit and *unit_var* records the unit number. The unit numbers need not be in order. For instance, consider the following example dataset from Ryan (2000, 156):

```
. use http://www.stata-press.com/data/r12/ncu
. describe
Contains data from http://www.stata-press.com/data/r12/ncu.dta
  obs:            30
 vars:             2                          31 Mar 2011 03:56
 size:           240
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
day             float  %9.0g                  Days in April
defects         float  %9.0g                  Numbers of Nonconforming Units
-------------------------------------------------------------------------------
Sorted by:
. list in 1/5
```

	day	defects
1.	1	7
2.	2	5
3.	3	11
4.	4	13
5.	5	9

```
. cchart defects day, title(c Chart for Nonconforming Transistors)
```



The expected number of defects is 10.6, with lower and upper control limits of 0.8327 and 20.37, respectively. No units are out of control.

◁

▷ Example 2: pchart

`pchart` graphs a p chart, which shows the fraction of nonconforming items in a subgroup, where *reject_var* records the number rejected in each inspection unit, *unit_var* records the inspection unit number, and *ssize_var* records the number inspected in each unit.

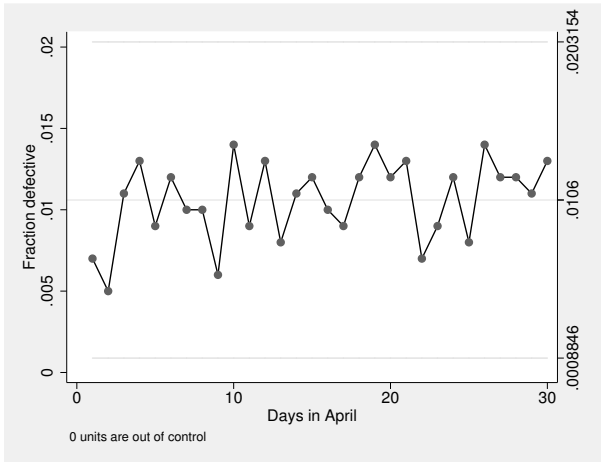
Consider the example dataset from Ryan (2000, 156) of the number of nonconforming transistors out of 1,000 inspected each day during the month of April:

```
. use http://www.stata-press.com/data/r12/ncu2
. describe
Contains data from http://www.stata-press.com/data/r12/ncu2.dta
  obs:            30
 vars:             3                          31 Mar 2011 14:13
 size:           360
-------------------------------------------------------------------------------
              storage  display     value
variable name   type   format      label      variable label
-------------------------------------------------------------------------------
day             float  %9.0g                  Days in April
rejects         float  %9.0g                  Numbers of Nonconforming Units
ssize           float  %9.0g                  Sample size
-------------------------------------------------------------------------------
Sorted by:
```

```
. list in 1/5
```

	day	rejects	ssize
1.	1	7	1000
2.	2	5	1000
3.	3	11	1000
4.	4	13	1000
5.	5	9	1000

```
. pchart rejects day ssize
```



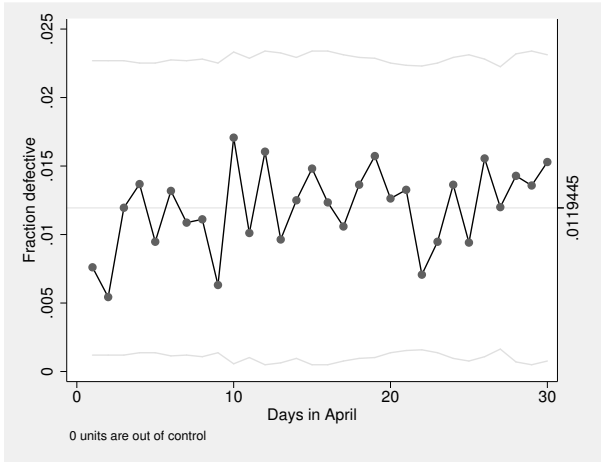
All the points are within the control limits, which are 0.0009 for the lower limit and 0.0203 for the upper limit.

Here the sample sizes are fixed at 1,000, so the `ssize` variable contains 1,000 for each observation. Sample sizes need not be fixed, however. Say that our data were slightly different:

```
. use http://www.stata-press.com/data/r12/ncu3
. list in 1/5
```

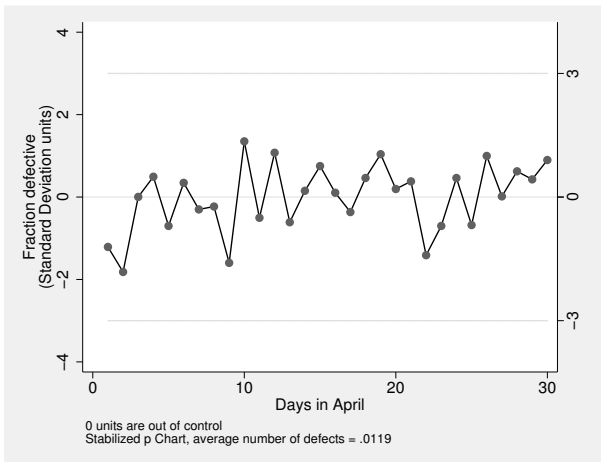
	day	rejects	ssize
1.	1	7	920
2.	2	5	920
3.	3	11	920
4.	4	13	950
5.	5	9	950

```
. pchart rejects day ssize
```



Here the control limits are, like the sample size, no longer constant. The `stabilize` option will stabilize the control chart:

```
. pchart rejects day ssize, stabilize
```



Example 3: rchart

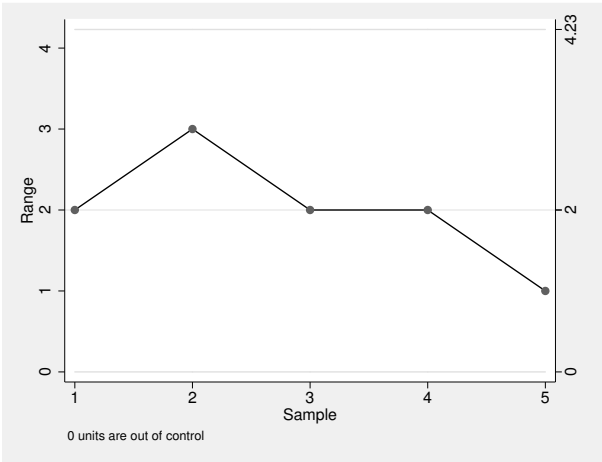
`rchart` displays an R chart showing the range for repeated measurements at various times. Variables within observations record measurements. Observations represent different samples.

For instance, say that we take five samples of 5 observations each. In our first sample, our measurements are 10, 11, 10, 11, and 12. The data are

```
. list
```

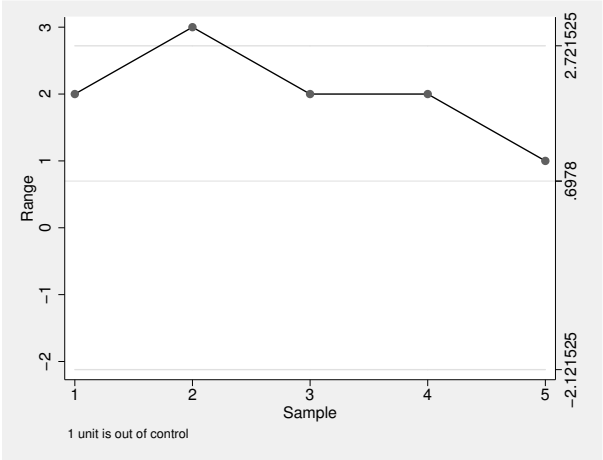
	m1	m2	m3	m4	m5
1.	10	11	10	11	12
2.	12	10	9	10	9
3.	10	11	10	12	10
4.	9	9	9	10	11
5.	12	12	12	12	13

```
. rchart m1-m5, connect(l)
```



The expected range in each sample is 2 with lower and upper control limits of 0 and 4.23, respectively. If we know that the process standard deviation is 0.3, we could specify

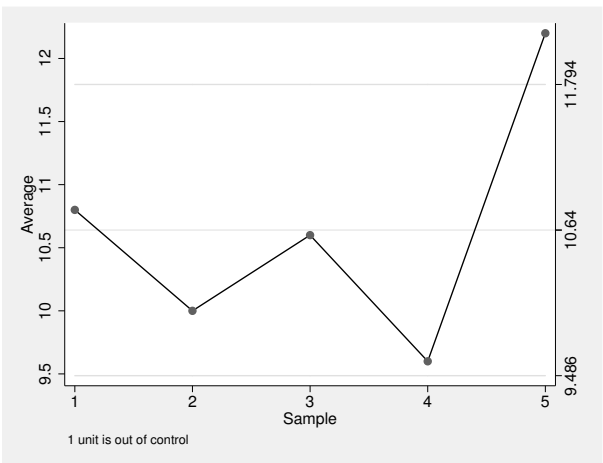
```
. rchart m1-m5, connect(l) std(.3)
```



Example 4: xchart

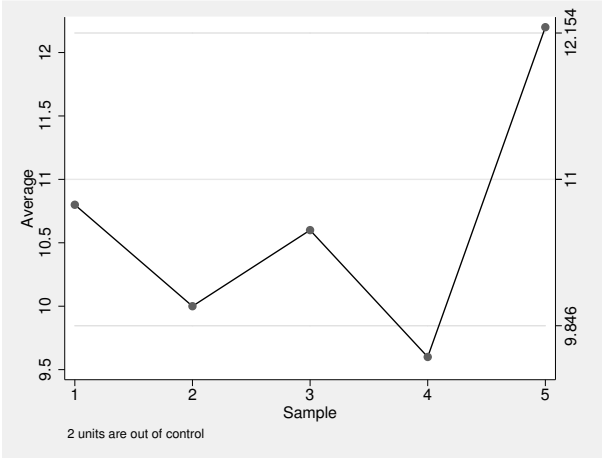
`xchart` graphs an $\overline{X}$ chart for repeated measurements at various times. Variables within observations record measurements, and observations represent different samples. Using the same data as in the previous example, we type

```
. xchart m1-m5, connect(l)
```



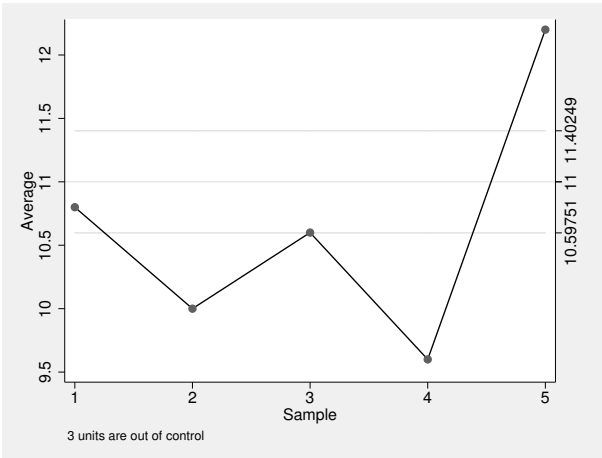
The average measurement in the sample is 10.64, and the lower and upper control limits are 9.486 and 11.794, respectively. Suppose that we knew from prior information that the mean of the process is 11. Then we would type

```
. xchart m1-m5, connect(l) mean(11)
```



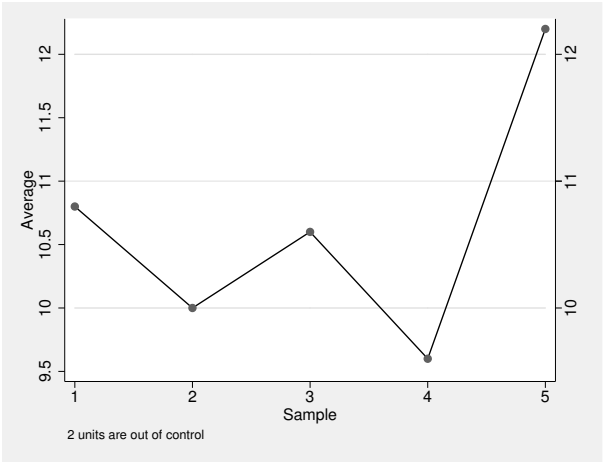
If we also know that the standard deviation of the process is 0.3, we could type

```
. xchart m1-m5, connect(l) mean(11) std(.3)
```



Finally, `xchart` allows us to specify our own control limits:

```
. xchart m1-m5, connect(l) mean(11) lower(10) upper(12)
```



◁

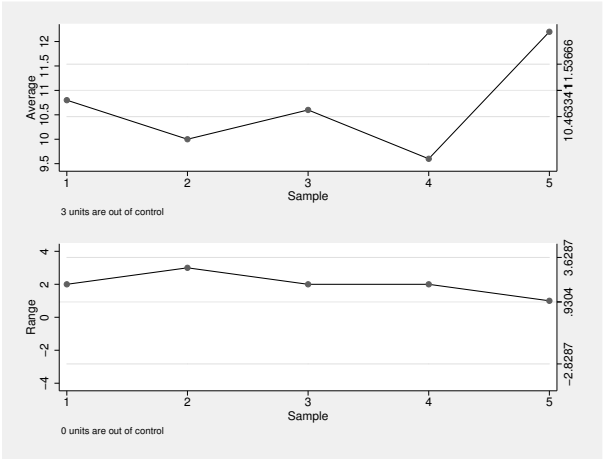
Walter Andrew Shewhart (1891–1967) was born in Illinois and educated as a physicist, with degrees from the Universities of Illinois and California. After a brief period teaching physics, he worked for the Western Electric Company and (from 1925) the Bell Telephone Laboratories. His name is most associated with control charts used in quality controls, but his many other interests ranged generally from quality assurance to the philosophy of science.

▷ Example 5: shewhart

`shewhart` displays a vertically aligned $\overline{X}$ and R chart in the same image. To produce the best-looking combined image possible, you will want to use the `xchart` and `rchart` commands separately and then combine the graphs. `shewhart`, however, is more convenient.

Using the same data as previously, but realizing that the standard deviation should have been 0.4, we type

```
. shewhart m1-m5, connect(l) mean(11) std(.4)
```



Saved results

`cchart` saves the following in `r()`:

Scalars

`r(cbar)`	expected number of nonconformities
`r(lcl_c)`	lower control limit
`r(ucl_c)`	upper control limit
`r(N)`	number of observations
`r(out_c)`	number of units out of control
`r(below_c)`	number of units below the lower limit
`r(above_c)`	number of units above the upper limit

`pchart` saves the following in `r()`:

Scalars

`r(pbar)`	average fraction of nonconformities
`r(lcl_p)`	lower control limit
`r(ucl_p)`	upper control limit
`r(N)`	number of observations
`r(out_p)`	number of units out of control
`r(below_p)`	number of units below the lower limit
`r(above_p)`	number of units above the upper limit

`rchart` saves the following in `r()`:

Scalars

`r(central_line)`	ordinate of the central line
`r(lcl_r)`	lower control limit
`r(ucl_r)`	upper control limit
`r(N)`	number of observations
`r(out_r)`	number of units out of control
`r(below_r)`	number of units below the lower limit
`r(above_r)`	number of units above the upper limit

`xchart` saves the following in `r()`:

Scalars

`r(xbar)`	grand mean
`r(lcl_x)`	lower control limit
`r(ucl_x)`	upper control limit
`r(N)`	number of observations
`r(out_x)`	number of units out of control
`r(below_x)`	number of units below the lower limit

`shewhart` saves in `r()` the combination of saved results from `xchart` and `rchart`.

Methods and formulas

`cchart`, `pchart`, `rchart`, `xchart`, and `shewhart` are implemented as ado-files.

For the c chart, the number of defects per unit, C, is taken to be a value of a random variable having a Poisson distribution. If k is the number of units available for estimating λ, the parameter of the Poisson distribution, and if C_i is the number of defects in the ith unit, then λ is estimated by $\overline{C} = \sum_i C_i/k$. Then

$$\begin{aligned}\text{central line} &= \overline{C}\\ \text{UCL} &= \overline{C} + 3\sqrt{\overline{C}}\\ \text{LCL} &= \overline{C} - 3\sqrt{\overline{C}}\end{aligned}$$

Control limits for the p chart are based on the sampling theory for proportions, using the normal approximation to the binomial. If k samples are taken, the estimator of p is given by $\overline{p} = \sum_i \widehat{p}_i/k$, where $\widehat{p}_i = x_i/n_i$, and x_i is the number of defects in the ith sample of size n_i. The central line and the control limits are given by

$$\begin{aligned}\text{central line} &= \overline{p}\\ \text{UCL} &= \overline{p} + 3\sqrt{\overline{p}(1-\overline{p})/n_i}\\ \text{LCL} &= \overline{p} - 3\sqrt{\overline{p}(1-\overline{p})/n_i}\end{aligned}$$

Control limits for the R chart are based on the distribution of the range of samples of size n from a normal population. If the standard deviation of the process, σ, is known,

$$\begin{aligned}\text{central line} &= d_2\sigma\\ \text{UCL} &= D_2\sigma\\ \text{LCL} &= D_1\sigma\end{aligned}$$

where d_2, D_1, and D_2 are functions of the number of observations in the sample and are obtained from the table published in Beyer (1976).

When σ is unknown,

$$\begin{aligned}\text{central line} &= \overline{R}\\ \text{UCL} &= (D_2/d_2)\overline{R}\\ \text{LCL} &= (D_1/d_2)\overline{R}\end{aligned}$$

where $\overline{R} = \sum_i R_i/k$ is the range of the k sample ranges R_i.

Control limits for the $\overline{\mathrm{X}}$ chart are given by

$$\begin{aligned}\text{central line} &= \overline{x}\\ \text{UCL} &= \overline{x} + (3/\sqrt{n})\sigma\\ \text{LCL} &= \overline{x} - (3/\sqrt{n})\sigma\end{aligned}$$

if σ is known. If σ is unknown,

$$\begin{aligned}\text{central line} &= \overline{x}\\ \text{UCL} &= \overline{x} + A_2\overline{R}\\ \text{LCL} &= \overline{x} - A_2\overline{R}\end{aligned}$$

where $\overline{R}$ is the average range as defined above and A_2 is a function (op. cit.) of the number of observations in the sample.

Title

qreg — Quantile regression

The documentation for [R] **qreg** has been updated. To see the latest PDF of [R] **qreg**, click here.

Syntax

Quantile regression

`qreg` *depvar* [*indepvars*] [*if*] [*in*] [*weight*] [, *qreg_options*]

Interquantile range regression

`iqreg` *depvar* [*indepvars*] [*if*] [*in*] [, *iqreg_options*]

Simultaneous-quantile regression

`sqreg` *depvar* [*indepvars*] [*if*] [*in*] [, *sqreg_options*]

Bootstrapped quantile regression

`bsqreg` *depvar* [*indepvars*] [*if*] [*in*] [, *bsqreg_options*]

Internal estimation command for quantile regression

`_qreg` [*depvar* [*indepvars*] [*if*] [*in*] [*weight*]] [, *_qreg_options*]

qreg_options	Description
Model	
`quantile(#)`	estimate # quantile; default is `quantile(.5)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats and line width
Optimization	
optimization_options	control the optimization process; seldom used
`wlsiter(#)`	attempt # weighted least-squares iterations before doing linear programming iterations

iqreg_options	Description
Model	
`quantiles(# #)`	interquantile range; default is `quantiles(.25 .75)`
`reps(#)`	perform # bootstrap replications; default is `reps(20)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`nodots`	suppress display of the replication dots
display_options	control column formats and line width

sqreg_options	Description
Model	
`quantiles(#` [`#` [`# ...`]]`)`	estimate # quantiles; default is `quantiles(.5)`
`reps(#)`	perform # bootstrap replications; default is `reps(20)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`nodots`	suppress display of the replication dots
display_options	control column formats and line width

bsqreg_options	Description
Model	
`quantile(#)`	estimate # quantile; default is `quantile(.5)`
`reps(#)`	perform # bootstrap replications; default is `reps(20)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
display_options	control column formats and line width

_qreg_options	Description
`quantile(#)`	estimate # quantile; default is `quantile(.5)`
`level(#)`	set confidence level; default is `level(95)`
`accuracy(#)`	relative accuracy required for linear programming algorithm; should not be specified
optimization_options	control the optimization process; seldom used

`by`, `mi estimate`, `rolling`, `statsby`, and `xi` are allowed by `qreg`, `iqreg`, `sqreg`, and `bsqreg`; `fracpoly`, `mfp`, `nestreg`, and `stepwise` are allowed only with `qreg`; see [U] **11.1.10 Prefix commands**.
`qreg` and `_qreg` allow `aweights` and `fweights`; see [U] **11.1.6 weight**.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

bsqreg

Statistics > Nonparametric analysis > Bootstrapped quantile regression

Description

qreg fits quantile (including median) regression models, also known as least–absolute-value models (LAV or MAD) and minimum L1-norm models.

iqreg estimates interquantile range regressions, regressions of the difference in quantiles. The estimated variance–covariance matrix of the estimators (VCE) is obtained via bootstrapping.

sqreg estimates simultaneous-quantile regression. It produces the same coefficients as qreg for each quantile. Reported standard errors will be similar, but sqreg obtains an estimate of the VCE via bootstrapping, and the VCE includes between-quantile blocks. Thus you can test and construct confidence intervals comparing coefficients describing different quantiles.

bsqreg is equivalent to sqreg with one quantile.

_qreg is the internal estimation command for quantile regression. _qreg is not intended to be used directly; see *Methods and formulas* below.

Options for qreg

Model

quantile(#) specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

Reporting

level(#); see [R] **estimation options**.

display_options: cformat(%*fmt*), pformat(%*fmt*), sformat(%*fmt*), and nolstretch; see [R] **estimation options**.

Optimization

optimization_options: iterate(#), [no]log, trace. iterate() specifies the maximum number of iterations; log/nolog specifies whether to show the iteration log; and trace specifies that the iteration log should include the current parameter vector. These options are seldom used.

wlsiter(#) specifies the number of weighted least-squares iterations that will be attempted before the linear programming iterations are started. The default value is 1. If there are convergence problems, increasing this number should help.

Options for iqreg

Model

quantiles(# #) specifies the quantiles to be compared. The first number must be less than the second, and both should be between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. Not specifying this option is equivalent to specifying quantiles(.25 .75), meaning the interquartile range.

reps(#) specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). reps(20) is the default and is arguably too small. reps(100) would perform 100 bootstrap replications. reps(1000) would perform 1,000 replications.

Reporting

`level(#)`; see [R] **estimation options**.

`nodots` suppresses display of the replication dots.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Options for sqreg

Model

`quantiles(# [# [# ...]])` specifies the quantiles to be estimated and should contain numbers between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.

Reporting

`level(#)`; see [R] **estimation options**.

`nodots` suppresses display of the replication dots.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Options for bsqreg

Model

`quantile(#)` specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.

Reporting

`level(#)`; see [R] **estimation options**.

display_options: `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Options for _qreg

`quantile(#)` specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. The default value of 0.5 corresponds to the median.

`level(#)`; see [R] **estimation options**.

`accuracy(#)` should not be specified; it specifies the relative accuracy required for the linear programming algorithm. If the potential for improving the sum of weighted deviations by deleting an observation from the basis is less than this on a percentage basis, the algorithm will be said to have converged. The default value is 10^{-10}.

optimization_options: `iterate(#)`, [`no`]`log`, `trace`. `iterate()` specifies the maximum number of iterations; `log`/`nolog` specifies whether to show the iteration log; and `trace` specifies that the iteration log should include the current parameter vector. These options are seldom used.

Remarks

Remarks are presented under the following headings:

Median regression
Generalized quantile regression
Estimated standard errors
Interquantile and simultaneous-quantile regression

Median regression

`qreg` without options fits quantile regression models. The most common form is median regression, where the object is to estimate the median of the dependent variable, conditional on the values of the independent variables. This method is similar to ordinary regression, where the objective is to estimate the mean of the dependent variable. Simply put, median regression finds a line through the data that minimizes the sum of the *absolute* residuals rather than the sum of the *squares* of the residuals, as in ordinary regression. Cameron and Trivedi (2010, chap. 7) provide a nice introduction to quantile regression using Stata.

▷ Example 1

Consider a two-group experimental design with 5 observations per group:

```
. use http://www.stata-press.com/data/r12/twogrp
. list
```

	x	y
1.	0	0
2.	0	1
3.	0	3
4.	0	4
5.	0	95
6.	1	14
7.	1	19
8.	1	20
9.	1	22
10.	1	23

```
. qreg y x
Iteration  1:  WLS sum of weighted deviations =  121.88268
Iteration  1: sum of abs. weighted deviations =       111
Iteration  2: sum of abs. weighted deviations =       110
Median regression                               Number of obs =        10
  Raw sum of deviations      157 (about 14)
  Min sum of deviations      110                Pseudo R2     =    0.2994
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
x	17	3.924233	4.33	0.003	7.950702	26.0493
_cons	3	2.774852	1.08	0.311	-3.39882	9.39882

We have estimated the equation

$$\mathrm{y}_{\mathrm{median}} = 3 + 17\,\mathrm{x}$$

We look back at our data. x takes on the values 0 and 1, so the median for the $\mathrm{x} = 0$ group is 3, whereas for $\mathrm{x} = 1$ it is $3 + 17 = 20$. The output reports that the raw sum of absolute deviations about 14 is 157; that is, the sum of $|\mathrm{y} - 14|$ is 157. Fourteen is the unconditional median of y, although in these data, any value between 14 and 19 could also be considered an unconditional median (we have an even number of observations, so the median is bracketed by those two values). In any case, the raw sum of deviations of y about the median would be the same no matter what number we choose between 14 and 19. (With a "median" of 14, the raw sum of deviations is 157. Now think of choosing a slightly larger number for the median and recalculating the sum. Half the observations will have larger negative residuals, but the other half will have smaller positive residuals, resulting in no net change.)

We turn now to the actual estimated equation. The sum of the absolute deviations about the solution $\mathrm{y}_{\mathrm{median}} = 3 + 17\mathrm{x}$ is 110. The pseudo-R^2 is calculated as $1 - 110/157 \approx 0.2994$. This result is based on the idea that the median regression is the maximum likelihood estimate for the double-exponential distribution.

◁

❑ Technical note

qreg is an alternative to regular regression or robust regression—see [R] **regress** and [R] **rreg**. Let's compare the results:

```
. regress y x
      Source |       SS       df       MS              Number of obs =      10
-------------+------------------------------           F(  1,     8) =    0.00
       Model |         2.5     1         2.5           Prob > F      =  0.9586
    Residual |      6978.4     8       872.3           R-squared     =  0.0004
-------------+------------------------------           Adj R-squared = -0.1246
       Total |      6980.9     9  775.655556           Root MSE      =  29.535
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
x	-1	18.6794	-0.05	0.959	-44.07477	42.07477
_cons	20.6	13.20833	1.56	0.157	-9.858465	51.05847

Unlike qreg, regress fits ordinary linear regression and is concerned with predicting the mean rather than the median, so both results are, in a technical sense, correct. Putting aside those technicalities, however, we tend to use either regression to describe the central tendency of the data, of which the mean is one measure and the median another. Thus we can ask, "which method better describes the central tendency of these data?"

Means—and therefore ordinary linear regression—are sensitive to outliers, and our data were purposely designed to contain two such outliers: 95 for `x` = 0 and 14 for `x` = 1. These two outliers dominated the ordinary regression and produced results that do not reflect the central tendency well—you are invited to enter the data and graph `y` against `x`.

Robust regression attempts to correct the outlier-sensitivity deficiency in ordinary regression:

```
. rreg y x, genwt(wt)
   Huber iteration 1:  maximum difference in weights = .7311828
   Huber iteration 2:  maximum difference in weights = .17695779
   Huber iteration 3:  maximum difference in weights = .03149585
Biweight iteration 4:  maximum difference in weights = .1979335
Biweight iteration 5:  maximum difference in weights = .23332905
Biweight iteration 6:  maximum difference in weights = .09960067
Biweight iteration 7:  maximum difference in weights = .02691458
Biweight iteration 8:  maximum difference in weights = .0009113
Robust regression                                     Number of obs =      10
                                                      F(  1,     8) =   80.63
                                                      Prob > F      =  0.0000
------------------------------------------------------------------------------
           y |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
           x |   18.16597   2.023114     8.98   0.000     13.50066    22.83128
       _cons |   2.000003   1.430558     1.40   0.200    -1.298869    5.298875
------------------------------------------------------------------------------
```

Here `rreg` discarded the first outlier completely. (We know this because we included the `genwt()` option on `rreg` and, after fitting the robust regression, examined the weights.) For the other "outlier", `rreg` produced a weight of 0.47.

In any case, the answers produced by `qreg` and `rreg` to describe the central tendency are similar, but the standard errors are different. In general, robust regression will have smaller standard errors because it is not as sensitive to the exact placement of observations near the median. Also, some authors (Rousseeuw and Leroy 1987, 11) have noted that quantile regression, unlike the median, may be sensitive to even one outlier, if its leverage is high enough. ❑

▷ Example 2

Let's now consider a less artificial example using the automobile data described in [U] **1.2.2 Example datasets**. Using median regression, we will regress each car's price on its weight and length and whether it is of foreign manufacture:

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. qreg price weight length foreign
Iteration  1:  WLS sum of weighted deviations =  112795.66
Iteration  1: sum of abs. weighted deviations =     111901
Iteration  2: sum of abs. weighted deviations =  110529.43
  (output omitted)
Iteration  8: sum of abs. weighted deviations =  108822.59
Median regression                               Number of obs =        74
  Raw sum of deviations   142205 (about 4934)
  Min sum of deviations 108822.6                Pseudo R2     =    0.2347
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	3.933588	.8602183	4.57	0.000	2.217937	5.649239
length	-41.25191	28.8693	-1.43	0.157	-98.82991	16.32609
foreign	3377.771	577.3391	5.85	0.000	2226.305	4529.237
_cons	344.6494	3260.244	0.11	0.916	-6157.702	6847.001

The estimated equation is

$$\texttt{price}_{\text{median}} = 3.93\,\texttt{weight} - 41.25\,\texttt{length} + 3377.8\,\texttt{foreign} + 344.65$$

The output may be interpreted in the same way as linear regression output; see [R] **regress**. The variables `weight` and `foreign` are significant, but `length` is not significant. The median price of the cars in these data is \$4,934. This value is a median (one of the two center observations), not *the* median, which would typically be defined as the midpoint of the two center observations.

◁

Generalized quantile regression

Generalized quantile regression is similar to median regression in that it estimates an equation describing a quantile other than the 0.5 (median) quantile. For example, specifying `quant(.25)` estimates the 25th percentile or the first quartile.

▷ Example 3

Again we will begin with the 10-observation artificial dataset we used at the beginning of *Median regression* above. We will estimate the 0.6667 quantile:

```
. use http://www.stata-press.com/data/r12/twogrp
. qreg y x, quant(0.6667)
Iteration  1:  WLS sum of weighted deviations =  152.32472
Iteration  1: sum of abs. weighted deviations =   138.0054
Iteration  2: sum of abs. weighted deviations =   136.6714
.6667 Quantile regression                       Number of obs =        10
  Raw sum of deviations 159.3334 (about 20)
  Min sum of deviations 136.6714                Pseudo R2     =    0.1422
```

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
x	18	54.21918	0.33	0.748	-107.0297	143.0297
_cons	4	38.33875	0.10	0.919	-84.40932	92.40932

The 0.6667 quantile in the data is 20. The estimated values are 4 for $x = 0$ and 22 for $x = 1$. These values are appropriate because the usual convention is to "count in" $(n + 1) \times$ quantile observations. ◁

▷ Example 4

Returning to real data, the equation for the 25th percentile of `price` based on `weight`, `length`, and `foreign` in our automobile data is

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)

. qreg price weight length foreign, quant(.25)
Iteration  1:  WLS sum of weighted deviations =  98938.466

Iteration  1: sum of abs. weighted deviations =  99457.766
Iteration  2: sum of abs. weighted deviations =  91339.779
  (output omitted)
Iteration 10: sum of abs. weighted deviations =  69603.554

.25 Quantile regression                             Number of obs =        74
  Raw sum of deviations  83825.5 (about 4187)
  Min sum of deviations 69603.55                    Pseudo R2     =    0.1697
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	1.831789	.668093	2.74	0.008	.4993194	3.164258
length	2.845558	24.78057	0.11	0.909	-46.57773	52.26885
foreign	2209.925	434.631	5.08	0.000	1343.081	3076.769
_cons	-1879.775	2808.067	-0.67	0.505	-7480.287	3720.737

Compared with our previous median regression, the coefficient on `length` now has a positive sign, and the coefficients on `foreign` and `weight` are reduced. The actual lower quantile is $4,187, substantially less than the median $4,934. It appears that the factors are weaker in this part of the distribution.

We can also estimate the upper quartile as a function of the same three variables:

```
. qreg price weight length foreign, quant(.75)
Iteration  1:  WLS sum of weighted deviations =  110931.48

Iteration  1: sum of abs. weighted deviations =  111305.91
Iteration  2: sum of abs. weighted deviations =  105989.57
  (output omitted)
Iteration  7: sum of abs. weighted deviations =  98395.935

.75 Quantile regression                             Number of obs =        74
  Raw sum of deviations 159721.5 (about 6342)
  Min sum of deviations 98395.94                    Pseudo R2     =    0.3840
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	9.22291	2.653579	3.48	0.001	3.930515	14.51531
length	-220.7833	80.13907	-2.76	0.007	-380.6156	-60.95096
foreign	3595.133	1727.704	2.08	0.041	149.3355	7040.931
_cons	20242.9	8534.529	2.37	0.020	3221.323	37264.49

This result tells a different story: `weight` is much more important, and `length` is now significant—with a negative coefficient! The prices of high-priced cars seem to be determined by factors different from those affecting the prices of low-priced cars.

◁

❑ Technical note

One explanation for having substantially different regression functions for different quantiles is that the data are heteroskedastic, as we will demonstrate below. The following statements create a sharply heteroskedastic set of data:

```
. drop _all
. set obs 10000
obs was 0, now 10000
. set seed 50550
. gen x = .1 + .9 * runiform()
. gen y = x * runiform()^2
```

Let's now fit the regressions for the 5th and 95th quantiles:

```
. qreg y x, quant(.05)
Iteration  1:  WLS sum of weighted deviations =  1080.7273

Iteration  1: sum of abs. weighted deviations =  1078.3192
Iteration  2: sum of abs. weighted deviations =  282.73545
  (output omitted)
Iteration  9: sum of abs. weighted deviations =  182.25244

.05 Quantile regression                              Number of obs =     10000
  Raw sum of deviations  182.357 (about .0009234)
  Min sum of deviations 182.2524                     Pseudo R2     =    0.0006

------------------------------------------------------------------------------
           y |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
           x |    .002601   .0002737     9.50   0.000     .0020646    .0031374
       _cons |  -.0001393   .0001666    -0.84   0.403     -.000466    .0001874
------------------------------------------------------------------------------

. qreg y x, quant(.95)
Iteration  1:  WLS sum of weighted deviations =  1237.5569

Iteration  1: sum of abs. weighted deviations =  1238.0014
Iteration  2: sum of abs. weighted deviations =  456.65044
  (output omitted)
Iteration  5: sum of abs. weighted deviations =   338.4389

.95 Quantile regression                              Number of obs =     10000
  Raw sum of deviations 554.6889 (about .61326343)
  Min sum of deviations 338.4389                     Pseudo R2     =    0.3899

------------------------------------------------------------------------------
           y |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
           x |   .8898259   .0060398   147.33   0.000     .8779867     .901665
       _cons |   .0021514   .0036623     0.59   0.557    -.0050275    .0093302
------------------------------------------------------------------------------
```

The coefficient on `x`, in particular, differs markedly between the two estimates. For the mathematically inclined, it is not too difficult to show that the theoretical lines are $y = 0.0025\,x$ for the 5th percentile and $y = 0.9025\,x$ for the 95th, numbers in close agreement with our numerical results.

❑

Estimated standard errors

qreg estimates the variance–covariance matrix of the coefficients by using a method of Koenker and Bassett (1982) and Rogers (1993). This approach is described in *Methods and formulas* below. Rogers (1992) reports that, although this method seems adequate for homoskedastic errors, it appears to understate the standard errors for heteroskedastic errors. The irony is that exploring heteroskedastic errors is one of the major benefits of quantile regression. Gould (1992, 1997b) introduced generalized versions of qreg that obtain estimates of the standard errors by using bootstrap resampling (see Efron and Tibshirani [1993] or Wu [1986] for an introduction to bootstrap standard errors). The iqreg, sqreg, and bsqreg commands provide a bootstrapped estimate of the entire variance–covariance matrix of the estimators.

▷ Example 5

The first example of qreg on real data above was a median regression of price on weight, length, and foreign using the automobile data. Here is the result of repeating the estimation using bootstrap standard errors:

```
. set seed 1001
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. bsqreg price weight length foreign
(fitting base model)
(bootstrapping .....................)
Median regression, bootstrap(20) SEs                Number of obs =        74
  Raw sum of deviations   142205 (about 4934)
  Min sum of deviations 108822.6                    Pseudo R2     =    0.2347
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	3.933588	3.12446	1.26	0.212	-2.297951	10.16513
length	-41.25191	83.71266	-0.49	0.624	-208.2116	125.7077
foreign	3377.771	1057.281	3.19	0.002	1269.09	5486.452
_cons	344.6494	7053.301	0.05	0.961	-13722.72	14412.01

The coefficient estimates are the same—indeed, they are obtained using the same technique. Only the standard errors differ. Therefore, the t statistics, significance levels, and confidence intervals also differ.

Because bsqreg (as well as sqreg and iqreg) obtains standard errors by randomly resampling the data, the standard errors it produces will not be the same from run to run, unless we first set the random-number seed to the same number; see [R] **set seed**.

By default, bsqreg, sqreg, and iqreg use 20 replications. We can control the number of replications by specifying the reps() option:

```
. bsqreg price weight length foreign, reps(1000)
(fitting base model)
(bootstrapping ..................(output omitted)...)
Median regression, bootstrap(1000) SEs                Number of obs =        74
  Raw sum of deviations   142205 (about 4934)
  Min sum of deviations 108822.6                      Pseudo R2     =    0.2347
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	3.933588	2.659381	1.48	0.144	-1.370379	9.237555
length	-41.25191	69.29771	-0.60	0.554	-179.4618	96.95802
foreign	3377.771	1094.947	3.08	0.003	1193.967	5561.575
_cons	344.6494	5916.906	0.06	0.954	-11456.25	12145.55

A comparison of the standard errors is informative:

Variable	qreg	bsqreg reps(20)	bsqreg reps(1000)
weight	.8602	3.124	2.670
length	28.87	83.71	69.65
foreign	577.3	1057.	1094.
_cons	3260.	7053.	5945.

The results shown above are typical for models with heteroskedastic errors. (Our dependent variable is price; if our model had been in terms of ln(price), the standard errors estimated by qreg and bsqreg would have been nearly identical.) Also, even for heteroskedastic errors, 20 replications is generally sufficient for hypothesis tests against 0. ◁

Interquantile and simultaneous-quantile regression

Consider a quantile-regression model where the qth quantile is given by

$$Q_q(y) = a_q + b_{q,1}x_1 + b_{q,2}x_2$$

For instance, the 75th and 25th quantiles are given by

$$Q_{0.75}(y) = a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2$$
$$Q_{0.25}(y) = a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2$$

The difference in the quantiles is then

$$Q_{0.75}(y) - Q_{0.25}(y) = (a_{0.75} - a_{0.25}) + (b_{0.75,1} - b_{0.25,1})x_1 + (b_{0.75,2} - b_{0.25,2})x_2$$

qreg fits models such as $Q_{0.75}(y)$ and $Q_{0.25}(y)$. iqreg fits interquantile models, such as $Q_{0.75}(y) - Q_{0.25}(y)$. The relationships of the coefficients estimated by qreg and iqreg are exactly as shown: iqreg reports coefficients that are the difference in coefficients of two qreg models, and, of course, iqreg reports the appropriate standard errors, which it obtains by bootstrapping.

sqreg is like qreg in that it estimates the equations for the quantiles

$$Q_{0.75}(y) = a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2$$
$$Q_{0.25}(y) = a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2$$

The coefficients it obtains are the same that would be obtained by estimating each equation separately using qreg. sqreg differs from qreg in that it estimates the equations simultaneously and obtains an estimate of the entire variance–covariance matrix of the estimators by bootstrapping. Thus you can perform hypothesis tests concerning coefficients both within and across equations.

For example, to fit the above model, you could type

```
. qreg y x1 x2, quantile(.25)
. qreg y x1 x2, quantile(.75)
```

Doing this, you would obtain estimates of the parameters, but you could not test whether $b_{0.25,1} = b_{0.75,1}$ or, equivalently, $b_{0.75,1} - b_{0.25,1} = 0$. If your interest really is in the difference of coefficients, you could type

```
. iqreg y x1 x2, quantiles(.25 .75)
```

The "coefficients" reported would be the difference in quantile coefficients. You could also estimate both quantiles simultaneously and then test the equality of the coefficients:

```
. sqreg y x1 x2, quantiles(.25 .75)
. test [q25]x1 = [q75]x1
```

Whether you use iqreg or sqreg makes no difference for this test. sqreg, however, because it estimates the quantiles simultaneously, allows you to test other hypotheses. iqreg, by focusing on quantile differences, presents results in a way that is easier to read.

Finally, sqreg can estimate quantiles singly,

```
. sqreg y x1 x2, quantiles(.5)
```

and can thereby be used as a substitute for the slower bsqreg. (Gould [1997b] presents timings demonstrating that sqreg is faster than bsqreg.) sqreg can also estimate more than two quantiles simultaneously:

```
. sqreg y x1 x2, quantiles(.25 .5 .75)
```

▷ Example 6

In demonstrating qreg, we performed quantile regressions using the automobile data. We discovered that the regression of price on weight, length, and foreign produced vastly different coefficients for the 0.25, 0.5, and 0.75 quantile regressions. Here are the coefficients that we obtained:

Variable	25th percentile	50th percentile	75th percentile
weight	1.83	3.93	9.22
length	2.85	−41.25	−220.8
foreign	2209.9	3377.8	3595.1
_cons	−1879.8	344.6	20242.9

All we can say, having estimated these equations separately, is that price seems to depend differently on the weight, length, and foreign variables depending on the portion of the price distribution we examine. We cannot be more precise because the estimates have been made separately. With sqreg, however, we can estimate all the effects simultaneously:

```
. sqreg price weight length foreign, q(.25 .5 .75) reps(100)
(fitting base model)
(bootstrapping .................  (output omitted) .....)
Simultaneous quantile regression                    Number of obs =        74
  bootstrap(100) SEs                                .25 Pseudo R2 =    0.1697
                                                    .50 Pseudo R2 =    0.2347
                                                    .75 Pseudo R2 =    0.3840
```

price	Coef.	Bootstrap Std. Err.	t	P>|t|	[95% Conf.	Interval]
q25						
weight	1.831789	1.244947	1.47	0.146	-.6511803	4.314758
length	2.845558	27.91648	0.10	0.919	-52.8321	58.52322
foreign	2209.925	911.6566	2.42	0.018	391.6836	4028.167
_cons	-1879.775	2756.871	-0.68	0.498	-7378.18	3618.63
q50						
weight	3.933588	2.732408	1.44	0.154	-1.516029	9.383205
length	-41.25191	75.8087	-0.54	0.588	-192.4476	109.9438
foreign	3377.771	921.578	3.67	0.000	1539.742	5215.8
_cons	344.6494	6810.32	0.05	0.960	-13238.1	13927.4
q75						
weight	9.22291	2.732795	3.37	0.001	3.772523	14.6733
length	-220.7833	87.38042	-2.53	0.014	-395.058	-46.50854
foreign	3595.133	1153.239	3.12	0.003	1295.07	5895.196
_cons	20242.9	9000.697	2.25	0.028	2291.579	38194.23

The coefficient estimates above are the same as those previously estimated, although the standard error estimates are a little different. `sqreg` obtains estimates of variance by bootstrapping. Rogers (1992) provides evidence that, for quantile regression, the bootstrap standard errors are better than those calculated analytically by Stata.

The important thing here, however, is that the full covariance matrix of the estimators has been estimated and stored, and thus it is now possible to perform hypothesis tests. Are the effects of `weight` the same at the 25th and 75th percentiles?

```
. test [q25]weight = [q75]weight
 ( 1)  [q25]weight - [q75]weight = 0
       F(  1,    70) =    8.29
            Prob > F =    0.0053
```

It appears that they are not. We can obtain a confidence interval for the difference by using `lincom`:

```
. lincom [q75]weight-[q25]weight
 ( 1)  - [q25]weight + [q75]weight = 0
```

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
(1)	7.391121	2.567684	2.88	0.005	2.270036	12.51221

Indeed, we could test whether the `weight` and `length` sets of coefficients are equal at the three quantiles estimated:

```
. quietly test [q25]weight = [q50]weight
. quietly test [q25]weight = [q75]weight, accum
```

```
. quietly test [q25]length = [q50]length, accum
. test [q25]length = [q75]length, accum
 ( 1)  [q25]weight - [q50]weight = 0
 ( 2)  [q25]weight - [q75]weight = 0
 ( 3)  [q25]length - [q50]length = 0
 ( 4)  [q25]length - [q75]length = 0
       F(  4,    70) =    2.21
            Prob > F =    0.0767
```

`iqreg` focuses on one quantile comparison but presents results that are more easily interpreted:

```
. set seed 1001
. iqreg price weight length foreign, q(.25 .75) reps(100) nodots
.75-.25 Interquantile regression                  Number of obs =        74
  bootstrap(100) SEs                              .75 Pseudo R2 =    0.3840
                                                  .25 Pseudo R2 =    0.1697
```

price	Coef.	Bootstrap Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	7.391121	2.467548	3.00	0.004	2.469752	12.31249
length	-223.6288	83.09868	-2.69	0.009	-389.3639	-57.89376
foreign	1385.208	1193.557	1.16	0.250	-995.2672	3765.683
_cons	22122.68	9009.159	2.46	0.017	4154.478	40090.88

Looking only at the 0.25 and 0.75 quantiles (the interquartile range), the `iqreg` command output is easily interpreted. Increases in `weight` correspond significantly to increases in `price` dispersion. Increases in `length` correspond to decreases in `price` dispersion. The `foreign` variable does not significantly change `price` dispersion.

Do not make too much of these results; the purpose of this example is simply to illustrate the `sqreg` and `iqreg` commands and to do so in a context that suggests why analyzing dispersion might be of interest.

`lincom` after `sqreg` produced the same t statistic for the interquartile range of `weight`, as did the `iqreg` command above. In general, they will not agree exactly because of the randomness of bootstrapping, unless the random-number seed is set to the same value before estimation (as was done here).

◁

Gould (1997a) presents simulation results showing that the coverage—the actual percentage of confidence intervals containing the true value—for `iqreg` is appropriate.

Saved results

qreg saves the following in e():

Scalars

e(N)	number of observations
e(df_m)	model degrees of freedom
e(df_r)	residual degrees of freedom
e(q)	quantile requested
e(q_v)	value of the quantile
e(sum_adev)	sum of absolute deviations
e(sum_rdev)	sum of raw deviations
e(f_r)	residual density estimate
e(rank)	rank of e(V)
e(convcode)	0 if converged; otherwise, return code for why nonconvergence

Macros

e(cmd)	qreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

iqreg saves the following in e():

Scalars

e(N)	number of observations
e(df_r)	residual degrees of freedom
e(q0)	lower quantile requested
e(q1)	upper quantile requested
e(reps)	number of replications
e(sumrdev0)	lower quantile sum of raw deviations
e(sumrdev1)	upper quantile sum of raw deviations
e(sumadev0)	lower quantile sum of absolute deviations
e(sumadev1)	upper quantile sum of absolute deviations
e(rank)	rank of e(V)
e(convcode)	0 if converged; otherwise, return code for why nonconvergence

Macros

e(cmd)	iqreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(vcetype)	title used to label Std. Err.
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

sqreg saves the following in e():

Scalars

e(N)	number of observations
e(df_r)	residual degrees of freedom
e(n_q)	number of quantiles requested
e(q#)	the quantiles requested
e(reps)	number of replications
e(sumrdv#)	sum of raw deviations for q#
e(sumadv#)	sum of absolute deviations for q#
e(rank)	rank of e(V)
e(convcode)	0 if converged; otherwise, return code for why nonconvergence

Macros

e(cmd)	sqreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(eqnames)	names of equations
e(vcetype)	title used to label Std. Err.
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

bsqreg saves the following in e():

Scalars

e(N)	number of observations
e(df_r)	residual degrees of freedom
e(q)	quantile requested
e(q_v)	value of the quantile
e(reps)	number of replications
e(sum_adev)	sum of absolute deviations
e(sum_rdev)	sum of raw deviations
e(rank)	rank of e(V)
e(convcode)	0 if converged; otherwise, return code for why nonconvergence

Macros

e(cmd)	bsqreg
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(properties)	b V
e(predict)	program used to implement predict
e(marginsnotok)	predictions disallowed by margins

Matrices

e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

_qreg saves the following in r():

Scalars

r(N)	number of observations
r(df_m)	model degrees of freedom
r(q)	quantile requested
r(q_v)	value of the quantile
r(sum_w)	sum of the weights
r(sum_adev)	sum of absolute deviations
r(sum_rdev)	sum of raw deviations
r(f_r)	residual density estimate
r(ic)	number of iterations
r(convcode)	1 if converged, 0 otherwise

Methods and formulas

qreg, iqreg, sqreg, and bsqreg are implemented as ado-files.

According to Stuart and Ord (1991, 1084), the method of minimum absolute deviations was first proposed by Boscovich in 1757 and was later developed by Laplace; Stigler (1986, 39–55) and Hald (1998, 97–103, 112–116) provide historical details. According to Bloomfield and Steiger (1980), Harris (1950) later observed that the problem of minimum absolute deviations could be turned into the linear programming problem that was first implemented by Wagner (1959). Interest has grown in this method because of interest in robust methods. Statistical and computational properties of minimum absolute deviation estimators are surveyed by Narula and Wellington (1982). Hao and Naiman (2007) provide an excellent introduction to quantile-regression methods.

Define q as the quantile to be estimated; the median is $q = 0.5$. For each observation i, let r_i be the residual

$$r_i = y_i - \sum_j \beta_j x_{ij}$$

Define the multiplier h_i

$$h_i = \begin{cases} 2q & \text{if } r_i > 0 \\ 2(1-q) & \text{otherwise} \end{cases}$$

The quantity being minimized with respect to β_j is $\sum_i |r_i| h_i$, so quantiles other than the median are estimated by weighting the residuals. For example, if we want to estimate the 75th percentile, we weight the negative residuals by 0.50 and the positive residuals by 1.50. It can be shown that the criterion is minimized when 75% of the residuals are negative.

This is set up as a linear programming problem and is solved via linear programming techniques, as suggested by Armstrong, Frome, and Kung (1979) and used by courtesy of Marcel Dekker, Inc. The definition of convergence is exact in the sense that no amount of added iterations could improve the solution. Each step is described by a set of observations through which the regression plane passes, called the *basis*. A step is taken by replacing a point in the basis if the sum of weighted absolute deviations can be improved. If this occurs, a line is printed in the iteration log. The linear programming method is started by doing a weighted least-squares (WLS) regression to identify a good set of observations to use as a starting basis. The WLS algorithm for $q = 0.5$ is taken from Schlossmacher (1973) with a generalization for $0 < q < 1$ implied from Hunter and Lange (2000).

The variances are estimated using a method suggested by Koenker and Bassett (1982). This method can be put into a form recommended by Huber (1967) for M estimates, where

$$\text{cov}(\boldsymbol{\beta}) = \mathbf{R}_2^{-1}\mathbf{R}_1\mathbf{R}_2^{-1}$$

$\mathbf{R}_1 = \mathbf{X}'\mathbf{W}\mathbf{W}'\mathbf{X}$ (in the Huber formulation), $\mathbf{W}$ is a diagonal matrix with elements

$$W_{ii} = \begin{cases} q/f_{\text{residuals}}(0) & \text{if } r > 0 \\ (1-q)/f_{\text{residuals}}(0) & \text{if } r < 0 \\ 0 & \text{otherwise} \end{cases}$$

and $\mathbf{R}_2$ is the design matrix $\mathbf{X}'\mathbf{X}$. This is derived from formula 3.11 in Koenker and Bassett, although their notation is much different. $f_{\text{residuals}}()$ refers to the density of the true residuals. Koenker and Bassett leave much unspecified, including how to obtain a density estimate for the errors in real data. At this point, we offer our contribution (Rogers 1993).

We first sort the residuals and locate the observation in the residuals corresponding to the quantile in question, taking into account weights if they are applied. We then calculate w_n, the square root of the sum of the weights. Unweighted data are equivalent to weighted data in which each observation has weight 1, resulting in $w_n = \sqrt{n}$. For analytically weighted data, the weights are rescaled so that the sum of the weights is the number of observations, resulting in $\sqrt{n}$ again. For frequency-weighted data, w_n literally is the square root of the sum of the weights.

We locate the closest observation in each direction, such that the sum of weights for all closer observations is w_n. If we run off the end of the dataset, we stop. We calculate w_s, the sum of weights for all observations in this middle space. Typically, w_s is slightly greater than w_n.

If there are k parameters, then exactly k of the residuals must be zero. Thus we calculate an adjusted weight $w_a = w_s - k$. The density estimate is the distance spanned by these observations divided by w_a. Because the distance spanned by this mechanism converges toward zero, this estimate of density converges in probability to the true density.

The pseudo-R^2 is calculated as

$$1 - \frac{\text{sum of weighted deviations about estimated quantile}}{\text{sum of weighted deviations about raw quantile}}$$

This is based on the likelihood for a double-exponential distribution $e^{h_i|r_i|}$.

Title

qreg postestimation — Postestimation tools for qreg, iqreg, sqreg, and bsqreg

Description

The following postestimation commands are available after `qreg`, `iqreg`, `bsqreg`, and `sqreg`:

Command	Description
`estat`	VCE and estimation sample summary
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

For qreg, iqreg, and bsqreg

```
predict [type] newvar [if] [in] [, [xb|stdp|residuals]]
```

For sqreg

```
predict [type] newvar [if] [in] [, equation(eqno[,eqno]) statistic]
```

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the linear prediction
`stddp`	standard error of the difference in linear predictions
`residuals`	residuals

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`stddp` is allowed only after you have fit a model using `sqreg`. The standard error of the difference in linear predictions ($\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$) between equations 1 and 2 is calculated.

`residuals` calculates the residuals, that is, $y_j - \mathbf{x}_j\mathbf{b}$.

`equation(`*eqno*`[ ,`*eqno*`])` specifies the equation to which you are making the calculation.

`equation()` is filled in with one *eqno* for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

If you do not specify `equation()`, results are the same as if you had specified `equation(#1)`.

To use `stddp`, you must specify two equations. You might specify `equation(#1, #2)` or `equation(q80, q20)` to indicate the 80th and 20th quantiles.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

query — Display system parameters

Syntax

```
query [ memory | output | interface | graphics | efficiency | network |
  update | trace | mata | other ]
```

Description

query displays the settings of various Stata parameters.

Remarks

query provides more system information than you will ever want to know. You do not need to understand every line of output that query produces if all you need is one piece of information. Here is what happens when you type query:

```
. query
------------------------------------------------------------------------------
    Memory settings
        set maxvar          5000        2048-32767; max. vars allowed
        set matsize         400         10-11000; max. # vars in models
        set niceness        5           0-10
        set min_memory      0           0-1600gc
        set max_memory      .           32mc-1600gc or .

    Other settings
        set type            float       may be float or double
        set maxiter         16000       max iterations for estimation commands
        set searchdefault   local       may be local, net, or all
        set seed            X075bcd151f123bb5159a55e50022865746ad
        set varabbrev       on
        set emptycells      keep        may be keep or drop
        set processors      1
-------------------------------------------------------------------------------
```

The output is broken into several divisions: memory, output, interface, graphics, efficiency, network, update, trace, mata, and other settings. We will discuss each one in turn.

We generated the output above using Stata/SE for Windows. Here is what happens when we type `query` and we are running Stata/IC for Mac:

```
. query
-------------------------------------------------------------------------------
    Memory settings
        set maxvar          2048        (not settable in this version of Stata)
        set matsize         400         10-800; max. # vars in model
        set niceness        5           0-10
        set min_memory      0           0-1600g
        set max_memory      .           32m-1600g or .
        set segmentsize     32m         1m-32g
-------------------------------------------------------------------------------
    Output settings
        set more            on
        set rmsg            off
        set dp              period      may be period or comma
        set linesize        80          characters
        set pagesize        25          lines
        ---------------------------------------------------------------------

Memory settings

Memory settings indicate how memory is allocated, the maximum number of variables, and the maximum size of a matrix.

For more information, see

maxvar	[D]	**memory**
matsize	[R]	**matsize**
niceness	[D]	**memory**
min_memory	[D]	**memory**
max_memory	[D]	**memory**
segmentsize	[D]	**memory**

Output settings

Output settings show how Stata displays output on the screen and in log files.

For more information, see

more	[R]	**more**
rmsg	[P]	**rmsg**
dp	[D]	**format**
linesize	[R]	**log**
pagesize	[R]	**more**
level	[R]	**level**
showbaselevels	[R]	**set showbaselevels**
showemptycells	[R]	**set showbaselevels**
showomitted	[R]	**set showbaselevels**
cformat	[R]	**set cformat**
pformat	[R]	**set cformat**
sformat	[R]	**set cformat**
lstretch	[R]	**set**
logtype	[R]	**log**
eolchar	[R]	**set**
notifyuser	[R]	**set**

include_bitmap	[R]	**set**

Interface settings

Interface settings control how Stata's interface works.

For more information, see

dockable	[R] **set**
dockingguides	[R] **set**
floatresults	[R] **set**
floatwindows	[R] **set**
locksplitters	[R] **set**
pinnable	[R] **set**
doublebuffer	[R] **set**
revkeyboard	[R] **set**
varkeyboard	[R] **set**
smoothfonts	[R] **set**
linegap	[R] **set**
scrollbufsize	[R] **set**
fastscroll	[R] **set**
reventries	[R] **set**
maxdb	[R] **db**

Graphics settings

Graphics settings indicate how Stata's graphics are displayed.

For more information, see

graphics	[G-2] **set graphics**
autotabgraphs	[R] **set**
scheme	[G-2] **set scheme**
printcolor	[G-2] **set printcolor**
copycolor	[G-2] **set printcolor**

Efficiency settings

The efficiency settings set the maximum amount of memory allocated to automatically loaded do-files, the maximum number of remembered-contents dialog boxes, and the use of virtual memory.

For more information, see

adosize	[P] **sysdir**

Network settings

Network settings determine how Stata interacts with the Internet.

For more information, see [R] **netio**.

Update settings

Update settings determine how Stata performs updates.

For more information, see [R] **update**.

Trace settings

Trace settings adjust Stata's behavior and are particularly useful in debugging code.

For more information, see [P] **trace**.

Mata settings

Mata settings affect Mata's system parameters.

For more information, see [M-3] **mata set**.

Other settings

The other settings are a miscellaneous collection.

For more information, see

`type`	[D] **generate**
`maxiter`	[R] **maximize**
`searchdefault`	[R] **search**
`seed`	[R] **set seed**
`varabbrev`	[R] **set**
`emptycells`	[R] **set**
`processors`	[R] **set**
`odbcmgr`	[D] **odbc**

In general, the parameters displayed by `query` can be changed by `set`; see [R] **set**.

Title

ranksum — Equality tests on unmatched data

Syntax

Wilcoxon rank-sum test

`ranksum` *varname* [*if*] [*in*] , `by(`*groupvar*`)` [`porder`]

Nonparametric equality-of-medians test

`median` *varname* [*if*] [*in*] [*weight*] , `by(`*groupvar*`)` [*median_options*]

ranksum_options	Description
Main	
* `by(`*groupvar*`)`	grouping variable
`porder`	probability that variable for first group is larger than variable for second group

median_options	Description
Main	
* `by(`*groupvar*`)`	grouping variable
`exact`	perform Fisher's exact test
`medianties(below)`	assign values equal to the median to below group
`medianties(above)`	assign values equal to the median to above group
`medianties(drop)`	drop values equal to the median from the analysis
`medianties(split)`	split values equal to the median equally between the two groups

*`by(`*groupvar*`)` is required.
`by` is allowed with `ranksum` and `median`; see [D] **by**.
`fweights` are allowed with `median`; see [U] **11.1.6 weight**.

Menu

ranksum

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon rank-sum test

median

Statistics > Nonparametric analysis > Tests of hypotheses > K-sample equality-of-medians test

Description

`ranksum` tests the hypothesis that two independent samples (that is, *unmatched* data) are from populations with the same distribution by using the Wilcoxon rank-sum test, which is also known as the Mann–Whitney two-sample statistic (Wilcoxon 1945; Mann and Whitney 1947).

`median` performs a nonparametric *k*-sample test on the equality of medians. It tests the null hypothesis that the *k* samples were drawn from populations with the same median. For two samples, the chi-squared test statistic is computed both with and without a continuity correction.

`ranksum` and `median` are for use with *unmatched* data. For equality tests on matched data, see [R] **signrank**.

Options for ranksum

Main

`by(`*groupvar*`)` is required. It specifies the name of the grouping variable.

`porder` displays an estimate of the probability that a random draw from the first population is larger than a random draw from the second population.

Options for median

Main

`by(`*groupvar*`)` is required. It specifies the name of the grouping variable.

`exact` displays the significance calculated by Fisher's exact test. For two samples, both one- and two-sided probabilities are displayed.

`medianties(below | above | drop | split)` specifies how values equal to the overall median are to be handled. The median test computes the median for *varname* by using all observations and then divides the observations into those falling above the median and those falling below the median. When values for an observation are equal to the sample median, they can be dropped from the analysis by specifying `medianties(drop)`; added to the group above or below the median by specifying `medianties(above)` or `medianties(below)`, respectively; or if there is more than 1 observation with values equal to the median, they can be equally divided into the two groups by specifying `medianties(split)`. If this option is not specified, `medianties(below)` is assumed.

Remarks

▷ Example 1

We are testing the effectiveness of a new fuel additive. We run an experiment with 24 cars: 12 cars with the fuel treatment and 12 cars without. We input these data by creating a dataset with 24 observations. `mpg` records the mileage rating, and `treat` records 0 if the mileage corresponds to untreated fuel and 1 if it corresponds to treated fuel.

```
. use http://www.stata-press.com/data/r12/fuel2
. ranksum mpg, by(treat)
Two-sample Wilcoxon rank-sum (Mann-Whitney) test
      treat |       obs    rank sum    expected
------------+---------------------------------
          0 |        12         128         150
          1 |        12         172         150
------------+---------------------------------
   combined |        24         300         300
```

```
unadjusted variance      300.00
adjustment for ties       -4.04
                        ---------
adjusted variance        295.96
Ho: mpg(treat==0) = mpg(treat==1)
             z =  -1.279
    Prob > |z| =   0.2010
```

These results indicate that the medians are not statistically different at any level smaller than 20.1%. Similarly, the median test,

```
. median mpg, by(treat) exact
Median test
```

Greater than the median	treat 0	1	Total
no	7	5	12
yes	5	7	12
Total	12	12	24

```
          Pearson chi2(1) =   0.6667   Pr = 0.414
           Fisher's exact =                 0.684
   1-sided Fisher's exact =                 0.342
   Continuity corrected:
          Pearson chi2(1) =   0.1667   Pr = 0.683
```

fails to reject the null hypothesis that there is no difference between the two fuel additives.

Compare these results from these two tests with those obtained from the `signrank` and `signtest` where we found significant differences; see [R] **signrank**. An experiment run on 24 different cars is not as powerful as a before-and-after comparison using the same 12 cars.

◁

Saved results

`ranksum` saves the following in `r()`:

Scalars

`r(N_1)`	sample size n_1
`r(N_2)`	sample size n_2
`r(z)`	z statistic
`r(Var_a)`	adjusted variance
`r(group1)`	value of variable for first group
`r(sum_obs)`	actual sum of ranks for first group
`r(sum_exp)`	expected sum of ranks for first group
`r(porder)`	probability that draw from first population is larger than draw from second population

`median` saves the following in `r()`:

Scalars

`r(N)`	sample size
`r(chi2)`	Pearson's χ^2
`r(p)`	significance of Pearson's χ^2
`r(p_exact)`	Fisher's exact p
`r(groups)`	number of groups compared
`r(chi2_cc)`	continuity-corrected Pearson's χ^2
`r(p_cc)`	continuity-corrected significance
`r(p1_exact)`	one-sided Fisher's exact p

Methods and formulas

`ranksum` and `median` are implemented as ado-files.

For a practical introduction to these techniques with an emphasis on examples rather than theory, see Acock (2010), Bland (2000), or Sprent and Smeeton (2007). For a summary of these tests, see Snedecor and Cochran (1989).

Methods and formulas are presented under the following headings:

ranksum
median

ranksum

For the Wilcoxon rank-sum test, there are two independent random variables, X_1 and X_2, and we test the null hypothesis that $X_1 \sim X_2$. We have a sample of size n_1 from X_1 and another of size n_2 from X_2.

The data are then ranked without regard to the sample to which they belong. If the data are tied, averaged ranks are used. Wilcoxon's test statistic (1945) is the sum of the ranks for the observations in the first sample:

$$T = \sum_{i=1}^{n_1} R_{1i}$$

Mann and Whitney's U statistic (1947) is the number of pairs (X_{1i}, X_{2j}) such that $X_{1i} > X_{2j}$. These statistics differ only by a constant:

$$U = T - \frac{n_1(n_1+1)}{2}$$

Again Fisher's principle of randomization provides a method for calculating the distribution of the test statistic, ties or not. The randomization distribution consists of the $\binom{n}{n_1}$ ways to choose n_1 ranks from the set of all $n = n_1 + n_2$ ranks and assign them to the first sample.

It is a straightforward exercise to verify that

$$E(T) = \frac{n_1(n+1)}{2} \qquad \text{and} \qquad \mathrm{Var}(T) = \frac{n_1 n_2 s^2}{n}$$

where s is the standard deviation of the combined ranks, r_i, for both groups:

$$s^2 = \frac{1}{n-1}\sum_{i=1}^{n}(r_i - \overline{r})^2$$

This formula for the variance is exact and holds both when there are no ties and when there are ties and we use averaged ranks. (Indeed, the variance formula holds for the randomization distribution of choosing n_1 numbers from any set of n numbers.)

Using a normal approximation, we calculate

$$z = \frac{T - E(T)}{\sqrt{\mathrm{Var}(T)}}$$

When the `porder` option is specified, the probability

$$p = \frac{U}{n_1 n_2}$$

is computed.

median

The median test examines whether it is likely that two or more samples came from populations with the same median. The null hypothesis is that the samples were drawn from populations with the same median. The alternative hypothesis is that at least one sample was drawn from a population with a different median. The test should be used only with ordinal or interval data.

Assume that there are score values for k independent samples to be compared. The median test is performed by first computing the median score for all observations combined, regardless of the sample group. Each score is compared with this computed grand median and is classified as being above the grand median, below the grand median, or equal to the grand median. Observations with scores equal to the grand median can be dropped, added to the "above" group, added to the "below" group, or split between the two groups.

Once all observations are classified, the data are cast into a $2 \times k$ contingency table, and a Pearson's chi-squared test or Fisher's exact test is performed.

Henry Berthold Mann (1905–2000) was born in Vienna, Austria, where he completed a doctorate in algebraic number theory. He moved to the United States in 1938 and for several years made his livelihood by tutoring in New York. During this time, he proved a celebrated conjecture in number theory and studied statistics at Columbia with Abraham Wald, with whom he wrote three papers. After the war, he taught at Ohio State and the Universities of Wisconsin and Arizona. In addition to his work in number theory and statistics, he made major contributions to algebra and combinatorics.

Donald Ransom Whitney (1915–2007) studied at Oberlin, Princeton, and Ohio State Universities and worked at the latter throughout his career. His PhD thesis under Henry Mann was on nonparametric statistics. It was this work that produced the test that bears their names.

Title

ratio — Estimate ratios

Syntax

Basic syntax

```
ratio [name:] varname [/] varname
```

Full syntax

```
ratio ([name:] varname [/] varname)
      [([name:] varname [/] varname) ...] [if] [in] [weight] [, options]
```

options	Description
Model	
`stdize(`*varname*`)`	variable identifying strata for standardization
`stdweight(`*varname*`)`	weight variable for standardization
`nostdrescale`	do not rescale the standard weight variable
if/in/over	
`over(`*varlist*`[ , nolabel])`	group over subpopulations defined by *varlist*; optionally, suppress group labels
SE/Cluster	
`vce(`*vcetype*`)`	*vcetype* may be `linearized`, `cluster` *clustvar*, `bootstrap`, or `jackknife`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
`noheader`	suppress table header
`nolegend`	suppress table legend
display_options	control column formats and line width
`coeflegend`	display legend instead of statistics

`bootstrap`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] **11.1.10 Prefix commands**.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.
Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.
`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.
`fweights`, `iweights`, and `pweights` are allowed; see [U] **11.1.6 weight**.
`coeflegend` does not appear in the dialog box.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Ratios

Description

`ratio` produces estimates of ratios, along with standard errors.

Options

Model

`stdize(`*varname*`)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(`*varname*`)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

if/in/over

`over(`*varlist* [`, nolabel`]`)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist*.

When this option is supplied with one variable name, such as `over(`*varname*`)`, the value labels of *varname* are used to identify the subpopulations. If *varname* does not have labeled values (or there are unlabeled values), the values themselves are used, provided that they are nonnegative integers. Noninteger values, negative values, and labels that are not valid Stata names are substituted with a default identifier.

When `over()` is supplied with multiple variable names, each subpopulation is assigned a unique default identifier.

`nolabel` requests that value labels attached to the variables identifying the subpopulations be ignored.

SE/Cluster

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(linearized)`, the default, uses the linearized or sandwich estimator of variance.

Reporting

`level(#)`; see [R] **estimation options**.

`noheader` prevents the table header from being displayed. This option implies `nolegend`.

`nolegend` prevents the table legend identifying the subpopulations from being displayed.

display_options: `cformat(%`*fmt*`)` and `nolstretch`; see [R] **estimation options**.

The following option is available with `ratio` but is not shown in the dialog box:

`coeflegend`; see [R] **estimation options**.

Remarks

Example 1

Using the fuel data from example 2 of [R] **ttest**, we estimate the ratio of mileage for the cars without the fuel treatment (mpg1) to those with the fuel treatment (mpg2).

```
. use http://www.stata-press.com/data/r12/fuel
. ratio myratio: mpg1/mpg2
Ratio estimation                 Number of obs    =       12
      myratio: mpg1/mpg2
```

	Ratio	Linearized Std. Err.	[95% Conf.	Interval]
myratio	.9230769	.032493	.8515603	.9945936

Using these results, we can test to see if this ratio is significantly different from one.

```
. test _b[myratio] = 1
 ( 1)  myratio = 1
       F(  1,    11) =    5.60
            Prob > F =    0.0373
```

We find that the ratio is different from one at the 5% significance level but not at the 1% significance level.

◁

Example 2

Using state-level census data, we want to test whether the marriage rate is equal to the death rate.

```
. use http://www.stata-press.com/data/r12/census2
(1980 Census data by state)
. ratio (deathrate: death/pop) (marrate: marriage/pop)
Ratio estimation                 Number of obs    =       50
    deathrate: death/pop
      marrate: marriage/pop
```

	Ratio	Linearized Std. Err.	[95% Conf.	Interval]
deathrate	.0087368	.0002052	.0083244	.0091492
marrate	.0105577	.0006184	.009315	.0118005

```
. test _b[deathrate]  =  _b[marrate]
 ( 1)  deathrate - marrate = 0
       F(  1,    49) =    6.93
            Prob > F =    0.0113
```

◁

Saved results

`ratio` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(N_over)`	number of subpopulations
`e(N_stdize)`	number of standard strata
`e(N_clust)`	number of clusters
`e(k_eq)`	number of equations in `e(b)`
`e(df_r)`	sample degrees of freedom
`e(rank)`	rank of `e(V)`

Macros

`e(cmd)`	`ratio`
`e(cmdline)`	command as typed
`e(varlist)`	*varlist*
`e(stdize)`	*varname* from `stdize()`
`e(stdweight)`	*varname* from `stdweight()`
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output
`e(cluster)`	name of cluster variable
`e(over)`	*varlist* from `over()`
`e(over_labels)`	labels from `over()` variables
`e(over_namelist)`	names from `e(over_labels)`
`e(namelist)`	ratio identifiers
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(properties)`	`b V`
`e(estat_cmd)`	program used to implement `estat`
`e(marginsnotok)`	predictions disallowed by `margins`

Matrices

`e(b)`	vector of mean estimates
`e(V)`	(co)variance estimates
`e(_N)`	vector of numbers of nonmissing observations
`e(_N_stdsum)`	number of nonmissing observations within the standard strata
`e(_p_stdize)`	standardizing proportions
`e(error)`	error code corresponding to `e(b)`

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`ratio` is implemented as an ado-file.

Methods and formulas are presented under the following headings:

The ratio estimator
Survey data
The survey ratio estimator
The standardized ratio estimator
The poststratified ratio estimator
The standardized poststratified ratio estimator
Subpopulation estimation

The ratio estimator

Let $R = Y/X$ be the ratio to be estimated, where Y and X are totals; see [R] **total**. The estimate for R is $\widehat{R} = \widehat{Y}/\widehat{X}$ (the ratio of the sample totals). From the delta method (that is, a first-order Taylor expansion), the approximate variance of the sampling distribution of the linearized $\widehat{R}$ is

$$V(\widehat{R}) \approx \frac{1}{X^2}\left\{V(\widehat{Y}) - 2R\mathrm{Cov}(\widehat{Y},\widehat{X}) + R^2V(\widehat{X})\right\}$$

Direct substitution of $\widehat{X}$, $\widehat{R}$, and the estimated variances and covariance of $\widehat{X}$ and $\widehat{Y}$ leads to the following variance estimator:

$$\widehat{V}(\widehat{R}) = \frac{1}{\widehat{X}^2}\left\{\widehat{V}(\widehat{Y}) - 2\widehat{R}\widehat{\mathrm{Cov}}(\widehat{Y},\widehat{X}) + \widehat{R}^2\widehat{V}(\widehat{X})\right\} \tag{1}$$

Survey data

See [SVY] **variance estimation**, [SVY] **direct standardization**, and [SVY] **poststratification** for discussions that provide background information for the following formulas.

The survey ratio estimator

Let Y_j and X_j be survey items for the jth individual in the population, where $j = 1, \ldots, M$ and M is the size of the population. The associated population ratio for the items of interest is $R = Y/X$ where

$$Y = \sum_{j=1}^{M} Y_j \qquad \text{and} \qquad X = \sum_{j=1}^{M} X_j$$

Let y_j and x_j be the corresponding survey items for the jth sampled individual from the population, where $j = 1, \ldots, m$ and m is the number of observations in the sample.

The estimator $\widehat{R}$ for the population ratio R is $\widehat{R} = \widehat{Y}/\widehat{X}$, where

$$\widehat{Y} = \sum_{j=1}^{m} w_j y_j \qquad \text{and} \qquad \widehat{X} = \sum_{j=1}^{m} w_j x_j$$

and w_j is a sampling weight. The score variable for the ratio estimator is

$$z_j(\widehat{R}) = \frac{y_j - \widehat{R}x_j}{\widehat{X}} = \frac{\widehat{X}y_j - \widehat{Y}x_j}{\widehat{X}^2}$$

The standardized ratio estimator

Let D_g denote the set of sampled observations that belong to the gth standard stratum and define $I_{D_g}(j)$ to indicate if the jth observation is a member of the gth standard stratum; where $g = 1, \ldots, L_D$ and L_D is the number of standard strata. Also, let π_g denote the fraction of the population that belongs to the gth standard stratum, thus $\pi_1 + \cdots + \pi_{L_D} = 1$. Note that π_g is derived from the `stdweight()` option.

The estimator for the standardized ratio is

$$\widehat{R}^D = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g}{\widehat{X}_g}$$

where

$$\widehat{Y}_g = \sum_{j=1}^{m} I_{D_g}(j)\, w_j y_j$$

and $\widehat{X}_g$ is similarly defined. The score variable for the standardized ratio is

$$z_j(\widehat{R}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\widehat{X}_g y_j - \widehat{Y}_g x_j}{\widehat{X}_g^2}$$

The poststratified ratio estimator

Let P_k denote the set of sampled observations that belong to poststratum k, and define $I_{P_k}(j)$ to indicate if the jth observation is a member of poststratum k, where $k = 1, \ldots, L_P$ and L_P is the number of poststrata. Also, let M_k denote the population size for poststratum k. P_k and M_k are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] **svyset**.

The estimator for the poststratified ratio is

$$\widehat{R}^P = \frac{\widehat{Y}^P}{\widehat{X}^P}$$

where

$$\widehat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{P_k}(j)\, w_j y_j$$

and $\widehat{X}^P$ is similarly defined. The score variable for the poststratified ratio is

$$z_j(\widehat{R}^P) = \frac{z_j(\widehat{Y}^P) - \widehat{R}^P z_j(\widehat{X}^P)}{\widehat{X}^P} = \frac{\widehat{X}^P z_j(\widehat{Y}^P) - \widehat{Y}^P z_j(\widehat{X}^P)}{(\widehat{X}^P)^2}$$

where

$$z_j(\widehat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left(y_j - \frac{\widehat{Y}_k}{\widehat{M}_k} \right)$$

and $z_j(\widehat{X}^P)$ is similarly defined.

The standardized poststratified ratio estimator

The estimator for the standardized poststratified ratio is

$$\widehat{R}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^P}{\widehat{X}_g^P}$$

where

$$\widehat{Y}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j)\, w_j y_j$$

and $\widehat{X}_g^P$ is similarly defined. The score variable for the standardized poststratified ratio is

$$z_j(\widehat{R}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{X}_g^P z_j(\widehat{Y}_g^P) - \widehat{Y}_g^P z_j(\widehat{X}_g^P)}{(\widehat{X}_g^P)^2}$$

where

$$z_j(\widehat{Y}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\widehat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and $z_j(\widehat{X}_g^P)$ is similarly defined.

Subpopulation estimation

Let S denote the set of sampled observations that belong to the subpopulation of interest, and define $I_S(j)$ to indicate if the jth observation falls within the subpopulation.

The estimator for the subpopulation ratio is $\widehat{R}^S = \widehat{Y}^S / \widehat{X}^S$, where

$$\widehat{Y}^S = \sum_{j=1}^{m} I_S(j)\, w_j y_j \qquad \text{and} \qquad \widehat{X}^S = \sum_{j=1}^{m} I_S(j)\, w_j x_j$$

Its score variable is

$$z_j(\widehat{R}^S) = I_S(j) \frac{y_j - \widehat{R}^S x_j}{\widehat{X}^S} = I_S(j) \frac{\widehat{X}^S y_j - \widehat{Y}^S x_j}{(\widehat{X}^S)^2}$$

The estimator for the standardized subpopulation ratio is

$$\widehat{R}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^S}{\widehat{X}_g^S}$$

where

$$\widehat{Y}_g^S = \sum_{j=1}^{m} I_{D_g}(j) I_S(j)\, w_j y_j$$

and $\widehat{X}_g^S$ is similarly defined. Its score variable is

$$z_j(\widehat{R}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\widehat{X}_g^S y_j - \widehat{Y}_g^S x_j}{(\widehat{X}_g^S)^2}$$

The estimator for the poststratified subpopulation ratio is

$$\widehat{R}^{PS} = \frac{\widehat{Y}^{PS}}{\widehat{X}^{PS}}$$

where

$$\widehat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{P_k}(j) I_S(j)\, w_j y_j$$

and $\widehat{X}^{PS}$ is similarly defined. Its score variable is

$$z_j(\widehat{R}^{PS}) = \frac{\widehat{X}^{PS} z_j(\widehat{Y}^{PS}) - \widehat{Y}^{PS} z_j(\widehat{X}^{PS})}{(\widehat{X}^{PS})^2}$$

where

$$z_j(\widehat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j)\, y_j - \frac{\widehat{Y}_k^S}{\widehat{M}_k} \right\}$$

and $z_j(\widehat{X}^{PS})$ is similarly defined.

The estimator for the standardized poststratified subpopulation ratio is

$$\widehat{R}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^{PS}}{\widehat{X}_g^{PS}}$$

where

$$\widehat{Y}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) I_S(j)\, w_j y_j$$

and $\widehat{X}_g^{PS}$ is similarly defined. Its score variable is

$$z_j(\widehat{R}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{X}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{X}_g^{PS})}{(\widehat{X}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j)\, y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k} \right\}$$

and $z_j(\widehat{X}_g^{PS})$ is similarly defined.

Title

ratio postestimation — Postestimation tools for ratio

Description

The following postestimation commands are available after `ratio`:

Command	Description
`estat`	VCE
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

Remarks

For examples of the use of `test` after `ratio`, see [R] **ratio**.

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

Title

reg3 — Three-stage estimation for systems of simultaneous equations

Syntax

Basic syntax

```
reg3 (depvar1 varlist1) (depvar2 varlist2) ... (depvarN varlistN) [if] [in] [weight]
```

Full syntax

```
reg3 ([eqname1:]depvar1a [depvar1b ...=] varlist1 [, noconstant])
    ([eqname2:]depvar2a [depvar2b ...=] varlist2 [, noconstant])
    ...
    ([eqnameN:]depvarNa [depvarNb ...=] varlistN [, noconstant])
    [if] [in] [weight] [, options]
```

options	Description
Model	
ireg3	iterate until estimates converge
constraints(*constraints*)	apply specified linear constraints
Model 2	
exog(*varlist*)	exogenous variables not specified in system equations
endog(*varlist*)	additional right-hand-side endogenous variables
inst(*varlist*)	full list of exogenous variables
allexog	all right-hand-side variables are exogenous
noconstant	suppress constant from instrument list
Est. method	
3sls	three-stage least squares; the default
2sls	two-stage least squares
ols	ordinary least squares (OLS)
sure	seemingly unrelated regression estimation (SURE)
mvreg	sure with OLS degrees-of-freedom adjustment
corr(*correlation*)	unstructured or independent correlation structure; default is unstructured
df adj.	
small	report small-sample statistics
dfk	use small-sample adjustment
dfk2	use alternate adjustment

Reporting	
level(#)	set confidence level; default is level(95)
first	report first-stage regression
nocnsreport	do not display constraints
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
Optimization	
optimization_options	control the optimization process; seldom used
noheader	suppress display of header
notable	suppress display of coefficient table
nofooter	suppress display of footer
coeflegend	display legend instead of statistics

varlist$_1$, ..., *varlist*$_N$ and the exog() and the inst() varlist may contain factor variables; see [U] **11.4.3 Factor variables**. You must have the same levels of factor variables in all equations that have factor variables.

depvar and *varlist* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, jackknife, rolling, and statsby are allowed; see [U] **11.1.10 Prefix commands**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

aweights are not allowed with the jackknife prefix; see [R] **jackknife**.

aweights and fweights are allowed; see [U] **11.1.6 weight**.

noheader, notable, nofooter, and coeflegend do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Explicit equation naming (*eqname*:) cannot be combined with multiple dependent variables in an equation specification.

Menu

Statistics > Endogenous covariates > Three-stage least squares

Description

reg3 estimates a system of structural equations, where some equations contain endogenous variables among the explanatory variables. Estimation is via three-stage least squares (3SLS); see Zellner and Theil (1962). Typically, the endogenous explanatory variables are dependent variables from other equations in the system. reg3 supports iterated GLS estimation and linear constraints.

reg3 can also estimate systems of equations by seemingly unrelated regression estimation (SURE), multivariate regression (MVREG), and equation-by-equation ordinary least squares (OLS) or two-stage least squares (2SLS).

Nomenclature

Under 3SLS or 2SLS estimation, a *structural equation* is defined as one of the equations specified in the system. A *dependent variable* will have its usual interpretation as the left-hand-side variable in an equation with an associated disturbance term. All dependent variables are explicitly taken to be *endogenous* to the system and are treated as correlated with the disturbances in the system's equations. Unless specified in an endog() option, all other variables in the system are treated as *exogenous* to the system and uncorrelated with the disturbances. The exogenous variables are taken to be *instruments* for the endogenous variables.

Options

Model

`ireg3` causes `reg3` to iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Although the iteration is usually successful, there is no guarantee that it will converge to a stable point. Under SURE, this iteration converges to the maximum likelihood estimates.

`constraints(`*constraints*`)`; see [R] **estimation options**.

Model 2

`exog(`*varlist*`)` specifies additional exogenous variables that are included in none of the system equations. This can occur when the system contains identities that are not estimated. If implicitly exogenous variables from the equations are listed here, `reg3` will just ignore the additional information. Specified variables will be added to the exogenous variables in the system and used in the first stage as instruments for the endogenous variables. By specifying dependent variables from the structural equations, you can use `exog()` to override their endogeneity.

`endog(`*varlist*`)` identifies variables in the system that are not dependent variables but are endogenous to the system. These variables must appear in the variable list of at least one equation in the system. Again the need for this identification often occurs when the system contains identities. For example, a variable that is the sum of an exogenous variable and a dependent variable may appear as an explanatory variable in some equations.

`inst(`*varlist*`)` specifies a full list of all exogenous variables and may not be used with the `endog()` or `exog()` options. It must contain a full list of variables to be used as instruments for the endogenous regressors. Like `exog()`, the list may contain variables not specified in the system of equations. This option can be used to achieve the same results as the `endog()` and `exog()` options, and the choice is a matter of convenience. Any variable not specified in the *varlist* of the `inst()` option is assumed to be endogenous to the system. As with `exog()`, including the dependent variables from the structural equations will override their endogeneity.

`allexog` indicates that all right-hand-side variables are to be treated as exogenous—even if they appear as the dependent variable of another equation in the system. This option can be used to enforce a SURE or MVREG estimation even when some dependent variables appear as regressors.

`noconstant`; see [R] **estimation options**.

Est. method

`3sls` specifies the full 3SLS estimation of the system and is the default for `reg3`.

`2sls` causes `reg3` to perform equation-by-equation 2SLS on the full system of equations. This option implies `dfk`, `small`, and `corr(independent)`.

Cross-equation testing should not be performed after estimation with this option. With `2sls`, no covariance is estimated between the parameters of the equations. For cross-equation testing, use `3sls`.

`ols` causes `reg3` to perform equation-by-equation OLS on the system—even if dependent variables appear as regressors or the regressors differ for each equation; see [R] **mvreg**. `ols` implies `allexog`, `dfk`, `small`, and `corr(independent)`; `nodfk` and `nosmall` may be specified to override `dfk` and `small`.

The covariance of the coefficients between equations is not estimated under this option, and cross-equation tests should not be performed after estimation with `ols`. For cross-equation testing, use `sure` or `3sls` (the default).

`sure` causes `reg3` to perform a SURE of the system—even if dependent variables from some equations appear as regressors in other equations; see [R] **sureg**. `sure` is a synonym for `allexog`.

`mvreg` is identical to `sure`, except that the disturbance covariance matrix is estimated with an OLS degrees-of-freedom adjustment—the `dfk` option. If the regressors are identical for all equations, the parameter point estimates will be the standard MVREG results. If any of the regressors differ, the point estimates are those for SURE with an OLS degrees-of-freedom adjustment in computing the covariance matrix. `nodfk` and `nosmall` may be specified to override `dfk` and `small`.

`corr(`*correlation*`)` specifies the assumed form of the correlation structure of the equation disturbances and is rarely requested explicitly. For the family of models fit by `reg3`, the only two allowable correlation structures are `unstructured` and `independent`. The default is `unstructured`.

This option is used almost exclusively to estimate a system of equations by 2SLS or to perform OLS regression with `reg3` on multiple equations. In these cases, the correlation is set to `independent`, forcing `reg3` to treat the covariance matrix of equation disturbances as diagonal in estimating model parameters. Thus a set of two-stage coefficient estimates can be obtained if the system contains endogenous right-hand-side variables, or OLS regression can be imposed, even if the regressors differ across equations. Without imposing independent disturbances, `reg3` would estimate the former by 3SLS and the latter by SURE.

Any tests performed after estimation with the `independent` option will treat coefficients in different equations as having no covariance; cross-equation tests should not be used after specifying `corr(independent)`.

df adj.

`small` specifies that small-sample statistics be computed. It shifts the test statistics from χ^2 and z statistics to F statistics and t statistics. This option is intended primarily to support MVREG. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the t statistics are all taken to be those for the first equation. This approach poses no problem under MVREG because the regressors are the same across equations.

`dfk` specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, `reg3` by default uses the number of sample observations n as a divisor. When the `dfk` option is set, a small-sample adjustment is made, and the divisor is taken to be $\sqrt{(n-k_i)(n-k_j)}$, where k_i and k_j are the numbers of parameters in equations i and j, respectively.

`dfk2` specifies the use of an alternative divisor in computing the covariance matrix for the equation errors. When the `dfk2` option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

Reporting

`level(#)`; see [R] **estimation options**.

`first` requests that the first-stage regression results be displayed during estimation.

`nocnsreport`; see [R] **estimation options**.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Optimization

optimization_options control the iterative process that minimizes the sum of squared errors when `ireg3` is specified. These options are seldom used.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals #, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default value of `iterate()` is the current value of `set maxiter` (see [R] **maximize**), which is `iterate(16000)` if `maxiter` has not been changed.

`trace` adds to the iteration log a display of the current parameter vector.

`nolog` suppresses the display of the iteration log.

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to #, the optimization process is stopped. `tolerance(1e-6)` is the default.

The following options are available with `reg3` but are not shown in the dialog box:

`noheader` suppresses display of the header reporting the estimation method and the table of equation summary statistics.

`notable` suppresses display of the coefficient table.

`nofooter` suppresses display of the footer reporting the list of endogenous and exogenous variables in the model.

`coeflegend`; see [R] **estimation options**.

Remarks

`reg3` estimates systems of structural equations where some equations contain endogenous variables among the explanatory variables. Generally, these endogenous variables are the dependent variables of other equations in the system, though not always. The disturbance is correlated with the endogenous variables—violating the assumptions of OLS. Further, because some of the explanatory variables are the dependent variables of other equations in the system, the error terms among the equations are expected to be correlated. `reg3` uses an instrumental-variables approach to produce consistent estimates and generalized least squares (GLS) to account for the correlation structure in the disturbances across the equations. Good general references on three-stage estimation include Davidson and MacKinnon (1993, 651–661) and Greene (2012, 331–334).

Three-stage least squares can be thought of as producing estimates from a three-step process.

Step 1. Develop instrumented values for all endogenous variables. These instrumented values can simply be considered as the predicted values resulting from a regression of each endogenous variable on all exogenous variables in the system. This stage is identical to the first step in 2SLS and is critical for the consistency of the parameter estimates.

Step 2. Obtain a consistent estimate for the covariance matrix of the equation disturbances. These estimates are based on the residuals from a 2SLS estimation of each structural equation.

Step 3. Perform a GLS-type estimation using the covariance matrix estimated in the second stage and with the instrumented values in place of the right-hand-side endogenous variables.

❑ Technical note

The estimation and use of the covariance matrix of disturbances in three-stage estimation is almost identical to the SURE method—`sureg`. As with SURE, using this covariance matrix improves the efficiency of the three-stage estimator. Even without the covariance matrix, the estimates would be consistent. (They would be 2SLS estimates.) This improvement in efficiency comes with a caveat. All the parameter estimates now depend on the consistency of the covariance matrix estimates. If one equation in the system is misspecified, the disturbance covariance estimates will be inconsistent, and the resulting coefficients will be biased and inconsistent. Alternatively, if each equation is estimated separately by 2SLS ([R] **regress**), only the coefficients in the misspecified equation are affected.

❑

❑ Technical note

If an equation is just identified, the 3SLS point estimates for that equation are identical to the 2SLS estimates. However, as with `sureg`, even if all equations are just identified, fitting the model via `reg3` has at least one advantage over fitting each equation separately via `ivregress`; by using `reg3`, tests involving coefficients in different equations can be performed easily using `test` or `testnl`.

❑

▷ Example 1

A simple macroeconomic model relates consumption (`consump`) to private and government wages paid (`wagepriv` and `wagegovt`). Simultaneously, private wages depend on consumption, total government expenditures (`govt`), and the lagged stock of capital in the economy (`capital1`). Although this is not a plausible model, it does meet the criterion of being simple. This model could be written as

$$\texttt{consump} = \beta_0 + \beta_1\,\texttt{wagepriv} + \beta_2\,\texttt{wagegovt} + \epsilon_1$$

$$\texttt{wagepriv} = \beta_3 + \beta_4\,\texttt{consump} + \beta_5\,\texttt{govt} + \beta_6\,\texttt{capital1} + \epsilon_2$$

If we assume that this is the full system, `consump` and `wagepriv` will be endogenous variables, with `wagegovt`, `govt`, and `capital1` exogenous. Data for the U.S. economy on these variables are taken from Klein (1950). This model can be fit with `reg3` by typing

```
. use http://www.stata-press.com/data/r12/klein
. reg3 (consump wagepriv wagegovt) (wagepriv consump govt capital1)
Three-stage least-squares regression
```

Equation	Obs	Parms	RMSE	"R-sq"	chi2	P
consump	22	2	1.776297	0.9388	208.02	0.0000
wagepriv	22	3	2.372443	0.8542	80.04	0.0000

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]
consump						
wagepriv	.8012754	.1279329	6.26	0.000	.5505314	1.052019
wagegovt	1.029531	.3048424	3.38	0.001	.432051	1.627011
_cons	19.3559	3.583772	5.40	0.000	12.33184	26.37996
wagepriv						
consump	.4026076	.2567312	1.57	0.117	-.1005764	.9057916
govt	1.177792	.5421253	2.17	0.030	.1152461	2.240338
capital1	-.0281145	.0572111	-0.49	0.623	-.1402462	.0840173
_cons	14.63026	10.26693	1.42	0.154	-5.492552	34.75306

```
Endogenous variables:  consump wagepriv
Exogenous variables:   wagegovt govt capital1
```

Without showing the 2SLS results, we note that the consumption function in this system falls under the conditions noted earlier. That is, the 2SLS and 3SLS coefficients for the equation are identical.

◁

▷ Example 2

Some of the most common simultaneous systems encountered are supply-and-demand models. A simple system could be specified as

$$\texttt{qDemand} = \beta_0 + \beta_1\,\texttt{price} + \beta_2\,\texttt{pcompete} + \beta_3\,\texttt{income} + \epsilon_1$$
$$\texttt{qSupply} = \beta_4 + \beta_5\,\texttt{price} + \beta_6\,\texttt{praw} + \epsilon_2$$
$$\texttt{Equilibrium condition: quantity} = \texttt{qDemand} = \texttt{qSupply}$$

where

`quantity` is the quantity of a product produced and sold,
`price` is the price of the product,
`pcompete` is the price of a competing product,
`income` is the average income level of consumers, and
`praw` is the price of raw materials used to produce the product.

In this system, price is assumed to be determined simultaneously with demand. The important statistical implications are that price is not a predetermined variable and that it is correlated with the disturbances of both equations. The system is somewhat unusual: quantity is associated with two disturbances. This fact really poses no problem because the disturbances are specified on the behavioral demand and supply equations—two separate entities. Often one of the two equations is rewritten to place price on the left-hand side, making this endogeneity explicit in the specification.

To provide a concrete illustration of the effects of simultaneous equations, we can simulate data for the above system by using known coefficients and disturbance properties. Specifically, we will simulate the data as

$$\texttt{qDemand} = 40 - 1.0\,\texttt{price} + 0.25\,\texttt{pcompete} + 0.5\,\texttt{income} + \epsilon_1$$

$$\texttt{qSupply} = 0.5\,\texttt{price} - 0.75\,\texttt{praw} + \epsilon_2$$

where

$$\epsilon_1 \sim N(0, 2.4)$$

$$\epsilon_2 \sim N(0, 3.8)$$

For comparison, we can estimate the supply and demand equations separately by OLS. The estimates for the demand equation are

```
. use http://www.stata-press.com/data/r12/supDem
. regress quantity price pcompete income

Examining the coefficients from these regressions, we note that they are not close to the known parameters used to generate the simulated data. In particular, the positive coefficient on `price` in the demand equation stands out. We constructed our simulated data to be consistent with economic theory—people demand less of a product if its price rises and more if their personal income rises. Although the `price` coefficient is statistically insignificant, the positive value contrasts starkly with what is predicted from economic price theory and the -1.0 value that we used in the simulation. Likewise, we are disappointed with the insignificance and level of the coefficient on average `income`. The supply equation has correct signs on the two main parameters, but their levels are different from the known values. In fact, the coefficient on `price` (0.724675) is different from the simulated parameter (0.5) at the 5% level of significance.

All these problems are to be expected. We explicitly constructed a simultaneous system of equations that violated one of the assumptions of least squares. Specifically, the disturbances were correlated with one of the regressors—`price`.

Two-stage least squares can be used to address the correlation between regressors and disturbances. Using instruments for the endogenous variable, `price`, 2SLS will produce consistent estimates of the parameters in the system. Let's use `ivregress` (see [R] **ivregress**) to see how our simulated system behaves when fit using 2SLS.

```

We are now much happier with the estimation results. All the coefficients from both equations are close to the true parameter values for the system. In particular, the coefficients are all well within 95% confidence intervals for the parameters. The missing R-squared in the demand equation seems unusual; we will discuss that more later.

Finally, this system could be estimated using 3SLS. To demonstrate how large systems might be handled and to avoid multiline commands, we will use global macros (see [P] **macro**) to hold the specifications for our equations.

```
. global demand "(qDemand: quantity price pcompete income)"
. global supply "(qSupply: quantity price praw)"
. reg3 $demand $supply, endog(price)
```

We must specify `price` as endogenous because it does not appear as a dependent variable in either equation. Without this option, `reg3` would assume that there are no endogenous variables in the system and produce seemingly unrelated regression (`sureg`) estimates. The `reg3` output from our series of commands is

```
Three-stage least-squares regression

```

The use of 3SLS over 2SLS is essentially an efficiency issue. The coefficients of the demand equation from 3SLS are close to the coefficients from two-stage least squares, and those of the supply equation are identical. The latter case was mentioned earlier for systems with some exactly identified equations. However, even for the demand equation, we do not expect the coefficients to change systematically. What we do expect from three-stage least squares are more precise estimates of the parameters given the validity of our specification and `reg3`'s use of the covariances among the disturbances.

Let's summarize the results. With OLS, we got obviously biased estimates of the parameters. No amount of data would have improved the OLS estimates—they are inconsistent in the face of the violated OLS assumptions. With 2SLS, we obtained consistent estimates of the parameters, and these would have improved with more data. With 3SLS, we obtained consistent estimates of the parameters that are more efficient than those obtained by 2SLS.

◁

❑ Technical note

We noted earlier that the R-squared was missing from the two-stage estimates of the demand equation. Now we see that the R-squared is negative for the three-stage estimates of the same equation. How can we have a negative R-squared?

In most estimators, other than least squares, the R-squared is no more than a summary measure of the overall in-sample predictive power of the estimator. The computational formula for R-squared is $R\text{-squared} = 1 - \text{RSS}/\text{TSS}$, where RSS is the residual sum of squares (sum of squared residuals) and TSS is the total sum of squared deviations about the mean of the dependent variable. In a standard linear model with a constant, the model from which the TSS is computed is nested within the full model from which RSS is computed—they both have a constant term based on the same data. Thus it must be that $\text{TSS} \geq \text{RSS}$ and R-squared is constrained between 0 and 1.

For 2SLS and 3SLS, some of the regressors enter the model as instruments when the parameters are estimated. However, because our goal is to fit the structural model, the actual values, not the instruments for the endogenous right-hand-side variables, are used to determine R-squared. The model residuals are computed over a different set of regressors from those used to fit the model. The two-

or three-stage estimates are no longer nested within a constant-only model of the dependent variable, and the residual sum of squares is no longer constrained to be smaller than the total sum of squares.

A negative R-squared in 3SLS should be taken for exactly what it is—an indication that the structural model predicts the dependent variable worse than a constant-only model. Is this a problem? It depends on the application. Three-stage least squares applied to our contrived supply-and-demand example produced good estimates of the known true parameters. Still, the demand equation produced an R-squared of -0.854. How do we feel about our parameter estimates? This should be determined by the estimates themselves, their associated standard errors, and the overall model significance. On this basis, negative R-squared and all, we feel pretty good about all the parameter estimates for both the supply and demand equations. Would we want to make predictions about equilibrium quantity by using the demand equation alone? Probably not. Would we want to make these quantity predictions by using the supply equation? Possibly, because based on in-sample predictions, they seem better than those from the demand equations. However, both the supply and demand estimates are based on limited information. If we are interested in predicting quantity, a reduced-form equation containing all our independent variables would usually be preferred.

❑

❑ Technical note

As a matter of syntax, we could have specified the supply-and-demand model on one line without using global macros.

```
. reg3 (quantity price pcompete income) (quantity price praw), endog(price)
Three-stage least-squares regression
```

Equation	Obs	Parms	RMSE	"R-sq"	chi2	P

```
Endogenous variables:  quantity price
Exogenous variables:   pcompete income praw
```

However, here `reg3` has been forced to create a unique equation name for the supply equation—`2quantity`. Both the supply and demand equations could not be designated as `quantity`, so a number was prefixed to the name for the supply equation.

We could have specified

```
. reg3 (qDemand: quantity price pcompete income) (qSupply: quantity price praw),
> endog(price)
```

and obtained the same results and equation labeling as when we used global macros to hold the equation specifications.

Without explicit equation names, `reg3` always assumes that the dependent variable should be used to name equations. When each equation has a different dependent variable, this rule causes no problems and produces easily interpreted result tables. If the same dependent variable appears in more than one equation, however, `reg3` will create a unique equation name based on the dependent variable name. Because equation names must be used for cross-equation tests, you have more control in this situation if explicit names are placed on the equations.

❑

▷ Example 3: Using the full syntax of reg3

Klein's (1950) model of the U.S. economy is often used to demonstrate system estimators. It contains several common features that will serve to demonstrate the full syntax of `reg3`. The Klein model is defined by the following seven relationships:

$$\mathtt{c} = \beta_0 + \beta_1\mathtt{p} + \beta_2\mathtt{p1} + \beta_3\mathtt{w} + \epsilon_1 \tag{1}$$
$$\mathtt{i} = \beta_4 + \beta_5\mathtt{p} + \beta_6\mathtt{p1} + \beta_7\mathtt{k1} + \epsilon_2 \tag{2}$$
$$\mathtt{wp} = \beta_8 + \beta_9\mathtt{y} + \beta_{10}\mathtt{y1} + \beta_{11}\mathtt{yr} + \epsilon_3 \tag{3}$$
$$\mathtt{y} = \mathtt{c} + \mathtt{i} + \mathtt{g} \tag{4}$$
$$\mathtt{p} = \mathtt{y} - \mathtt{t} - \mathtt{wp} \tag{5}$$
$$\mathtt{k} = \mathtt{k1} + \mathtt{i} \tag{6}$$
$$\mathtt{w} = \mathtt{wg} + \mathtt{wp} \tag{7}$$

The variables in the model are listed below. Two sets of variable names are shown. The concise first name uses traditional economics mnemonics, whereas the second name provides more guidance for everyone else. The concise names serve to keep the specification of the model small (and quite understandable to economists).

Short name	Long name	Variable definition	Type
c	consump	Consumption	endogenous
p	profits	Private industry profits	endogenous
p1	profits1	Last year's private industry profits	exogenous
wp	wagepriv	Private wage bill	endogenous
wg	wagegovt	Government wage bill	exogenous
w	wagetot	Total wage bill	endogenous
i	invest	Investment	endogenous
k1	capital1	Last year's level of capital stock	exogenous
y	totinc	Total income/demand	endogenous
y1	totinc1	Last year's total income	exogenous
g	govt	Government spending	exogenous
t	taxnetx	Indirect bus. taxes + net exports	exogenous
yr	year	Year—1931	exogenous

Equations (1)–(3) are behavioral and contain explicit disturbances (ϵ_1, ϵ_2, and ϵ_3). The remaining equations are identities that specify additional variables in the system and their accounting relationships with the variables in the behavioral equations. Some variables are explicitly endogenous by appearing as dependent variables in (1)–(3). Others are implicitly endogenous as linear combinations that contain other endogenous variables (for example, `w` and `p`). Still other variables are implicitly exogenous by appearing in the identities but not in the behavioral equations (for example, `wg` and `g`).

Using the concise names, we can fit Klein's model with the following command:

```
. use http://www.stata-press.com/data/r12/kleinAbr
. reg3 (c p p1 w) (i p p1 k1) (wp y y1 yr), endog(w p y) exog(t wg g)
Three-stage least-squares regression
```

_cons	16.44079	1.304549	12.60	0.000	13.88392	18.99766
i						
p	-.0130791	.1618962	-0.08	0.936	-.3303898	.3042316
p1	.7557238	.1529331	4.94	0.000	.4559805	1.055467
k1	-.1948482	.0325307	-5.99	0.000	-.2586072	-.1310893
_cons	28.17785	6.793768	4.15	0.000	14.86231	41.49339
wp						
y	.4004919	.0318134	12.59	0.000	.3381388	.462845
y1	.181291	.0341588	5.31	0.000	.1143411	.2482409
yr	.149674	.0279352	5.36	0.000	.094922	.2044261
_cons	1.797216	1.115854	1.61	0.107	-.3898181	3.984251

```
Endogenous variables:  c i wp w p y
Exogenous variables:   p1 k1 y1 yr t wg g
```

We used the `exog()` option to identify `t`, `wg`, and `g` as exogenous variables in the system. These variables must be identified because they are part of the system but appear directly in none of the behavioral equations. Without this option, `reg3` would not know they were part of the system. The `endog()` option specifying `w`, `p`, and `y` is also required. Without this information, `reg3` would be unaware that these variables are linear combinations that include endogenous variables.

❑ Technical note

Rather than listing additional endogenous and exogenous variables, we could specify the full list of exogenous variables in an `inst()` option,

```
. reg3 (c p p1 w) (i p p1 k1) (wp y y1 yr), inst(g t wg yr p1 k1 y1)
```

or equivalently,

```
. global conseqn "(c p p1 w)"
. global inveqn  "(i p p1 k1)"
. global wageqn  "(wp y y1 yr)"
. global inlist  "g t wg yr p1 k1 y1"
. reg3 $conseqn $inveqn $wageqn, inst($inlist)
```

Macros and explicit equations can also be mixed in the specification

```
. reg3 $conseqn (i p p1 k1) $wageqn, endog(w p y) exog(t wg g)
```

or

```
. reg3 (c p p1 w) $inveqn (wp y y1 yr), endog(w p y) exog(t wg g)
```

Placing the equation-binding parentheses in the global macros was also arbitrary. We could have used

```
. global consump  "c p p1 w"
. global invest   "i p p1 k1"
. global wagepriv "wp y y1 yr"
. reg3 ($consump) ($invest) ($wagepriv), endog(w p y) exog(t wg g)
```

`reg3` is tolerant of all combinations, and these commands will produce identical output.

❑

Switching to the full variable names, we can fit Klein's model with the commands below. We will use global macros to store the lists of endogenous and exogenous variables. Again this is not necessary: these lists could have been typed directly on the command line. However, assigning the lists to local macros makes additional processing easier if alternative models are to be fit. We will also use the `ireg3` option to produce the iterated estimates.

▷ Example 4: Constraints with reg3

As a simple example of constraints, (1) above may be rewritten with both wages explicitly appearing (rather than as a variable containing the sum). Using the longer variable names, we have

$$\texttt{consump} = \beta_0 + \beta_1\,\texttt{profits} + \beta_2\,\texttt{profits1} + \beta_3\,\texttt{wagepriv} + \beta_{12}\,\texttt{wagegovt} + \epsilon_1$$

To retain the effect of the identity in (7), we need $\beta_3 = \beta_{12}$ as a constraint on the system. We obtain this result by defining the constraint in the usual way and then specifying its use in `reg3`. Because `reg3` is a system estimator, we will need to use the full equation syntax of `constraint`. The assumption that the following commands are entered after the model above has been estimated. We are simply changing the definition of the consumption equation (`consump`) and adding a constraint on two of its parameters. The rest of the model definition is carried forward.

```
. global conseqn "(consump profits profits1 wagepriv wagegovt)"
. constraint 1 [consump]wagepriv = [consump]wagegovt
. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1) ireg3
note:  additional endogenous variables not in the system have no effect
       and are ignored:  wagetot
Iteration 1:   tolerance =   .3712547
Iteration 2:   tolerance =    .189471
Iteration 3:   tolerance =     .10764
  (output omitted)
Iteration 24:   tolerance =  7.049e-07
```

```

As expected, none of the parameter or standard error estimates has changed from the previous estimates (before the seventh significant digit). We have simply decomposed the total wage variable into its two parts and constrained the coefficients on these parts. The warning about additional endogenous variables was just `reg3`'s way of letting us know that we had specified some information that was irrelevant to the estimation of the system. We had left the `wagetot` variable in our `endog` macro. It does not mean anything to the system to specify `wagetot` as endogenous because it is no longer in the system. That's fine with `reg3` and fine for our current purposes.

We can also impose constraints across the equations. For example, the admittedly meaningless constraint of requiring `profits` to have the same effect in both the consumption and investment equations could be imposed. Retaining the constraint on the wage coefficients, we would estimate this constrained system.

```
. constraint 2 [consump]profits = [invest]profits

. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1 2) ireg3

❑ Technical note

Identification in a system of simultaneous equations involves the notion that there is enough information to estimate the parameters of the model given the specified functional form. Underidentification usually manifests itself as one matrix in the 3SLS computations. The most commonly violated order condition for 2SLS or 3SLS involves the number of endogenous and exogenous variables. There must be at least as many noncollinear exogenous variables in the remaining system as there are endogenous right-hand-side variables in an equation. This condition must hold for each structural equation in the system.

Put as a set of rules the following:

1. Count the number of right-hand-side endogenous variables in an equation and call this m_i.
2. Count the number of exogenous variables in the same equation and call this k_i.
3. Count the total number of exogenous variables in all the structural equations plus any additional variables specified in an `exog()` or `inst()` option and call this K.
4. If $m_i > (K - k_i)$ for any structural equation (i), then the system is underidentified and cannot be estimated by 3SLS.

We are also possibly in trouble if any of the exogenous variables are linearly dependent. We must have m_i linearly independent variables among the exogenous variables represented by $(K - k_i)$.

The complete conditions for identification involve rank-order conditions on several matrices. For a full treatment, see Theil (1971) or Greene (2012, 331–334).

Saved results

reg3 saves the following in e():

Scalars

e(N)	number of observations
e(k)	number of parameters
e(k_eq)	number of equations in e(b)
e(mss_#)	model sum of squares for equation #
e(df_m#)	model degrees of freedom for equation #
e(rss_#)	residual sum of squares for equation #
e(df_r)	residual degrees of freedom (small)
e(r2_#)	R-squared for equation #
e(F_#)	F statistic for equation # (small)
e(rmse_#)	root mean squared error for equation #
e(dfk2_adj)	divisor used with VCE when dfk2 specified
e(ll)	log likelihood
e(chi2_#)	χ^2 for equation #
e(p_#)	significance for equation #
e(cons_#)	1 when equation # has a constant, 0 otherwise
e(rank)	rank of e(V)
e(ic)	number of iterations

Macros

e(cmd)	reg3
e(cmdline)	command as typed
e(depvar)	names of dependent variables
e(exog)	names of exogenous variables
e(endog)	names of endogenous variables
e(eqnames)	names of equations
e(corr)	correlation structure
e(wtype)	weight type
e(wexp)	weight expression
e(method)	3sls, 2sls, ols, sure, or mvreg
e(small)	small
e(dfk)	dfk, if specified
e(properties)	b V
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(Sigma)	$\widehat{\Sigma}$ matrix
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

Methods and formulas

`reg3` is implemented as an ado-file.

The most concise way to represent a system of equations for 3SLS requires thinking of the individual equations and their associated data as being stacked. `reg3` does not expect the data in this format, but it is a convenient shorthand. The system could then be formulated as

$$\begin{bmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_M \end{bmatrix} = \begin{bmatrix} \mathbf{Z}_1 & 0 & \dots & 0 \\ 0 & \mathbf{Z}_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \mathbf{Z}_M \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_M \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_M \end{bmatrix}$$

In full matrix notation, this is just

$$\mathbf{y} = \mathbf{Z}\,\mathbf{B} + \epsilon$$

The $\mathbf{Z}$ elements in these matrices represent both the endogenous and the exogenous right-hand-side variables in the equations.

Also assume that there will be correlation between the disturbances of the equations so that

$$E(\epsilon\epsilon') = \mathbf{\Sigma}$$

where the disturbances are further assumed to have an expected value of 0; $E(\epsilon) = 0$.

The first stage of 3SLS regression requires developing instrumented values for the endogenous variables in the system. These values can be derived as the predictions from a linear regression of each endogenous regressor on all exogenous variables in the system or, more succinctly, as the projection of each regressor through the projection matrix of all exogenous variables onto the regressors. Designating the set of all exogenous variables as $\mathbf{X}$ results in

$$\widehat{\mathbf{z}}_i = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{z}_i \quad \text{for each } i$$

Taken collectively, these $\widehat{\mathbf{Z}}$ contain the instrumented values for all the regressors. They take on the actual values for the exogenous variables and first-stage predictions for the endogenous variables. Given these instrumented variables, a generalized least squares (GLS) or Aitken (1935) estimator can be formed for the parameters of the system

$$\widehat{\mathbf{B}} = \left\{\widehat{\mathbf{Z}}'(\mathbf{\Sigma}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}}\right\}^{-1} \widehat{\mathbf{Z}}'(\mathbf{\Sigma}^{-1} \otimes \mathbf{I})\mathbf{y}$$

All that remains is to obtain a consistent estimator for $\mathbf{\Sigma}$. This estimate can be formed from the residuals of 2SLS estimates of each equation in the system. Alternately, and identically, the residuals can be computed from the estimates formed by taking $\mathbf{\Sigma}$ to be an identity matrix. This maintains the full system of coefficients and allows constraints to be applied when the residuals are computed.

If we take $\mathbf{E}$ to be the matrix of residuals from these estimates, a consistent estimate of $\mathbf{\Sigma}$ is

$$\widehat{\mathbf{\Sigma}} = \frac{\mathbf{E}'\mathbf{E}}{n}$$

where n is the number of observations in the sample. An alternative divisor for this estimate can be obtained with the `dfk` option as outlined under options.

With the estimate of $\widehat{\mathbf{\Sigma}}$ placed into the GLS estimating equation,

$$\widehat{\mathbf{B}} = \left\{\widehat{\mathbf{Z}}'(\widehat{\mathbf{\Sigma}}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}}\right\}^{-1} \widehat{\mathbf{Z}}'(\widehat{\mathbf{\Sigma}}^{-1} \otimes \mathbf{I})\mathbf{y}$$

is the 3SLS estimates of the system parameters.

The asymptotic variance–covariance matrix of the estimator is just the standard formulation for a GLS estimator

$$\mathbf{V}_{\widehat{\mathbf{B}}} = \left\{\widehat{\mathbf{Z}}'(\widehat{\mathbf{\Sigma}}^{-1} \otimes \mathbf{I})\widehat{\mathbf{Z}}\right\}^{-1}$$

Iterated 3SLS estimates can be obtained by computing the residuals from the three-stage parameter estimates, using these to formulate a new $\widehat{\mathbf{\Sigma}}$, and recomputing the parameter estimates. This process is repeated until the estimates $\widehat{\mathbf{B}}$ converge—if they converge. Convergence is not guaranteed. When estimating a system by SURE, these iterated estimates will be the maximum likelihood estimates for the system. The iterated solution can also be used to produce estimates that are invariant to choice of system and restriction parameterization for many linear systems under full 3SLS.

The exposition above follows the parallel developments in Greene (2012) and Davidson and MacKinnon (1993).

Henri Theil (1924–2000) was born in Amsterdam and awarded a PhD in 1951 by the University of Amsterdam. He researched and taught econometric theory, statistics, microeconomics, macroeconomic modeling, and economic forecasting, and policy at (what is now) Erasmus University Rotterdam, the University of Chicago, and the University of Florida. Theil's many specific contributions include work on 2SLS and 3SLS, inequality and concentration, and consumer demand.

Title

reg3 postestimation — Postestimation tools for reg3

Description

The following postestimation commands are available after `reg3`:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
*`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

*`estat ic` is not appropriate after `reg3, 2sls`.

See the corresponding entries in the *Base Reference Manual* for details.

Syntax for predict

`predict` [*type*] *newvar* [*if*] [*in*] [`, equation(`*eqno*[`,`*eqno*]`)` *statistic*]

statistic	Description
Main	
`xb`	linear prediction; the default
`stdp`	standard error of the linear prediction
`residuals`	residuals
`difference`	difference between the linear predictions of two equations
`stddp`	standard error of the difference in linear predictions

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`equation(`*eqno*`[ ,`*eqno*`])` specifies to which equation you are referring.

`equation()` is filled in with one *eqno* for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

`difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

`xb`, the default, calculates the linear prediction (fitted values)—the prediction of $\mathbf{x}_j\mathbf{b}$ for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.

`difference` calculates the difference between the linear predictions of two equations in the system. With `equation(#1,#2)`, `difference` computes the prediction of `equation(#1)` minus the prediction of `equation(#2)`.

`stddp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions $(\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b})$ between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [R] **predict**.

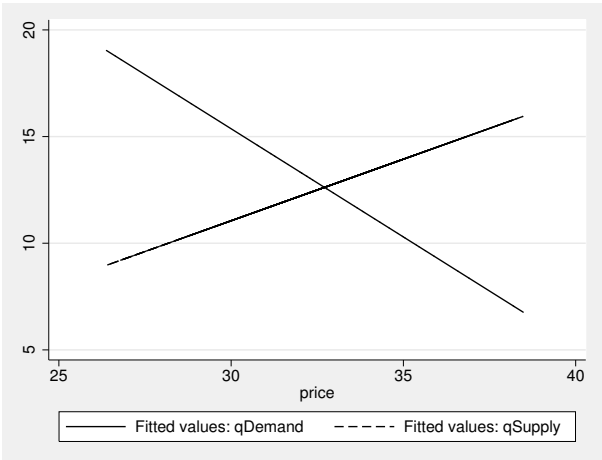
Remarks

▷ Example 1

In example 2 of [R] **reg3**, we fit a simple supply-and-demand model. Here we obtain the fitted supply and demand curves assuming that the exogenous regressors equal their sample means. We first `replace` each of the three exogenous regressors with their sample means, then we call `predict` to obtain the predictions.

```
. use http://www.stata-press.com/data/r12/supDem
. global demand "(qDemand: quantity price pcompete income)"
. global supply "(qSupply: quantity price praw)"
. reg3 $demand $supply, endog(price)
  (output omitted)
. summarize pcompete, meanonly
. replace pcompete = r(mean)
(49 real changes made)
```

```
. summarize income, meanonly
. replace income = r(mean)
(49 real changes made)
. summarize praw, meanonly
. replace praw = r(mean)
(49 real changes made)
. predict demand, equation(qDemand)
(option xb assumed; fitted values)
. predict supply, equation(qSupply)
(option xb assumed; fitted values)
. graph twoway line demand price, sort || line supply price
```



As we would expect based on economic theory, the demand curve slopes downward while the supply curve slopes upward. With the exogenous variables at their mean levels, the equilibrium price and quantity are slightly less than 33 and 13, respectively.

◁

Methods and formulas

All postestimation commands listed above are implemented as ado-files.

The computational formulas for the statistics produced by `predict` can be found in [R] **predict** and [R] **regress postestimation**.

Title

regress — Linear regression

Syntax

```
regress depvar [indepvars] [if] [in] [weight] [, options]
```

options	Description
Model	
noconstant	suppress constant term
hascons	has user-supplied constant
tsscons	compute total sum of squares with constant; seldom used
SE/Robust	
vce(*vcetype*)	*vcetype* may be ols, robust, cluster *clustvar*, bootstrap, jackknife, hc2, or hc3
Reporting	
level(#)	set confidence level; default is level(95)
beta	report standardized beta coefficients
eform(*string*)	report exponentiated coefficients and label as *string*
depname(*varname*)	substitute dependent variable name; programmer's option
display_options	control column formats, row spacing, line width, and display of omitted variables and base and empty cells
noheader	suppress output header
notable	suppress coefficient table
plus	make table extendable
mse1	force mean squared error to 1
coeflegend	display legend instead of statistics

indepvars may contain factor variables; see [U] **11.4.3 Factor variables**.

depvar and *indepvars* may contain time-series operators; see [U] **11.4.4 Time-series varlists**.

bootstrap, by, fracpoly, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] **11.1.10 Prefix commands**.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] **mi estimate**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

aweights are not allowed with the jackknife prefix; see [R] **jackknife**.

hascons, tsscons, vce(), beta, noheader, notable, plus, depname(), mse1, and weights are not allowed with the svy prefix; see [SVY] **svy**.

aweights, fweights, iweights, and pweights are allowed; see [U] **11.1.6 weight**.

noheader, notable, plus, mse1, and coeflegend do not appear in the dialog box.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Linear models and related > Linear regression

Description

`regress` fits a model of *depvar* on *indepvars* using linear regression.

Here is a short list of other regression commands that may be of interest. See [I] **estimation commands** for a complete list.

Command	Entry	Description
`areg`	[R] **areg**	an easier way to fit regressions with many dummy variables
`arch`	[TS] **arch**	regression models with ARCH errors
`arima`	[TS] **arima**	ARIMA models
`boxcox`	[R] **boxcox**	Box–Cox regression models
`cnsreg`	[R] **cnsreg**	constrained linear regression
`eivreg`	[R] **eivreg**	errors-in-variables regression
`frontier`	[R] **frontier**	stochastic frontier models
`gmm`	[R] **gmm**	generalized method of moments estimation
`heckman`	[R] **heckman**	Heckman selection model
`intreg`	[R] **intreg**	interval regression
`ivregress`	[R] **ivregress**	single-equation instrumental-variables regression
`ivtobit`	[R] **ivtobit**	tobit regression with endogenous variables
`newey`	[TS] **newey**	regression with Newey–West standard errors
`nl`	[R] **nl**	nonlinear least-squares estimation
`nlsur`	[R] **nlsur**	estimation of nonlinear systems of equations
`qreg`	[R] **qreg**	quantile (including median) regression
`reg3`	[R] **reg3**	three-stage least-squares (3SLS) regression
`rreg`	[R] **rreg**	a type of robust regression
`sureg`	[R] **sureg**	seemingly unrelated regression
`tobit`	[R] **tobit**	tobit regression
`treatreg`	[R] **treatreg**	treatment-effects model
`truncreg`	[R] **truncreg**	truncated regression
`xtabond`	[XT] **xtabond**	Arellano–Bond linear dynamic panel-data estimation
`xtdpd`	[XT] **xtdpd**	linear dynamic panel-data estimation
`xtfrontier`	[XT] **xtfrontier**	panel-data stochastic frontier models
`xtgls`	[XT] **xtgls**	panel-data GLS models
`xthtaylor`	[XT] **xthtaylor**	Hausman–Taylor estimator for error-components models
`xtintreg`	[XT] **xtintreg**	panel-data interval regression models
`xtivreg`	[XT] **xtivreg**	panel-data instrumental-variables (2SLS) regression
`xtpcse`	[XT] **xtpcse**	linear regression with panel-corrected standard errors
`xtreg`	[XT] **xtreg**	fixed- and random-effects linear models
`xtregar`	[XT] **xtregar**	fixed- and random-effects linear models with an AR(1) disturbance
`xttobit`	[XT] **xttobit**	panel-data tobit models
	[SEM] *Stata Structural Equation Modeling Reference Manual*	

Options

Model

`noconstant`; see [R] **estimation options**.

`hascons` indicates that a user-defined constant or its equivalent is specified among the independent variables in *indepvars*. Some caution is recommended when specifying this option, as resulting estimates may not be as accurate as they otherwise would be. Use of this option requires "sweeping" the constant last, so the moment matrix must be accumulated in absolute rather than deviation form. This option may be safely specified when the means of the dependent and independent variables are all reasonable and there is not much collinearity between the independent variables. The best procedure is to view `hascons` as a reporting option—estimate with and without `hascons` and verify that the coefficients and standard errors of the variables not affected by the identity of the constant are unchanged.

`tsscons` forces the total sum of squares to be computed as though the model has a constant, that is, as deviations from the mean of the dependent variable. This is a rarely used option that has an effect only when specified with `noconstant`. It affects the total sum of squares and all results derived from the total sum of squares.

SE/Robust

`vce(`*vcetype*`)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory, that are robust to some kinds of misspecification, that allow for intragroup correlation, and that use bootstrap or jackknife methods; see [R] ***vce_option***.

`vce(ols)`, the default, uses the standard variance estimator for ordinary least-squares regression.

`regress` also allows the following:

`vce(hc2)` and `vce(hc3)` specify an alternative bias correction for the robust variance calculation. `vce(hc2)` and `vce(hc3)` may not be specified with `svy` prefix. In the unclustered case, `vce(robust)` uses $\widehat{\sigma}_j^2 = \{n/(n-k)\}u_j^2$ as an estimate of the variance of the jth observation, where u_j is the calculated residual and $n/(n-k)$ is included to improve the overall estimate's small-sample properties.

`vce(hc2)` instead uses $u_j^2/(1-h_{jj})$ as the observation's variance estimate, where h_{jj} is the diagonal element of the hat (projection) matrix. This estimate is unbiased if the model really is homoskedastic. `vce(hc2)` tends to produce slightly more conservative confidence intervals.

`vce(hc3)` uses $u_j^2/(1-h_{jj})^2$ as suggested by Davidson and MacKinnon (1993), who report that this method tends to produce better results when the model really is heteroskedastic. `vce(hc3)` produces confidence intervals that tend to be even more conservative.

See Davidson and MacKinnon (1993, 554–556) and Angrist and Pischke (2009, 294–308) for more discussion on these two bias corrections.

Reporting

`level(#)`; see [R] **estimation options**.

`beta` asks that standardized beta coefficients be reported instead of confidence intervals. The beta coefficients are the regression coefficients obtained by first standardizing all variables to have a mean of 0 and a standard deviation of 1. `beta` may not be specified with `vce(cluster` *clustvar*`)` or the `svy` prefix.

`eform(`*string*`)` is used only in programs and ado-files that use `regress` to fit models other than linear regression. `eform()` specifies that the coefficient table be displayed in exponentiated form as defined in [R] **maximize** and that *string* be used to label the exponentiated coefficients in the table.

`depname(`*varname*`)` is used only in programs and ado-files that use `regress` to fit models other than linear regression. `depname()` may be specified only at estimation time. *varname* is recorded as the identity of the dependent variable, even though the estimates are calculated using *depvar*. This method affects the labeling of the output—not the results calculated—but could affect subsequent calculations made by `predict`, where the residual would be calculated as deviations from *varname* rather than *depvar*. `depname()` is most typically used when *depvar* is a temporary variable (see [P] **macro**) used as a proxy for *varname*.

`depname()` is not allowed with the `svy` prefix.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

The following options are available with `regress` but are not shown in the dialog box:

`noheader` suppresses the display of the ANOVA table and summary statistics at the top of the output; only the coefficient table is displayed. This option is often used in programs and ado-files.

`notable` suppresses display of the coefficient table.

`plus` specifies that the output table be made extendable. This option is often used in programs and ado-files.

`mse1` is used only in programs and ado-files that use `regress` to fit models other than linear regression and is not allowed with the `svy` prefix. `mse1` sets the mean squared error to `1`, forcing the variance–covariance matrix of the estimators to be $(\mathbf{X}'\mathbf{D}\mathbf{X})^{-1}$ (see *Methods and formulas* below) and affecting calculated standard errors. Degrees of freedom for t statistics are calculated as n rather than $n-k$.

`coeflegend`; see [R] **estimation options**.

Remarks

Remarks are presented under the following headings:

Ordinary least squares
Treatment of the constant
Robust standard errors
Weighted regression
Instrumental variables and two-stage least-squares regression

`regress` performs linear regression, including ordinary least squares and weighted least squares. For a general discussion of linear regression, see Draper and Smith (1998), Greene (2012), or Kmenta (1997).

See Wooldridge (2009) for an excellent treatment of estimation, inference, interpretation, and specification testing in linear regression models. This presentation stands out for its clarification of the statistical issues, as opposed to the algebraic issues. See Wooldridge (2010, chap. 4) for a more advanced discussion along the same lines.

See Hamilton (2009, chap. 6) and Cameron and Trivedi (2010, chap. 3) for an introduction to linear regression using Stata. Dohoo, Martin, and Stryhn (2010) discuss linear regression using examples from epidemiology, and Stata datasets and do-files used in the text are available. Cameron and Trivedi (2010) discuss linear regression using econometric examples with Stata.

Chatterjee and Hadi (2006) explain regression analysis by using examples containing typical problems that you might encounter when performing exploratory data analysis. We also recommend Weisberg (2005), who emphasizes the importance of the assumptions of linear regression and problems resulting from these assumptions. Angrist and Pischke (2009) approach regression as a tool for exploring relationships, estimating treatment effects, and providing answers to public policy questions. For a discussion of model-selection techniques and exploratory data analysis, see Mosteller and Tukey (1977). For a mathematically rigorous treatment, see Peracchi (2001, chap. 6). Finally, see Plackett (1972) if you are interested in the history of regression. Least squares, which dates back to the 1790s, was discovered independently by Legendre and Gauss.

Ordinary least squares

▷ Example 1

Suppose that we have data on the mileage rating and weight of 74 automobiles. The variables in our data are `mpg`, `weight`, and `foreign`. The last variable assumes the value 1 for foreign and 0 for domestic automobiles. We wish to fit the model

$$\texttt{mpg} = \beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{weight}^2 + \beta_3\texttt{foreign} + \epsilon$$

We include `c.weight#c.weight` in our model for the weight-squared term (see [U] **11.4.3 Factor variables**):

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight c.weight#c.weight foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  3,    70) =   52.25
       Model |  1689.15372     3  563.05124              Prob > F      =  0.0000
    Residual |   754.30574    70  10.7757963            R-squared     =  0.6913
-------------+------------------------------           Adj R-squared =  0.6781
       Total |  2443.45946    73  33.4720474            Root MSE      =  3.2827

------------------------------------------------------------------------------
         mpg |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]

------------------------------------------------------------------------------
```

◁

`regress` produces a variety of summary statistics along with the table of regression coefficients. At the upper left, `regress` reports an analysis-of-variance (ANOVA) table. The column headings `SS`, `df`, and `MS` stand for "sum of squares", "degrees of freedom", and "mean square", respectively. In the previous example, the total sum of squares is 2,443.5: 1,689.2 accounted for by the model and 754.3 left unexplained. Because the regression included a constant, the total sum reflects the sum after removal of means, as does the sum of squares due to the model. The table also reveals that there are 73 total degrees of freedom (counted as 74 observations less 1 for the mean removal), of which 3 are consumed by the model, leaving 70 for the residual.

To the right of the ANOVA table are presented other summary statistics. The F statistic associated with the ANOVA table is 52.25. The statistic has 3 numerator and 70 denominator degrees of freedom. The F statistic tests the hypothesis that all coefficients *excluding the constant* are zero. The chance of observing an F statistic that large or larger is reported as 0.0000, which is Stata's way of indicating a number smaller than 0.00005. The R-squared (R^2) for the regression is 0.6913, and the R-squared adjusted for degrees of freedom (R^2_a) is 0.6781. The root mean squared error, labeled `Root MSE`, is 3.2827. It is the square root of the mean squared error reported for the residual in the ANOVA table.

Finally, Stata produces a table of the estimated coefficients. The first line of the table indicates that the left-hand-side variable is `mpg`. Thereafter follow the four estimated coefficients. Our fitted model is

$$\texttt{mpg\_hat} = 56.54 - 0.0166\,\texttt{weight} + 1.59 \times 10^{-6}\,\texttt{c.weight\#c.weight} - 2.20\,\texttt{foreign}$$

Reported to the right of the coefficients in the output are the standard errors. For instance, the standard error for the coefficient on `weight` is 0.0039692. The corresponding t statistic is -4.18, which has a two-sided significance level of 0.000. This number indicates that the significance is less than 0.0005. The 95% confidence interval for the coefficient is $[-0.024, -0.009]$.

▷ Example 2

`regress` shares the features of all estimation commands. Among other things, this means that after running a regression, we can use `test` to test hypotheses about the coefficients, `estat vce` to examine the covariance matrix of the estimators, and `predict` to obtain predicted values, residuals, and influence statistics. See [U] **20 Estimation and postestimation commands**. Options that affect how estimates are displayed, such as `beta` or `level()`, can be used when replaying results.

Suppose that we meant to specify the `beta` option to obtain beta coefficients (regression coefficients normalized by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable). Even though we forgot, we can specify the option now:

```
. regress, beta
```

Source	SS	df	MS		
Model	1689.15372	3	563.05124	Number of obs	= 74
Residual	754.30574	70	10.7757963	F(3, 70)	= 52.25
				Prob > F	= 0.0000
				R-squared	= 0.6913
				Adj R-squared	= 0.6781
Total	2443.45946	73	33.4720474	Root MSE	= 3.2827

mpg	Coef.	Std. Err.	t	P>|t|	Beta
weight	-.0165729	.0039692	-4.18	0.000	-2.226321
c.weight# c.weight	1.59e-06	6.25e-07	2.55	0.013	1.32654
foreign	-2.2035	1.059246	-2.08	0.041	-.17527
_cons	56.53884	6.197383	9.12	0.000	.

◁

Treatment of the constant

By default, regress includes an intercept (constant) term in the model. The noconstant option suppresses it, and the hascons option tells regress that the model already has one.

▷ Example 3

We wish to fit a regression of the weight of an automobile against its length, and we wish to impose the constraint that the weight is zero when the length is zero.

If we simply type regress weight length, we are fitting the model

$$\texttt{weight} = \beta_0 + \beta_1\,\texttt{length} + \epsilon$$

Here a length of zero corresponds to a weight of β_0. We want to force β_0 to be zero or, equivalently, estimate an equation that does not include an intercept:

$$\texttt{weight} = \beta_1\,\texttt{length} + \epsilon$$

We do this by specifying the noconstant option:

```
. regress weight length, noconstant
```

Source	SS	df	MS	Number of obs =	74
				F(1, 73) =	3450.13
Model	703869302	1	703869302	Prob > F =	0.0000
Residual	14892897.8	73	204012.299	R-squared =	0.9793
				Adj R-squared =	0.9790
Total	718762200	74	9713002.7	Root MSE =	451.68

weight	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
length	16.29829	.2774752	58.74	0.000	15.74528	16.8513

In our data, length is measured in inches and weight in pounds. We discover that each inch of length adds 16 pounds to the weight.

◁

Sometimes there is no need for Stata to include a constant term in the model. Most commonly, this occurs when the model contains a set of mutually exclusive indicator variables. hascons is a variation of the noconstant option—it tells Stata not to add a constant to the regression because the regression specification already has one, either directly or indirectly.

For instance, we now refit our model of weight as a function of length and include separate constants for foreign and domestic cars by specifying bn.foreign. bn.foreign is factor-variable notation for "no base for foreign" or "include all levels of variable foreign in the model"; see [U] **11.4.3 Factor variables**.

```
. regress weight length bn.foreign, hascons
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =  316.54
       Model |  39647744.7     2  19823872.3            Prob > F      =  0.0000
    Residual |   4446433.7    71  62625.8268            R-squared     =  0.8992
-------------+------------------------------           Adj R-squared =  0.8963
       Total |  44094178.4    73  604029.841            Root MSE      =  250.25

------------------------------------------------------------------------------
      weight |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      length |   31.44455   1.601234    19.64   0.000     28.25178    34.63732
             |
     foreign |
           0 |   -2850.25   315.9691    -9.02   0.000    -3480.274   -2220.225
           1 |  -2983.927   275.1041   -10.85   0.000    -3532.469   -2435.385
------------------------------------------------------------------------------
```

❑ Technical note

There is a subtle distinction between the `hascons` and `noconstant` options. We can most easily reveal it by refitting the last regression, specifying `noconstant` rather than `hascons`:

```
. regress weight length bn.foreign, noconstant
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  3,    71) = 3802.03
       Model |  714315766     3   238105255            Prob > F      =  0.0000
    Residual |   4446433.7    71  62625.8268            R-squared     =  0.9938
-------------+------------------------------           Adj R-squared =  0.9936
       Total |  718762200    74   9713002.7            Root MSE      =  250.25

------------------------------------------------------------------------------
      weight |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      length |   31.44455   1.601234    19.64   0.000     28.25178    34.63732
             |
     foreign |
           0 |   -2850.25   315.9691    -9.02   0.000    -3480.274   -2220.225
           1 |  -2983.927   275.1041   -10.85   0.000    -3532.469   -2435.385
------------------------------------------------------------------------------
```

Comparing this output with that produced by the previous `regress` command, we see that they are almost, but not quite, identical. The parameter estimates and their associated statistics—the second half of the output—are identical. The overall summary statistics and the ANOVA table—the first half of the output—are different, however.

In the first case, the R^2 is shown as 0.8992; here it is shown as 0.9938. In the first case, the F statistic is 316.54; now it is 3,802.03. The numerator degrees of freedom are different as well. In the first case, the numerator degrees of freedom are 2; now they are 3. Which is correct?

Both are. Specifying the `hascons` option causes `regress` to adjust the ANOVA table and its associated statistics for the explanatory power of the constant. The regression in effect has a constant; it is just written in such a way that a separate constant is unnecessary. No such adjustment is made with the `noconstant` option.

❑

❑ Technical note

When the hascons option is specified, regress checks to make sure that the model does in fact have a constant term. If regress cannot find a constant term, it automatically adds one. Fitting a model of weight on length and specifying the hascons option, we obtain

```
. regress weight length, hascons
(note: hascons false)
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =  613.27
       Model |  39461306.8     1  39461306.8            Prob > F      =  0.0000
    Residual |  4632871.55    72  64345.4382            R-squared     =  0.8949
-------------+------------------------------           Adj R-squared =  0.8935
       Total |  44094178.4    73  604029.841            Root MSE      =  253.66

------------------------------------------------------------------------------
      weight |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
      length |   33.01988   1.333364    24.76   0.000     30.36187    35.67789
       _cons |  -3186.047   252.3113   -12.63   0.000     -3689.02   -2683.073
------------------------------------------------------------------------------
```

Even though we specified hascons, regress included a constant, anyway. It also added a note to our output: "note: hascons false".

❑

❑ Technical note

Even if the model specification effectively includes a constant term, we need not specify the hascons option. regress is always on the lookout for collinear variables and omits them from the model. For instance,

```
. regress weight length bn.foreign
note: 1.foreign omitted because of collinearity
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  2,    71) =  316.54
       Model |  39647744.7     2  19823872.3            Prob > F      =  0.0000
    Residual |  4446433.7     71  62625.8268            R-squared     =  0.8992
-------------+------------------------------           Adj R-squared =  0.8963
       Total |  44094178.4    73  604029.841            Root MSE      =  250.25

------------------------------------------------------------------------------

Robust standard errors

regress with the vce(robust) option substitutes a robust variance matrix calculation for the conventional calculation, or if vce(cluster *clustvar*) is specified, allows relaxing the assumption of independence within groups. How this method works is explained in [U] **20.20 Obtaining robust variance estimates**. Below we show how well this approach works.

▷ Example 4

Specifying the vce(robust) option is equivalent to requesting White-corrected standard errors in the presence of heteroskedasticity. We use the automobile data and, in the process of looking at the energy efficiency of cars, analyze a variable with considerable heteroskedasticity.

We will examine the amount of energy—measured in gallons of gasoline—that the cars in the data need to move 1,000 pounds of their weight 100 miles. We are going to examine the relative efficiency of foreign and domestic cars.

```
. gen gpmw = ((1/mpg)/weight)*100*1000
. summarize gpmw
    Variable |      Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
        gpmw |       74    1.682184    .2426311    1.09553    2.30521
```

In these data, the engines consume between 1.10 and 2.31 gallons of gas to move 1,000 pounds of the car's weight 100 miles. If we ran a regression with conventional standard errors of gpmw on foreign, we would obtain

```
. regress gpmw foreign
      Source |       SS       df       MS              Number of obs =      74
-------------+------------------------------           F(  1,    72) =   20.07
       Model |  .936705572     1  .936705572            Prob > F      =  0.0000
    Residual |  3.36079459    72  .046677703            R-squared     =  0.2180
-------------+------------------------------           Adj R-squared =  0.2071
       Total |  4.29750017    73  .058869865            Root MSE      =  .21605

------------------------------------------------------------------------------
        gpmw |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     foreign |   .2461526   .0549487     4.48   0.000     .1366143    .3556909
       _cons |   1.609004   .0299608    53.70   0.000     1.549278     1.66873
------------------------------------------------------------------------------
```

regress with the vce(robust) option, on the other hand, reports

```
. regress gpmw foreign, vce(robust)
Linear regression                               Number of obs =      74
                                                F(  1,    72) =   13.13
                                                Prob > F      =  0.0005
                                                R-squared     =  0.2180
                                                Root MSE      =  .21605

------------------------------------------------------------------------------
             |               Robust
        gpmw |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     foreign |   .2461526   .0679238     3.62   0.001     .1107489    .3815563
       _cons |   1.609004   .0234535    68.60   0.000      1.56225    1.655758
------------------------------------------------------------------------------
```

The point estimates are the same (foreign cars need one-quarter gallon more gas), but the standard errors differ by roughly 20%. Conventional regression reports the 95% confidence interval as $[0.14, 0.36]$, whereas the robust standard errors make the interval $[0.11, 0.38]$.

Which is right? Notice that `gpmw` is a variable with considerable heteroskedasticity:

```
. tabulate foreign, summarize(gpmw)
```

Car type	Summary of gpmw Mean	Std. Dev.	Freq.
Domestic	1.6090039	.16845182	52
Foreign	1.8551565	.30186861	22
Total	1.6821844	.24263113	74

Thus here we favor the robust standard errors. In [U] **20.20 Obtaining robust variance estimates**, we show another example using linear regression where it makes little difference whether we specify `vce(robust)`. The linear-regression assumptions were true, and we obtained nearly linear-regression results. The advantage of the robust estimate is that in neither case did we have to check assumptions.

◁

❑ Technical note

`regress` purposefully suppresses displaying the ANOVA table when `vce(robust)` is specified, as it is no longer appropriate in a statistical sense, even though, mechanically, the numbers would be unchanged. That is, sums of squares remain unchanged, but the meaning of those sums is no longer relevant. The F statistic, for instance, is no longer based on sums of squares; it becomes a Wald test based on the robustly estimated variance matrix. Nevertheless, `regress` continues to report the R^2 and the root MSE even though both numbers are based on sums of squares and are, strictly speaking, irrelevant. In this, the root MSE is more in violation of the spirit of the robust estimator than is R^2. As a goodness-of-fit statistic, R^2 is still fine; just do not use it in formulas to obtain F statistics because those formulas no longer apply. The root MSE is valid in a literal sense—it is the square root of the mean squared error, but it is no longer an estimate of σ because there is no single σ; the variance of the residual varies observation by observation.

❑

▷ Example 5

The `vce(hc2)` and `vce(hc3)` options modify the robust variance calculation. In the context of linear regression without clustering, the idea behind the robust calculation is somehow to measure σ_j^2, the variance of the residual associated with the jth observation, and then to use that estimate to improve the estimated variance of $\widehat{\boldsymbol{\beta}}$. Because residuals have (theoretically and practically) mean 0, one estimate of σ_j^2 is the observation's squared residual itself—u_j^2. A finite-sample correction could improve that by multiplying u_j^2 by $n/(n-k)$, and, as a matter of fact, `vce(robust)` uses $\{n/(n-k)\}u_j^2$ as its estimate of the residual's variance.

`vce(hc2)` and `vce(hc3)` use alternative estimators of the observation-specific variances. For instance, if the residuals are homoskedastic, we can show that the expected value of u_j^2 is $\sigma^2(1-h_{jj})$, where h_{jj} is the jth diagonal element of the projection (hat) matrix. h_{jj} has average value k/n, so $1-h_{jj}$ has average value $1-k/n = (n-k)/n$. Thus the default robust estimator $\widehat{\sigma}_j = \{n/(n-k)\}u_j^2$ amounts to dividing u_j^2 by the average of the expectation.

vce(hc2) divides u_j^2 by $1 - h_{jj}$ itself, so it should yield better estimates if the residuals really are homoskedastic. vce(hc3) divides u_j^2 by $(1 - h_{jj})^2$ and has no such clean interpretation. Davidson and MacKinnon (1993) show that $u_j^2/(1 - h_{jj})^2$ approximates a more complicated estimator that they obtain by jackknifing (MacKinnon and White 1985). Angrist and Pischke (2009) also illustrate the relative merits of these adjustments.

Here are the results of refitting our efficiency model using vce(hc2) and vce(hc3):

```
. regress gpmw foreign, vce(hc2)
Linear regression                               Number of obs =      74
                                                F(  1,    72) =   12.93
                                                Prob > F      =  0.0006
                                                R-squared     =  0.2180
                                                Root MSE      =  .21605
```

◁

▷ Example 6

The vce(cluster *clustvar*) option relaxes the assumption of independence. Below we have 28,534 observations on 4,711 women aged 14–46 years. Data were collected on these women between 1968 and 1988. We are going to fit a classic earnings model, and we begin by ignoring that each woman appears an average of 6.056 times in the data.

```
. use http://www.stata-press.com/data/r12/regsmpl, clear
(NLS Women 14-26 in 1968)
. regress ln_wage age c.age#c.age tenure
      Source |       SS       df       MS              Number of obs =   28101
-------------+------------------------------           F(  3, 28097) = 1842.45
       Model |  1054.52501     3  351.508335            Prob > F      =  0.0000
    Residual |  5360.43962 28097  .190783344            R-squared     =  0.1644
-------------+------------------------------           Adj R-squared =  0.1643
       Total |  6414.96462 28100  .228290556            Root MSE      =  .43679

------------------------------------------------------------------------------
```

The number of observations in our model is 28,101 because Stata drops observations that have a missing value for one or more of the variables in the model. We can be reasonably certain that the standard errors reported above are meaningless. Without a doubt, a woman with higher-than-average wages in one year typically has higher-than-average wages in other years, and so the residuals are not independent. One way to deal with this would be to fit a random-effects model—and we are going to do that—but first we fit the model using `regress` specifying `vce(cluster id)`, which treats only observations with different person `id`s as truly independent:

```
. regress ln_wage age c.age#c.age tenure, vce(cluster id)
Linear regression                               Number of obs =   28101
                                                F(  3,  4698) =  748.82
                                                Prob > F      =  0.0000
                                                R-squared     =  0.1644
                                                Root MSE      =  .43679

                                  (Std. Err. adjusted for 4699 clusters in idcode)
------------------------------------------------------------------------------
             |               Robust
     ln_wage |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
         age |   .0752172   .0045711    16.45   0.000     .0662557    .0841788
             |
 c.age#c.age |  -.0010851   .0000778   -13.94   0.000    -.0012377   -.0009325

       _cons |   .3339821   .0641918     5.20   0.000      .208136    .4598282
------------------------------------------------------------------------------
```

For comparison, we focus on the tenure coefficient, which in economics jargon can be interpreted as the rate of return for keeping your job. The 95% confidence interval we previously estimated—an interval we do not believe—is $[0.038, 0.041]$. The robust interval is twice as wide, being $[0.036, 0.042]$.

As we said, one correct way to fit this model is by random-effects regression. Here is the random-effects result:

```
. xtreg ln_wage age c.age#c.age tenure, re
Random-effects GLS regression                   Number of obs      =     28101
Group variable: idcode                          Number of groups   =      4699

R-sq:  within  = 0.1370                         Obs per group: min =         1
       between = 0.2154                                        avg =       6.0
       overall = 0.1608                                        max =        15

Random effects u_i ~ Gaussian                   Wald chi2(3)       =   4717.05
corr(u_i, X)       = 0 (assumed)                Prob > chi2        =    0.0000

------------------------------------------------------------------------------

-------------+----------------------------------------------------------------
         age |   .0568296   .0026958    21.08   0.000     .0515459    .0621132
             |
 c.age#c.age |  -.0007566   .0000447   -16.93   0.000    -.0008441   -.000669
             |
      tenure |   .0260135   .0007477    34.79   0.000     .0245481    .0274789
       _cons |   .6136792   .0394611    15.55   0.000     .5363368    .6910216
-------------+----------------------------------------------------------------
     sigma_u |  .33542449
     sigma_e |  .29674679
         rho |  .56095413   (fraction of variance due to u_i)
------------------------------------------------------------------------------
```

Robust regression estimated the 95% interval $[0.036, 0.042]$, and `xtreg` (see [XT] **xtreg**) estimates $[0.025, 0.027]$. Which is better? The random-effects regression estimator assumes a lot. We can check some of these assumptions by performing a Hausman test. Using `estimates` (see [R] **estimates store**), we save the random-effects estimation results, and then we run the required fixed-effects regression to perform the test.

```

```

The Hausman test casts grave suspicions on the random-effects model we just fit, so we should be careful in interpreting those results.

Meanwhile, our robust regression results still stand, as long as we are careful about the interpretation. The correct interpretation is that, if the data collection were repeated (on women sampled the same way as in the original sample), and if we were to refit the model, 95% of the time we would expect the estimated coefficient on tenure to be in the range $[0.036, 0.042]$.

Even with robust regression, we must be careful about going beyond that statement. Here the Hausman test is probably picking up something that differs within and between person, which would cast doubt on our robust regression model in terms of interpreting $[0.036, 0.042]$ to contain the rate of return for keeping a job, economywide, for all women, without exception. ◁

Weighted regression

`regress` can perform weighted and unweighted regression. We indicate the weight by specifying the [*weight*] qualifier. By default, `regress` assumes analytic weights; see the technical note below.

▷ Example 7

We have census data recording the death rate (`drate`) and median age (`medage`) for each state. The data also record the region of the country in which each state is located and the overall population of the state:

```
. use http://www.stata-press.com/data/r12/census9
(1980 Census data by state)
. describe
Contains data from http://www.stata-press.com/data/r12/census9.dta

drate           float  %9.0g                  Death Rate
pop             long   %12.0gc                Population
medage          float  %9.2f                  Median age
region          byte   %-8.0g      cenreg      Census region
-------------------------------------------------------------------------------
Sorted by:
```

We can use factor variables to include dummy variables for region. Because the variables in the regression reflect means rather than individual observations, the appropriate method of estimation is analytically weighted least squares (Davidson and MacKinnon 2004, 261–262), where the weight is total population:

```
. regress drate medage i.region [w=pop]
(analytic weights assumed)
(sum of wgt is   2.2591e+08)
```

Source	SS	df	MS	Number of obs =	50

To weight the regression by population, we added the qualifier `[w=pop]` to the end of the `regress` command. Our qualifier was vague (we did not say `[aweight=pop]`), but unless told otherwise, Stata assumes analytic weights for `regress`. Stata informed us that the sum of the weight is 2.2591×10^8; there were approximately 226 million people residing in the United States according to our 1980 data. ◁

❑ Technical note

Once we fit a weighted regression, we can obtain the appropriately weighted variance–covariance matrix of the estimators using `estat vce` and perform appropriately weighted hypothesis tests using `test`.

In the weighted regression in the previous example, we see that `4.region` is statistically significant but that `2.region` and `3.region` are not. We use `test` to test the joint significance of the region variables:

```
. test 2.region 3.region 4.region
 ( 1)  2.region = 0
 ( 2)  3.region = 0
 ( 3)  4.region = 0
       F(  3,    45) =    9.84
            Prob > F =    0.0000
```

The results indicate that the region variables are jointly significant.

❑

`regress` also accepts frequency weights (`fweight`s). Frequency weights are appropriate when the data do not reflect cell means, but instead represent replicated observations. Specifying `aweight`s or `fweight`s will not change the parameter estimates, but it will change the corresponding significance levels.

For instance, if we specified [fweight=pop] in the weighted regression example above—which would be statistically incorrect—Stata would treat the data as if the data represented 226 million independent observations on death rates and median age. The data most certainly do not represent that—they represent 50 observations on state averages.

With aweights, Stata treats the number of observations on the process as the number of observations in the data. When we specify fweights, Stata treats the number of observations as if it were equal to the sum of the weights; see *Methods and formulas* below.

❑ Technical note

A popular request on the help line is to describe the effect of specifying [aweight=*exp*] with regress in terms of transformation of the dependent and independent variables. The mechanical answer is that typing

```
. regress y x1 x2 [aweight=n]
```

is equivalent to fitting the model

$$y_j\sqrt{n_j} = \beta_0\sqrt{n_j} + \beta_1 x_{1j}\sqrt{n_j} + \beta_2 x_{2j}\sqrt{n_j} + u_j\sqrt{n_j}$$

This regression will reproduce the coefficients and covariance matrix produced by the aweighted regression. The mean squared errors (estimates of the variance of the residuals) will, however, be different. The transformed regression reports s_t^2, an estimate of $\mathrm{Var}(u_j\sqrt{n_j})$. The aweighted regression reports s_a^2, an estimate of $\mathrm{Var}(u_j\sqrt{n_j}\sqrt{N/\sum_k n_k})$, where N is the number of observations. Thus

$$s_a^2 = \frac{N}{\sum_k n_k} s_t^2 = \frac{s_t^2}{\overline{n}} \tag{1}$$

The logic for this adjustment is as follows: Consider the model

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + u$$

Assume that, were this model fit on individuals, $\mathrm{Var}(u) = \sigma_u^2$, a constant. Assume that individual data are not available; what is available are averages $(\overline{y}_j, \overline{x}_{1j}, \overline{x}_{2j})$ for $j = 1, \ldots, N$, and each average is calculated over n_j observations. Then it is still true that

$$\overline{y}_j = \beta_0 + \beta_1\overline{x}_{1j} + \beta_2\overline{x}_{2j} + \overline{u}_j$$

where $\overline{u}_j$ is the average of n_j mean 0, variance σ_u^2 deviates and has variance $\sigma_{\overline{u}}^2 = \sigma_u^2/n_j$. Thus multiplying through by $\sqrt{n_j}$ produces

$$\overline{y}_j\sqrt{n_j} = \beta_0\sqrt{n_j} + \beta_1\overline{x}_{1j}\sqrt{n_j} + \beta_2\overline{x}_{2j}\sqrt{n_j} + \overline{u}_j\sqrt{n_j}$$

and $\mathrm{Var}(\overline{u}_j\sqrt{n_j}) = \sigma_u^2$. The mean squared error, s_t^2, reported by fitting this transformed regression is an estimate of σ_u^2. The coefficients and covariance matrix could also be obtained by aweighted regress. The only difference would be in the reported mean squared error, which from (1) is $\sigma_u^2/\overline{n}$. On average, each observation in the data reflects the averages calculated over $\overline{n} = \sum_k n_k/N$ individuals, and thus this reported mean squared error is the average variance of an observation in the dataset. We can retrieve the estimate of σ_u^2 by multiplying the reported mean squared error by $\overline{n}$.

More generally, aweights are used to solve general heteroskedasticity problems. In these cases, we have the model

$$y_j = \beta_0 + \beta_1 x_{1j} + \beta_2 x_{2j} + u_j$$

and the variance of u_j is thought to be proportional to a_j. If the variance is proportional to a_j, it is also proportional to αa_j, where α is any positive constant. Not quite arbitrarily, but with no loss of generality, we could choose $\alpha = \sum_k (1/a_k)/N$, the average value of the inverse of a_j. We can then write $\mathrm{Var}(u_j) = k\alpha a_j \sigma^2$, where k is the constant of proportionality that is no longer a function of the scale of the weights.

Dividing this regression through by the $\sqrt{a_j}$,

$$y_j/\sqrt{a_j} = \beta_0/\sqrt{a_j} + \beta_1 x_{1j}/\sqrt{a_j} + \beta_2 x_{2j}/\sqrt{a_j} + u_j/\sqrt{a_j}$$

produces a model with $\mathrm{Var}(u_j/\sqrt{a_j}) = k\alpha\sigma^2$, which is the constant part of $\mathrm{Var}(u_j)$. This variance is a function of α, the average of the reciprocal weights; if the weights are scaled arbitrarily, then so is this variance.

We can also fit this model by typing

```
. regress y x1 x2 [aweight=1/a]
```

This input will produce the same estimates of the coefficients and covariance matrix; the reported mean squared error is, from (1), $\{N/\sum_k (1/a_k)\} k\alpha\sigma^2 = k\sigma^2$. This variance is independent of the scale of a_j.

❑

Instrumental variables and two-stage least-squares regression

An alternate syntax for `regress` can be used to produce instrumental-variables (two-stage least squares) estimates.

`regress` *depvar* [*varlist*$_1$ [`(`*varlist*$_2$`)`]] [*if*] [*in*] [*weight*] [`,` *regress_options*]

This syntax is used mainly by programmers developing estimators using the instrumental-variables estimates as intermediate results. `ivregress` is normally used to directly fit these models; see [R] **ivregress**.

With this syntax, `regress` fits a structural equation of *depvar* on *varlist*$_1$ using instrumental variables regression; `(`*varlist*$_2$`)` indicates the list of instrumental variables. With the exception of `vce(hc2)` and `vce(hc3)`, all standard `regress` options are allowed.

Saved results

`regress` saves the following in `e()`:

Scalars

`e(N)`	number of observations
`e(mss)`	model sum of squares
`e(df_m)`	model degrees of freedom
`e(rss)`	residual sum of squares
`e(df_r)`	residual degrees of freedom
`e(r2)`	R-squared
`e(r2_a)`	adjusted R-squared
`e(F)`	F statistic
`e(rmse)`	root mean squared error
`e(ll)`	log likelihood under additional assumption of i.i.d. normal errors
`e(ll_0)`	log likelihood, constant-only model
`e(N_clust)`	number of clusters
`e(rank)`	rank of `e(V)`

Macros

`e(cmd)`	`regress`
`e(cmdline)`	command as typed
`e(depvar)`	name of dependent variable
`e(model)`	`ols` or `iv`
`e(wtype)`	weight type
`e(wexp)`	weight expression
`e(title)`	title in estimation output when `vce()` is not `ols`
`e(clustvar)`	name of cluster variable
`e(vce)`	*vcetype* specified in `vce()`
`e(vcetype)`	title used to label Std. Err.
`e(properties)`	`b V`
`e(estat_cmd)`	program used to implement `estat`
`e(predict)`	program used to implement `predict`
`e(marginsok)`	predictions allowed by `margins`
`e(asbalanced)`	factor variables `fvset` as `asbalanced`
`e(asobserved)`	factor variables `fvset` as `asobserved`

Matrices

`e(b)`	coefficient vector
`e(V)`	variance–covariance matrix of the estimators
`e(V_modelbased)`	model-based variance

Functions

`e(sample)`	marks estimation sample

Methods and formulas

`regress` is implemented as an ado-file.

Methods and formulas are presented under the following headings:

Coefficient estimation and ANOVA table
A general notation for the robust variance calculation
Robust calculation for regress

Coefficient estimation and ANOVA table

Variables printed in lowercase and not boldfaced (for example, x) are scalars. Variables printed in lowercase and boldfaced (for example, $\mathbf{x}$) are column vectors. Variables printed in uppercase and boldfaced (for example, $\mathbf{X}$) are matrices.

Let $\mathbf{v}$ be a column vector of weights specified by the user. If no weights are specified, $\mathbf{v} = \mathbf{1}$. Let $\mathbf{w}$ be a column vector of normalized weights. If no weights are specified or if the user specified `fweights` or `iweights`, $\mathbf{w} = \mathbf{v}$. Otherwise, $\mathbf{w} = \{\mathbf{v}/(\mathbf{1}'\mathbf{v})\}(\mathbf{1}'\mathbf{1})$.

The *number of observations*, n, is defined as $\mathbf{1}'\mathbf{w}$. For `iweights`, this is truncated to an integer. The *sum of the weights* is $\mathbf{1}'\mathbf{v}$. Define $c = 1$ if there is a constant in the regression and zero otherwise. Define k as the number of right-hand-side variables (including the constant).

Let $\mathbf{X}$ denote the matrix of observations on the right-hand-side variables, $\mathbf{y}$ the vector of observations on the left-hand-side variable, and $\mathbf{Z}$ the matrix of observations on the instruments. If the user specifies no instruments, then $\mathbf{Z} = \mathbf{X}$. In the following formulas, if the user specifies weights, then $\mathbf{X}'\mathbf{X}$, $\mathbf{X}'\mathbf{y}$, $\mathbf{y}'\mathbf{y}$, $\mathbf{Z}'\mathbf{Z}$, $\mathbf{Z}'\mathbf{X}$, and $\mathbf{Z}'\mathbf{y}$ are replaced by $\mathbf{X}'\mathbf{D}\mathbf{X}$, $\mathbf{X}'\mathbf{D}\mathbf{y}$, $\mathbf{y}'\mathbf{D}\mathbf{y}$, $\mathbf{Z}'\mathbf{D}\mathbf{Z}$, $\mathbf{Z}'\mathbf{D}\mathbf{X}$, and $\mathbf{Z}'\mathbf{D}\mathbf{y}$, respectively, where $\mathbf{D}$ is a diagonal matrix whose diagonal elements are the elements of $\mathbf{w}$. We suppress the $\mathbf{D}$ below to simplify the notation.

If no instruments are specified, define $\mathbf{A}$ as $\mathbf{X}'\mathbf{X}$ and $\mathbf{a}$ as $\mathbf{X}'\mathbf{y}$. Otherwise, define $\mathbf{A}$ as $\mathbf{X}'\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}(\mathbf{X}'\mathbf{Z})'$ and $\mathbf{a}$ as $\mathbf{X}'\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'\mathbf{y}$.

The coefficient vector $\mathbf{b}$ is defined as $\mathbf{A}^{-1}\mathbf{a}$. Although not shown in the notation, unless `hascons` is specified, $\mathbf{A}$ and $\mathbf{a}$ are accumulated in deviation form and the constant is calculated separately. This comment applies to all statistics listed below.

The *total sum of squares*, TSS, equals $\mathbf{y}'\mathbf{y}$ if there is no intercept and $\mathbf{y}'\mathbf{y} - \{(\mathbf{1}'\mathbf{y})^2/n\}$ otherwise. The *degrees of freedom* is $n - c$.

The *error sum of squares*, ESS, is defined as $\mathbf{y}'\mathbf{y} - 2\mathbf{b}\mathbf{X}'\mathbf{y} + \mathbf{b}'\mathbf{X}'\mathbf{X}\mathbf{b}$ if there are instruments and as $\mathbf{y}'\mathbf{y} - \mathbf{b}'\mathbf{X}'\mathbf{y}$ otherwise. The *degrees of freedom* is $n - k$.

The *model sum of squares*, MSS, equals TSS − ESS. The *degrees of freedom* is $k - c$.

The *mean squared error*, s^2, is defined as ESS$/(n - k)$. The *root mean squared error* is s, its square root.

The F statistic with $k - c$ and $n - k$ degrees of freedom is defined as

$$F = \frac{\text{MSS}}{(k-c)s^2}$$

if no instruments are specified. If instruments are specified and $c = 1$, then F is defined as

$$F = \frac{(\mathbf{b}-\mathbf{c})'\mathbf{A}(\mathbf{b}-\mathbf{c})}{(k-1)s^2}$$

where $\mathbf{c}$ is a vector of $k-1$ zeros and kth element $\mathbf{1}'\mathbf{y}/n$. Otherwise, F is defined as *missing*. (Here you may use the `test` command to construct any F test that you wish.)

The *R-squared*, R^2, is defined as $R^2 = 1 - \text{ESS}/\text{TSS}$.

The *adjusted R-squared*, R_a^2, is $1 - (1 - R^2)(n - c)/(n - k)$.

If `vce(robust)` is not specified, the conventional estimate of variance is $s^2\mathbf{A}^{-1}$. The handling of `vce(robust)` is described below.

A general notation for the robust variance calculation

Put aside all context of linear regression and the notation that goes with it—we will return to it. First, we are going to establish a notation for describing robust variance calculations.

The calculation formula for the robust variance calculation is

$$\widehat{\mathcal{V}} = q_c \widehat{\mathbf{V}} \Big(\sum_{k=1}^{M} \mathbf{u}_k^{(G)\prime} \mathbf{u}_k^{(G)} \Big) \widehat{\mathbf{V}}$$

where

$$\mathbf{u}_k^{(G)} = \sum_{j \in G_k} w_j \mathbf{u}_j$$

$G_1, G_2, \ldots, G_M$ are the clusters specified by `vce(cluster` *clustvar*`)`, and w_j are the user-specified weights, normalized if `aweight`s or `pweight`s are specified and equal to 1 if no weights are specified.

For `fweight`s without clusters, the variance formula is

$$\widehat{\mathcal{V}} = q_c \widehat{\mathbf{V}} \Big(\sum_{j=1}^{N} w_j \mathbf{u}_j' \mathbf{u}_j \Big) \widehat{\mathbf{V}}$$

which is the same as expanding the dataset and making the calculation on the unweighted data.

If `vce(cluster` *clustvar*`)` is not specified, $M = N$, and each cluster contains 1 observation. The inputs into this calculation are

- $\widehat{\mathbf{V}}$, which is typically a conventionally calculated variance matrix;
- $\mathbf{u}_j$, $j = 1, \ldots, N$, a row vector of scores; and
- q_c, a constant finite-sample adjustment.

Thus we can now describe how estimators apply the robust calculation formula by defining $\widehat{\mathbf{V}}$, $\mathbf{u}_j$, and q_c.

Two definitions are popular enough for q_c to deserve a name. The regression-like formula for q_c (Fuller et al. 1986) is

$$q_c = \frac{N-1}{N-k} \frac{M}{M-1}$$

where M is the number of clusters and N is the number of observations. For weights, N refers to the sum of the weights if weights are frequency weights and the number of observations in the dataset (ignoring weights) in all other cases. Also note that, weighted or not, $M = N$ when `vce(cluster` *clustvar*`)` is not specified, and then $q_c = N/(N-k)$.

The asymptotic-like formula for q_c is

$$q_c = \frac{M}{M-1}$$

where $M = N$ if `vce(cluster` *clustvar*`)` is not specified.

See [U] **20.20 Obtaining robust variance estimates** and [P] **_robust** for a discussion of the robust variance estimator and a development of these formulas.

Robust calculation for regress

For `regress`, $\widehat{\mathbf{V}} = \mathbf{A}^{-1}$. The other terms are

No instruments, `vce(robust)`, but not `vce(hc2)` or `vce(hc3)`,

$$\mathbf{u}_j = (y_j - \mathbf{x}_j\mathbf{b})\mathbf{x}_j$$

and q_c is given by its regression-like definition.

No instruments, `vce(hc2)`,

$$\mathbf{u}_j = \frac{1}{\sqrt{1-h_{jj}}}(y_j - \mathbf{x}_j\mathbf{b})\mathbf{x}_j$$

where $q_c = 1$ and $h_{jj} = \mathbf{x}_j(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_j'$.

No instruments, `vce(hc3)`,

$$\mathbf{u}_j = \frac{1}{1-h_{jj}}(y_j - \mathbf{x}_j\mathbf{b})\mathbf{x}_j$$

where $q_c = 1$ and $h_{jj} = \mathbf{x}_j(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_j'$.

Instrumental variables,

$$\mathbf{u}_j = (y_j - \mathbf{x}_j\mathbf{b})\widehat{\mathbf{x}}_j$$

where q_c is given by its regression-like definition, and

$$\widehat{\mathbf{x}}_j' = \mathbf{P}\mathbf{z}_j'$$

where $\mathbf{P} = (\mathbf{X}'\mathbf{Z})(\mathbf{Z}'\mathbf{Z})^{-1}$.

Acknowledgments

The robust estimate of variance was first implemented in Stata by Mead Over, Center for Global Development; Dean Jolliffe, World Bank; and Andrew Foster, Department of Economics, Brown University (Over, Jolliffe, and Foster 1996).

The history of regression is long and complicated: the books by Stigler (1986) and Hald (1998) are devoted largely to the story. Legendre published first on least squares in 1805. Gauss published later in 1809, but he had the idea earlier. Gauss, and especially Laplace, tied least squares to a normal errors assumption. The idea of the normal distribution can itself be traced back to De Moivre in 1733. Laplace discussed a variety of other estimation methods and error assumptions over his long career, while linear models long predate either innovation. Most of this work was linked to problems in astronomy and geodesy.

A second wave of ideas started when Galton used graphical and descriptive methods on data bearing on heredity to develop what he called regression. His term reflects the common phenomenon that characteristics of offspring are positively correlated with those of parents but with regression slope such that offspring "regress toward the mean". Galton's work was rather intuitive: contributions from Pearson, Edgeworth, Yule, and others introduced more formal machinery, developed related ideas on correlation, and extended application into the biological and social sciences. So most of the elements of regression as we know it were in place by 1900.

Pierre-Simon Laplace (1749–1827) was born in Normandy and was early recognized as a remarkable mathematician. He weathered a changing political climate well enough to rise to Minister of the Interior under Napoleon in 1799 (although only for 6 weeks) and to be made a Marquis by Louis XVIII in 1817. He made many contributions to mathematics and physics, his two main interests being theoretical astronomy and probability theory (including statistics). Laplace transforms are named for him.

Adrien-Marie Legendre (1752–1833) was born in Paris (or possibly in Toulouse) and educated in mathematics and physics. He worked in number theory, geometry, differential equations, calculus, function theory, applied mathematics, and geodesy. The Legendre polynomials are named for him. His main contribution to statistics is as one of the discoverers of least squares. He died in poverty, having refused to bow to political pressures.

Johann Carl Friedrich Gauss (1777–1855) was born in Braunschweig (Brunswick), now in Germany. He studied there and at Göttingen. His doctoral dissertation at the University of Helmstedt was a discussion of the fundamental theorem of algebra. He made many fundamental contributions to geometry, number theory, algebra, real analysis, differential equations, numerical analysis, statistics, astronomy, optics, geodesy, mechanics, and magnetism. An outstanding genius, Gauss worked mostly in isolation in Göttingen.

Francis Galton (1822–1911) was born in Birmingham, England, into a well-to-do family with many connections: he and Charles Darwin were first cousins. After an unsuccessful foray into medicine, he became independently wealthy at the death of his father. Galton traveled widely in Europe, the Middle East, and Africa, and became celebrated as an explorer and geographer. His pioneering work on weather maps helped in the identification of anticyclones, which he named. From about 1865, most of his work was centered on quantitative problems in biology, anthropology, and psychology. In a sense, Galton (re)invented regression, and he certainly named it. Galton also promoted the normal distribution, correlation approaches, and the use of median and selected quantiles as descriptive statistics. He was knighted in 1909.

Title

regress postestimation — Postestimation tools for regress

Description

The following postestimation commands are of special interest after `regress`:

Command	Description
`dfbeta`	DFBETA influence statistics
`estat hettest`	tests for heteroskedasticity
`estat imtest`	information matrix test
`estat ovtest`	Ramsey regression specification-error test for omitted variables
`estat szroeter`	Szroeter's rank test for heteroskedasticity
`estat vif`	variance inflation factors for the independent variables
`acprplot`	augmented component-plus-residual plot
`avplot`	added-variable plot
`avplots`	all added-variables plots in one image
`cprplot`	component-plus-residual plot
`lvr2plot`	leverage-versus-squared-residual plot
`rvfplot`	residual-versus-fitted plot
`rvpplot`	residual-versus-predictor plot

These commands are not appropriate after the `svy` prefix.

For information about these commands, see below.

The following standard postestimation commands are also available:

Command	Description
`contrast`	contrasts and ANOVA-style joint tests of estimates
`estat`	AIC, BIC, VCE, and estimation sample summary
`estat (svy)`	postestimation statistics for survey data
`estimates`	cataloging estimation results
`hausman`	Hausman's specification test
`lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
`linktest`	link test for model specification
`lrtest`[1]	likelihood-ratio test
`margins`	marginal means, predictive margins, marginal effects, and average marginal effects
`marginsplot`	graph the results from margins (profile plots, interaction plots, etc.)
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions, residuals, influence statistics, and other diagnostic measures
`predictnl`	point estimates, standard errors, testing, and inference for generalized predictions
`pwcompare`	pairwise comparisons of estimates
`suest`	seemingly unrelated estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

[1] `lrtest` is not appropriate with `svy` estimation results.

See the corresponding entries in the *Base Reference Manual* for details, but see [SVY] **estat** for details about `estat` (svy).

For postestimation tests specific to time series, see [R] **regress postestimation time series**.

Special-interest postestimation commands

These commands provide tools for diagnosing sensitivity to individual observations, analyzing residuals, and assessing specification.

`dfbeta` will calculate one, more than one, or all the DFBETAs after `regress`. Although `predict` will also calculate DFBETAs, `predict` can do this for only one variable at a time. `dfbeta` is a convenience tool for those who want to calculate DFBETAs for multiple variables. The names for the new variables created are chosen automatically and begin with the letters `_dfbeta_`.

`estat hettest` performs three versions of the Breusch–Pagan (1979) and Cook–Weisberg (1983) test for heteroskedasticity. All three versions of this test present evidence against the null hypothesis that $\mathbf{t} = \mathbf{0}$ in $\mathrm{Var}(e) = \sigma^2\exp(\mathbf{zt})$. In the `normal` version, performed by default, the null hypothesis also includes the assumption that the regression disturbances are independent-normal draws with variance σ^2. The normality assumption is dropped from the null hypothesis in the `iid` and `fstat` versions, which respectively produce the score and F tests discussed in *Methods and formulas*. If *varlist* is not specified, the fitted values are used for $\mathbf{z}$. If *varlist* or the `rhs` option is specified, the variables specified are used for $\mathbf{z}$.

`estat imtest` performs an information matrix test for the regression model and an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis due to Cameron and Trivedi (1990);

White's test for homoskedasticity against unrestricted forms of heteroskedasticity (1980) is available as an option. White's test is usually similar to the first term of the Cameron–Trivedi decomposition.

`estat ovtest` performs two versions of the Ramsey (1969) regression specification-error test (RESET) for omitted variables. This test amounts to fitting $y = \mathbf{xb} + \mathbf{zt} + u$ and then testing $\mathbf{t} = \mathbf{0}$. If the `rhs` option is not specified, powers of the fitted values are used for $\mathbf{z}$. If `rhs` is specified, powers of the individual elements of $\mathbf{x}$ are used.

`estat szroeter` performs Szroeter's rank test for heteroskedasticity for each of the variables in *varlist* or for the explanatory variables of the regression if `rhs` is specified.

`estat vif` calculates the centered or uncentered variance inflation factors (VIFs) for the independent variables specified in a linear regression model.

`acprplot` graphs an augmented component-plus-residual plot (a.k.a. augmented partial residual plot) as described by Mallows (1986). This seems to work better than the component-plus-residual plot for identifying nonlinearities in the data.

`avplot` graphs an added-variable plot (a.k.a. partial-regression leverage plot, partial regression plot, or adjusted partial residual plot) after `regress`. *indepvar* may be an independent variable (a.k.a. predictor, carrier, or covariate) that is currently in the model or not.

`avplots` graphs all the added-variable plots in one image.

`cprplot` graphs a component-plus-residual plot (a.k.a. partial residual plot) after `regress`. *indepvar* must be an independent variable that is currently in the model.

`lvr2plot` graphs a leverage-versus-squared-residual plot (a.k.a. L-R plot).

`rvfplot` graphs a residual-versus-fitted plot, a graph of the residuals against the fitted values.

`rvpplot` graphs a residual-versus-predictor plot (a.k.a. independent variable plot or carrier plot), a graph of the residuals against the specified predictor.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

statistic	Description
Main	
`xb`	linear prediction; the default
`residuals`	residuals
`score`	score; equivalent to `residuals`
`rstandard`	standardized residuals
`rstudent`	Studentized (jackknifed) residuals
`cooksd`	Cook's distance
`leverage` | `hat`	leverage (diagonal elements of hat matrix)
`pr(`*a*`,`*b*`)`	$\Pr(y_j \mid a < y_j < b)$
`e(`*a*`,`*b*`)`	$E(y_j \mid a < y_j < b)$
`ystar(`*a*`,`*b*`)`	$E(y_j^*)$, $y_j^* = \max\{a, \min(y_j, b)\}$
* `dfbeta(`*varname*`)`	DFBETA for *varname*
`stdp`	standard error of the linear prediction
`stdf`	standard error of the forecast
`stdr`	standard error of the residual
* `covratio`	COVRATIO
* `dfits`	DFITS
* `welsch`	Welsch distance

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`rstandard`, `rstudent`, `cooksd`, `leverage`, `dfbeta()`, `stdf`, `stdr`, `covratio`, `dfits`, and `welsch` are not available if any `vce()` other than `vce(ols)` was specified with `regress`.

`xb`, `residuals`, `score`, and `stdp` are the only options allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing ($a \geq .$) means $-\infty$, and *b* missing ($b \geq .$) means $+\infty$; see [U] **12.2.1 Missing values**.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals.

`score` is equivalent to `residuals` in linear regression.

`rstandard` calculates the standardized residuals.

`rstudent` calculates the Studentized (jackknifed) residuals.

`cooksd` calculates the Cook's D influence statistic (Cook 1977).

`leverage` or `hat` calculates the diagonal elements of the projection hat matrix.

`pr(`*a*`,`*b*`)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b).

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;
`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,`*ub*`)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and
`pr(20,`*ub*`)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;
`pr(`*lb*`,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which $lb \geq .$
and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;
`pr(20,`*ub*`)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which $ub \geq .$
and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(`*a*`,`*b*`)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b), meaning that $y_j|\mathbf{x}_j$ is truncated.
a and *b* are specified as they are for `pr()`.

`ystar(`*a*`,`*b*`)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`dfbeta(`*varname*`)` calculates the DFBETA for *varname*, the difference between the regression coefficient when the jth observation is included and excluded, said difference being scaled by the estimated standard error of the coefficient. *varname* must have been included among the regressors in the previously fitted model. The calculation is automatically restricted to the estimation subsample.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas*.

`stdr` calculates the standard error of the residuals.

`covratio` calculates COVRATIO (Belsley, Kuh, and Welsch 1980), a measure of the influence of the jth observation based on considering the effect on the variance–covariance matrix of the estimates. The calculation is automatically restricted to the estimation subsample.

`dfits` calculates DFITS (Welsch and Kuh 1977) and attempts to summarize the information in the leverage versus residual-squared plot into one statistic. The calculation is automatically restricted to the estimation subsample.

`welsch` calculates Welsch distance (Welsch 1982) and is a variation on `dfits`. The calculation is automatically restricted to the estimation subsample.

Syntax for dfbeta

`dfbeta` [*indepvar* [*indepvar* [...]]] [`, stub(`*name*`)`]

Menu

Statistics > Linear models and related > Regression diagnostics > DFBETAs

Option for dfbeta

`stub(`*name*`)` specifies the leading characters `dfbeta` uses to name the new variables to be generated. The default is `stub(_dfbeta_)`.

Syntax for estat hettest

`estat hettest` [*varlist*] [`, rhs` [`normal` | `iid` | `fstat`] `mtest` [`(`*spec*`)`]]

Menu

Statistics > Postestimation > Reports and statistics

Options for estat hettest

`rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. The `rhs` option may be combined with a *varlist*.

`normal`, the default, causes `estat hettest` to compute the original Breusch–Pagan/Cook–Weisberg test, which assumes that the regression disturbances are normally distributed.

`iid` causes `estat hettest` to compute the $N * R^2$ version of the score test that drops the normality assumption.

`fstat` causes `estat hettest` to compute the F-statistic version that drops the normality assumption.

`mtest` [`(`*spec*`)`] specifies that multiple testing be performed. The argument specifies how p-values are adjusted. The following specifications, *spec*, are supported:

`bonferroni`	Bonferroni's multiple testing adjustment
`holm`	Holm's multiple testing adjustment
`sidak`	Šidák's multiple testing adjustment
`noadjust`	no adjustment is made for multiple testing

`mtest` may be specified without an argument. This is equivalent to specifying `mtest(noadjust)`; that is, tests for the individual variables should be performed with unadjusted p-values. By default, `estat hettest` does not perform multiple testing. `mtest` may not be specified with `iid` or `fstat`.

Syntax for estat imtest

`estat imtest` [`, preserve white`]

Menu

Statistics > Postestimation > Reports and statistics

Options for estat imtest

`preserve` specifies that the data in memory be preserved, all variables and cases that are not needed in the calculations be dropped, and at the conclusion the original data be restored. This option is costly for large datasets. However, because `estat imtest` has to perform an auxiliary regression on $k(k+1)/2$ temporary variables, where k is the number of regressors, it may not be able to perform the test otherwise.

`white` specifies that White's original heteroskedasticity test also be performed.

Syntax for estat ovtest

```
estat ovtest [ , rhs ]
```

Menu

Statistics > Postestimation > Reports and statistics

Option for estat ovtest

`rhs` specifies that powers of the right-hand-side (explanatory) variables be used in the test rather than powers of the fitted values.

Syntax for estat szroeter

```
estat szroeter [ varlist ] [ , rhs mtest(spec) ]
```

Either *varlist* or `rhs` must be specified.

Menu

Statistics > Postestimation > Reports and statistics

Options for estat szroeter

`rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. Option `rhs` may be combined with a *varlist*.

`mtest(`*spec*`)` specifies that multiple testing be performed. The argument specifies how p-values are adjusted. The following specifications, *spec*, are supported:

`bonferroni`	Bonferroni's multiple testing adjustment
`holm`	Holm's multiple testing adjustment
`sidak`	Šidák's multiple testing adjustment
`noadjust`	no adjustment is made for multiple testing

`estat szroeter` always performs multiple testing. By default, it does not adjust the p-values.

Syntax for estat vif

```
estat vif [, uncentered]
```

Menu

Statistics > Postestimation > Reports and statistics

Option for estat vif

`uncentered` requests that the computation of the uncentered variance inflation factors. This option is often used to detect the collinearity of the regressors with the constant. `estat vif, uncentered` may be used after regression models fit without the constant term.

Syntax for acprplot

```
acprplot indepvar [, acprplot_options]
```

acprplot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Options	
`lowess`	add a lowess smooth of the plotted points
`lsopts(`*lowess_options*`)`	affect rendition of the lowess smooth
`mspline`	add median spline of the plotted points
`msopts(`*mspline_options*`)`	affect rendition of the spline
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Linear models and related > Regression diagnostics > Augmented component-plus-residual plot

Options for acprplot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line. See [G-3] ***cline_options***.

Options

`lowess` adds a lowess smooth of the plotted points to assist in detecting nonlinearities.

`lsopts(`*lowess_options*`)` affects the rendition of the lowess smooth. For an explanation of these options, especially the `bwidth()` option, see [R] **lowess**. Specifying `lsopts()` implies the `lowess` option.

`mspline` adds a median spline of the plotted points to assist in detecting nonlinearities.

`msopts(`*mspline_options*`)` affects the rendition of the spline. For an explanation of these options, especially the `bands()` option, see [G-2] **graph twoway mspline**. Specifying `msopts()` implies the `mspline` option.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for avplot

`avplot` *indepvar* [`,` *avplot_options*]

avplot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

Options for avplot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line. See [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for avplots

`avplots` [`,` *avplots_options*]

avplots_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
combine_options	any of the options documented in [G-2] **graph combine**
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

Options for avplots

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

combine_options are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line. See [G-3] ***cline_options***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for cprplot

`cprplot` *indepvar* [`,` *cprplot_options*]

cprplot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Options	
`lowess`	add a lowess smooth of the plotted points
`lsopts(`*lowess_options*`)`	affect rendition of the lowess smooth
`mspline`	add median spline of the plotted points
`msopts(`*mspline_options*`)`	affect rendition of the spline
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Linear models and related > Regression diagnostics > Component-plus-residual plot

Options for cprplot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line. See [G-3] ***cline_options***.

Options

`lowess` adds a lowess smooth of the plotted points to assist in detecting nonlinearities.

`lsopts(`*lowess_options*`)` affects the rendition of the lowess smooth. For an explanation of these options, especially the `bwidth()` option, see [R] **lowess**. Specifying `lsopts()` implies the `lowess` option.

`mspline` adds a median spline of the plotted points to assist in detecting nonlinearities.

`msopts(`*mspline_options*`)` affects the rendition of the spline. For an explanation of these options, especially the `bands()` option, see [G-2] **graph twoway mspline**. Specifying `msopts()` implies the `mspline` option.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for lvr2plot

`lvr2plot` [`,` *lvr2plot_options*]

lvr2plot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Add plots	
`addplot(`*plot*`)`	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

Menu

Statistics > Linear models and related > Regression diagnostics > Leverage-versus-squared-residual plot

Options for lvr2plot

Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] ***marker_options***.

marker_label_options specify if and how the markers are to be labeled; see [G-3] ***marker_label_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Syntax for rvfplot

`rvfplot` [`,` *rvfplot_options*]

rvfplot_options	Description
Plot	
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
Add plots

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Remarks are presented under the following headings:

Fitted values and residuals
Prediction standard errors
Prediction with weighted data
Residual-versus-fitted plots
Added-variable plots
Component-plus-residual plots
Residual-versus-predictor plots
Leverage statistics
L-R plots
Standardized and Studentized residuals
DFITS, Cook's Distance, and Welsch Distance
COVRATIO
DFBETAs
Formal tests for violations of assumptions
Variance inflation factors

Many of these commands concern identifying influential data in linear regression. This is, unfortunately, a field that is dominated by jargon, codified and partially begun by Belsley, Kuh, and Welsch (1980). In the words of Chatterjee and Hadi (1986, 416), "Belsley, Kuh, and Welsch's book, *Regression Diagnostics*, was a very valuable contribution to the statistical literature, but it unleashed on an unsuspecting statistical community a computer speak (à la Orwell), the likes of which we have never seen." Things have only gotten worse since then. Chatterjee and Hadi's (1986, 1988) own attempts to clean up the jargon did not improve matters (see Hoaglin and Kempthorne [1986], Velleman [1986], and Welsch [1986]). We apologize for the jargon, and for our contribution to the jargon in the form of inelegant command names, we apologize most of all.

Model *sensitivity* refers to how estimates are affected by subsets of our data. Imagine data on y and x, and assume that the data are to be fit by the regression $y_i = \alpha + \beta x_i + \epsilon_i$. The regression estimates of α and β are a and b, respectively. Now imagine that the estimated a and b would be different if a small portion of the dataset, perhaps even one observation, were deleted. As a data analyst, you would like to think that you are summarizing tendencies that apply to all the data, but you have just been told that the model you fit is unduly influenced by one point or just a few points and that, as a matter of fact, there is another model that applies to the rest of the data—a model that you have ignored. The search for subsets of the data that, if deleted, would change the results markedly is a predominant theme of this entry.

There are three key issues in identifying model sensitivity to individual observations, which go by the names *residuals*, *leverage*, and *influence*. In our $y_i = a + bx_i + e_i$ regression, the residuals are, of course, e_i—they reveal how much our fitted value $\widehat{y}_i = a + bx_i$ differs from the observed y_i. A point (x_i, y_i) with a corresponding large residual is called an outlier. Say that you are interested in outliers because you somehow think that such points will exert undue influence on your estimates. Your feelings are generally right, but there are exceptions. A point might have a huge residual and yet not affect the estimated b at all. Nevertheless, studying observations with large residuals almost always pays off.

(x_i, y_i) can be an outlier in another way—just as y_i can be far from $\widehat{y}_i$, x_i can be far from the center of mass of the other x's. Such an "outlier" should interest you just as much as the more traditional outliers. Picture a scatterplot of y against x with thousands of points in some sort of mass at the lower left of the graph and one point at the upper right of the graph. Now run a regression line through the points—the regression line will come close to the point at the upper right of the graph and may in fact, go through it. That is, this isolated point will not appear as an outlier as measured by residuals because its residual will be small. Yet this point might have a dramatic effect on our resulting estimates in the sense that, were you to delete the point, the estimates would change

markedly. Such a point is said to have high leverage. Just as with traditional outliers, a high leverage point does not necessarily have an undue effect on regression estimates, but if it does not, it is more the exception than the rule.

Now all this is a most unsatisfactory state of affairs. Points with large residuals may, but need not, have a large effect on our results, and points with small residuals may still have a large effect. Points with high leverage may, but need not, have a large effect on our results, and points with low leverage may still have a large effect. Can you not identify the influential points and simply have the computer list them for you? You can, but you will have to define what you mean by "influential".

"Influential" is defined with respect to some statistic. For instance, you might ask which points in your data have a large effect on your estimated a, which points have a large effect on your estimated b, which points have a large effect on your estimated standard error of b, and so on, but do not be surprised when the answers to these questions are different. In any case, obtaining such measures is not difficult—all you have to do is fit the regression excluding each observation one at a time and record the statistic of interest which, in the day of the modern computer, is not too onerous. Moreover, you can save considerable computer time by doing algebra ahead of time and working out formulas that will calculate the same answers as if you ran each of the regressions. (Ignore the question of pairs of observations that, together, exert undue influence, and triples, and so on, which remains largely unsolved and for which the brute force fit-every-possible-regression procedure is not a viable alternative.)

Fitted values and residuals

Typing `predict` *newvar* with no options creates *newvar* containing the fitted values. Typing `predict` *newvar*`, resid` creates *newvar* containing the residuals.

▷ Example 1

Continuing with example 1 from [R] **regress**, we wish to fit the following model:

$$\texttt{mpg} = \beta_0 + \beta_1\texttt{weight} + \beta_2\texttt{weight}^2 + \beta_3\texttt{foreign} + \epsilon$$

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight c.weight#c.weight foreign
```

Source	SS	df	MS		
Model	1689.15372	3	563.05124	Number of obs	= 74
Residual	754.30574	70	10.7757963	F(3, 70)	= 52.25
				Prob > F	= 0.0000
				R-squared	= 0.6913
				Adj R-squared	= 0.6781
Total	2443.45946	73	33.4720474	Root MSE	= 3.2827

mpg	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	-.0165729	.0039692	-4.18	0.000	-.0244892	-.0086567
c.weight# c.weight	1.59e-06	6.25e-07	2.55	0.013	3.45e-07	2.84e-06
foreign	-2.2035	1.059246	-2.08	0.041	-4.3161	-.0909002
_cons	56.53884	6.197383	9.12	0.000	44.17855	68.89913

That done, we can now obtain the predicted values from the regression. We will store them in a new variable called pmpg by typing predict pmpg. Because predict produces no output, we will follow that by summarizing our predicted and observed values.

```
. predict pmpg
(option xb assumed; fitted values)
. summarize pmpg mpg
    Variable |        Obs        Mean    Std. Dev.       Min        Max
-------------+---------------------------------------------------------
        pmpg |         74     21.2973    4.810311   13.59953   31.86288
         mpg |         74     21.2973    5.785503         12         41
```

◁

▷ Example 2: Out-of-sample predictions

We can just as easily obtain predicted values from the model by using a wholly different dataset from the one on which the model was fit. The only requirement is that the data have the necessary variables, which here are weight and foreign.

Using the data on two new cars (the Pontiac Sunbird and the Volvo 260) from the newautos.dta dataset, we can obtain out-of-sample predictions (or forecasts) by typing

```
. use http://www.stata-press.com/data/r12/newautos, clear
(New Automobile Models)
. predict pmpg
(option xb assumed; fitted values)
. list, divider
```

	make	weight	foreign	pmpg
1.	Pont. Sunbird	2690	Domestic	23.47137
2.	Volvo 260	3170	Foreign	17.78846

The Pontiac Sunbird has a predicted mileage rating of 23.5 mpg, whereas the Volvo 260 has a predicted rating of 17.8 mpg. In comparison, the actual mileage ratings are 24 for the Pontiac and 17 for the Volvo.

◁

Prediction standard errors

predict can calculate the standard error of the forecast (stdf option), the standard error of the prediction (stdp option), and the standard error of the residual (stdr option). It is easy to confuse stdf and stdp because both are often called the prediction error. Consider the prediction $\widehat{y}_j = \mathbf{x}_j\mathbf{b}$, where $\mathbf{b}$ is the estimated coefficient (column) vector and $\mathbf{x}_j$ is a (row) vector of independent variables for which you want the prediction. First, $\widehat{y}_j$ has a variance due to the variance of the estimated coefficient vector $\mathbf{b}$,

$$\mathrm{Var}(\widehat{y}_j) = \mathrm{Var}(\mathbf{x}_j\mathbf{b}) = s^2 h_j$$

where $h_j = \mathbf{x}_j(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_j'$ and s^2 is the mean squared error of the regression. Do not panic over the algebra—just remember that $\mathrm{Var}(\widehat{y}_j) = s^2 h_j$, whatever s^2 and h_j are. stdp calculates this quantity. This is the error in the prediction due to the uncertainty about $\mathbf{b}$.

If you are about to hand this number out as your forecast, however, there is another error. According to your model, the true value of y_j is given by

$$y_j = \mathbf{x}_j\mathbf{b} + \epsilon_j = \widehat{y}_j + \epsilon_j$$

and thus the $\mathrm{Var}(y_j) = \mathrm{Var}(\widehat{y}_j) + \mathrm{Var}(\epsilon_j) = s^2h_j + s^2$, which is the square of `stdf`. `stdf`, then, is the sum of the error in the prediction plus the residual error.

`stdr` has to do with an analysis-of-variance decomposition of s^2, the estimated variance of y. The standard error of the prediction is s^2h_j, and therefore $s^2h_j + s^2(1 - h_j) = s^2$ decomposes s^2 into the prediction and residual variances.

▷ Example 3: standard error of the forecast

Returning to our model of `mpg` on `weight`, `weight`^{2}, and `foreign`, we previously predicted the mileage rating for the Pontiac Sunbird and Volvo 260 as 23.5 and 17.8 mpg, respectively. We now want to put a standard error around our forecast. Remember, the data for these two cars were in `newautos.dta`:

```
. use http://www.stata-press.com/data/r12/newautos, clear
(New Automobile Models)
. predict pmpg
(option xb assumed; fitted values)
. predict se_pmpg, stdf
. list, divider
```

	make	weight	foreign	pmpg	se_pmpg
1.	Pont. Sunbird	2690	Domestic	23.47137	3.341823
2.	Volvo 260	3170	Foreign	17.78846	3.438714

Thus an approximate 95% confidence interval for the mileage rating of the Volvo 260 is $17.8 \pm 2 \cdot 3.44 = [\,10.92, 24.68\,]$.

◁

Prediction with weighted data

`predict` can be used after frequency-weighted (`fweight`) estimation, just as it is used after unweighted estimation. The technical note below concerns the use of `predict` after analytically weighted (`aweight`) estimation.

❑ Technical note

After analytically weighted estimation, `predict` is willing to calculate only the prediction (no options), residual (`residual` option), standard error of the prediction (`stdp` option), and diagonal elements of the projection matrix (`hat` option). Moreover, the results produced by `hat` need to be adjusted, as will be described. For analytically weighted estimation, the standard error of the forecast and residuals, the standardized and Studentized residuals, and Cook's D are not statistically well-defined concepts.

To obtain the correct values of the diagonal elements of the hat matrix, you can use `predict` with the `hat` option to make a first, partially adjusted calculation, and then follow that by completing the adjustment. Assume that you are fitting a linear regression model weighting the data with the variable `w` (`[aweight=w]`). Begin by creating a new variable, `w0`:

```
. predict resid if e(sample), resid
. summarize w if resid < . & e(sample)
. gen w0=w/r(mean)
```

Some caution is necessary at this step—the `summarize w` must be performed on the same sample that was used to fit the model, which means that you must include `if e(sample)` to restrict the prediction to the estimation sample. You created the residual and then included the modifier '`if resid < .`' so that if the dependent variable or any of the independent variables is missing, the corresponding observations will be excluded from the calculation of the average value of the original weight.

To correct `predict`'s `hat` calculation, multiply the result by `w0`:

```
. predict myhat, hat
. replace myhat = w0 * myhat
```

❑

Residual-versus-fitted plots

▷ Example 4: rvfplot

Using the automobile dataset described in [U] **1.2.2 Example datasets**, we will use `regress` to fit a model of `price` on `weight`, `mpg`, `foreign`, and the interaction of `foreign` with `mpg`. We specify `foreign##c.mpg` to obtain the interaction of `foreign` with `mpg`; see [U] **11.4.3 Factor variables**.

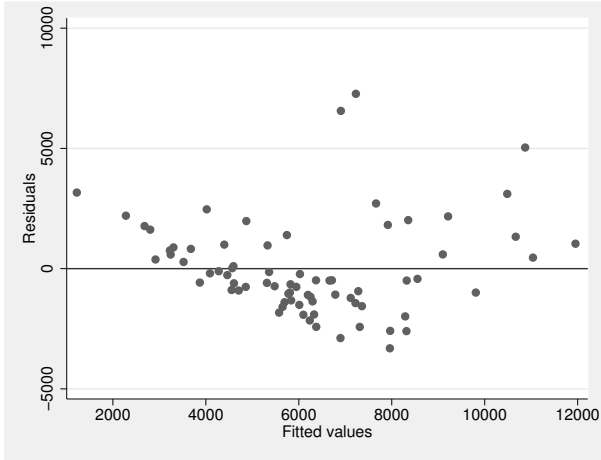
```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. regress price weight foreign##c.mpg
```

Source	SS	df	MS	Number of obs =	74
				F(4, 69) =	21.22
Model	350319665	4	87579916.3	Prob > F =	0.0000
Residual	284745731	69	4126749.72	R-squared =	0.5516
				Adj R-squared =	0.5256
Total	635065396	73	8699525.97	Root MSE =	2031.4

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
weight	4.613589	.7254961	6.36	0.000	3.166263	6.060914
1.foreign	11240.33	2751.681	4.08	0.000	5750.878	16729.78
mpg	263.1875	110.7961	2.38	0.020	42.15527	484.2197
foreign# c.mpg 1	-307.2166	108.5307	-2.83	0.006	-523.7294	-90.70368
_cons	-14449.58	4425.72	-3.26	0.002	-23278.65	-5620.51

Once we have fit a model, we may use any of the regression diagnostics commands. `rvfplot` (read residual-versus-fitted plot) graphs the residuals against the fitted values:

```
. rvfplot, yline(0)
```



All the diagnostic plot commands allow the `graph twoway` and `graph twoway scatter` options; we specified a `yline(0)` to draw a line across the graph at $y = 0$; see [G-2] **graph twoway scatter**.

In a well-fitted model, there should be no pattern to the residuals plotted against the fitted values—something not true of our model. Ignoring the two outliers at the top center of the graph, we see curvature in the pattern of the residuals, suggesting a violation of the assumption that `price` is linear in our independent variables. We might also have seen increasing or decreasing variation in the residuals—heteroskedasticity. Any pattern whatsoever indicates a violation of the least-squares assumptions.

◁

Added-variable plots

▷ Example 5: avplot

We continue with our price model, and another diagnostic graph is provided by `avplot` (read added-variable plot, also known as the partial-regression leverage plot).

One of the wonderful features of one-regressor regressions (regressions of y on one x) is that we can graph the data and the regression line. There is no easier way to understand the regression than to examine such a graph. Unfortunately, we cannot do this when we have more than one regressor. With two regressors, it is still theoretically possible—the graph must be drawn in three dimensions, but with three or more regressors no graph is possible.

The added-variable plot is an attempt to project multidimensional data back to the two-dimensional world for each of the original regressors. This is, of course, impossible without making some concessions. Call the coordinates on an added-variable plot y and x. The added-variable plot has the following properties:

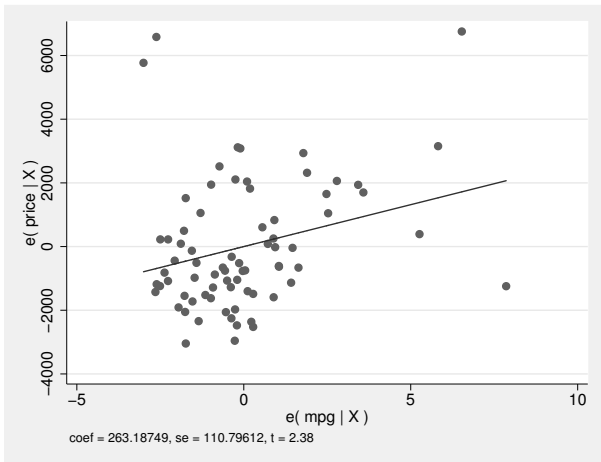
- There is a one-to-one correspondence between (x_i, y_i) and the ith observation used in the original regression.
- A regression of y on x has the same coefficient and standard error (up to a degree-of-freedom adjustment) as the estimated coefficient and standard error for the regressor in the original regression.

- The "outlierness" of each observation in determining the slope is in some sense preserved.

It is equally important to note the properties that are not listed. The y and x coordinates of the added-variable plot cannot be used to identify functional form, or, at least, not well (see Mallows [1986]). In the construction of the added-variable plot, the relationship between y and x is forced to be linear.

Let's examine the added-variable plot for `mpg` in our regression of `price` on `weight` and `foreign##c.mpg`:

```
. avplot mpg
```



This graph suggests a problem in determining the coefficient on `mpg`. Were this a one-regressor regression, the two points at the top-left corner and the one at the top right would cause us concern, and so it does in our more complicated multiple-regressor case. To identify the problem points, we retyped our command, modifying it to read `avplot mpg, mlabel(make)`, and discovered that the two cars at the top left are the Cadillac Eldorado and the Lincoln Versailles; the point at the top right is the Cadillac Seville. These three cars account for 100% of the luxury cars in our data, suggesting that our model is misspecified. By the way, the point at the lower right of the graph, also cause for concern, is the Plymouth Arrow, our data-entry error.

◁

❑ Technical note

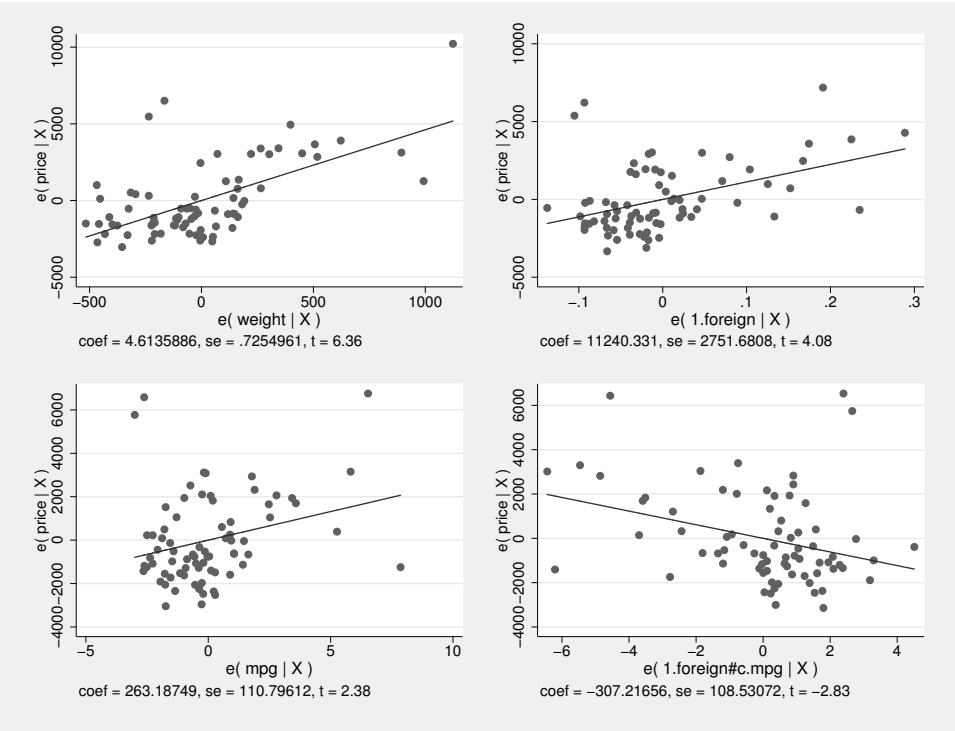
Stata's `avplot` command can be used with regressors already in the model, as we just did, or with potential regressors not yet in the model. In either case, `avplot` will produce the correct graph. The name "added-variable plot" is unfortunate in the case when the variable is already among the list of regressors but is, we think, still preferable to the name "partial-regression leverage plot" assigned by Belsley, Kuh, and Welsch (1980, 30) and more in the spirit of the original use of such plots by Mosteller and Tukey (1977, 271–279). Welsch (1986, 403), however, disagrees: "I am sorry to see that Chatterjee and Hadi [1986] endorse the term 'added-variable plot' when X_j is part of the original model" and goes on to suggest the name "adjusted partial residual plot".

❑

▷ Example 6: avplots

Added-variable plots are so useful that we should look at them for every regressor in the data. `avplots` makes this easy:

```
. avplots
```



◁

Component-plus-residual plots

Added-variable plots are successful at identifying outliers, but they cannot be used to identify functional form. The component-plus-residual plot (Ezekiel 1924; Larsen and McCleary 1972) is another attempt at projecting multidimensional data into a two-dimensional form, but with different properties. Although the added-variable plot can identify outliers, the component-plus-residual plot cannot. It can, however, be used to examine the functional-form assumptions of the model. Both plots have the property that a regression line through the coordinates has a slope equal to the estimated coefficient in the regression model.

▷ Example 7: cprplot and acprplot

To illustrate these plots, we begin with a different model:

```
. use http://www.stata-press.com/data/r12/auto1, clear
(Automobile Models)

. regress price mpg weight
```

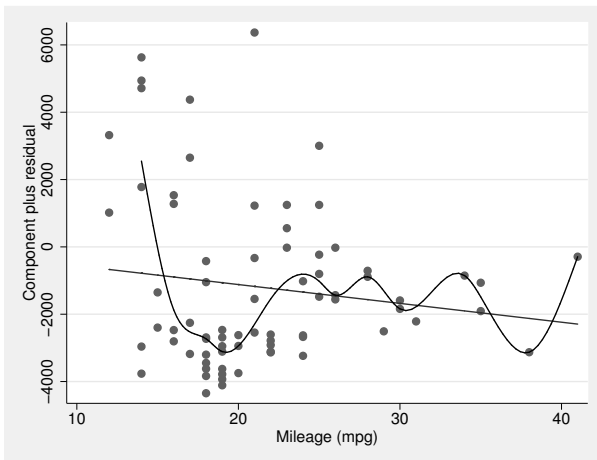
Source	SS	df	MS	Number of obs =	74
				F(2, 71) =	14.90
Model	187716578	2	93858289	Prob > F =	0.0000
Residual	447348818	71	6300687.58	R-squared =	0.2956
				Adj R-squared =	0.2757
Total	635065396	73	8699525.97	Root MSE =	2510.1

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
mpg	-55.9393	75.24136	-0.74	0.460	-205.9663	94.08771
weight	1.710992	.5861682	2.92	0.005	.5422063	2.879779
_cons	2197.9	3190.768	0.69	0.493	-4164.311	8560.11

In fact, we know that the effects of `mpg` in this model are nonlinear—if we added `mpg` squared to the model, its coefficient would have a t statistic of 2.38, the t statistic on `mpg` would become -2.48, and `weight`'s effect would become about one-third of its current value and become statistically insignificant. Pretend that we do not know this.

The component-plus-residual plot for `mpg` is

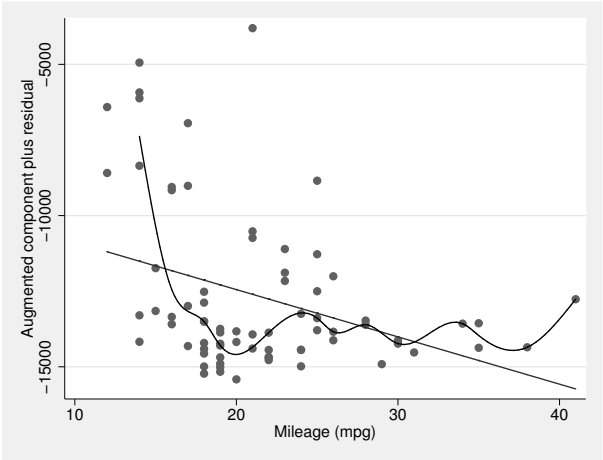
```
. cprplot mpg, mspline msopts(bands(13))
```



We are supposed to examine the above graph for nonlinearities or, equivalently, ask if the regression line, which has slope equal to the estimated effect of `mpg` in the original model, fits the data adequately. To assist our eyes, we added a median spline. Perhaps some people may detect nonlinearity from this graph, but we assert that if we had not previously revealed the nonlinearity of `mpg` and if we had not added the median spline, the graph would not overly bother us.

Mallows (1986) proposed an augmented component-plus-residual plot that is often more sensitive to detecting nonlinearity:

```
. acprplot mpg, mspline msopts(bands(13))
```



It does do somewhat better.

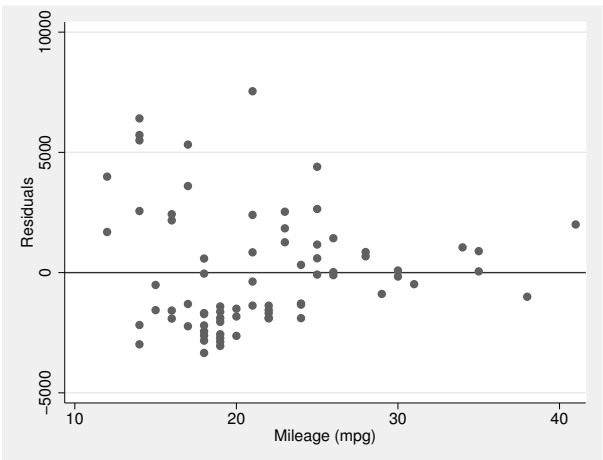
◁

Residual-versus-predictor plots

▷ Example 8: rvpplot

The residual-versus-predictor plot is a simple way to look for violations of the regression assumptions. If the assumptions are correct, there should be no pattern in the graph. Using our `price` on `mpg` and `weight` model, we type

```
. rvpplot mpg, yline(0)
```



Remember, any pattern counts as a problem, and in this graph, we see that the variation in the residuals decreases as `mpg` increases.

◁

Leverage statistics

In addition to providing fitted values and the associated standard errors, the `predict` command can also be used to generate various statistics used to detect the influence of individual observations. This section provides a brief introduction to leverage (hat) statistics, and some of the following subsections discuss other influence statistics produced by `predict`.

▷ Example 9: diagonal elements of projection matrix

The diagonal elements of the projection matrix, obtained by the `hat` option, are a measure of distance in explanatory variable space. `leverage` is a synonym for `hat`.

```
. use http://www.stata-press.com/data/r12/auto
(1978 Automobile Data)
. regress mpg weight c.weight#c.weight foreign
  (output omitted)
. predict xdist, hat
. summarize xdist, detail
                        Leverage
-------------------------------------------------------------
      Percentiles      Smallest
 1%     .0251334       .0251334
 5%     .0255623       .0251334
10%     .0259213       .0253883       Obs                  74
25%     .0278442       .0255623       Sum of Wgt.          74
50%       .04103                      Mean           .0540541
                       Largest        Std. Dev.      .0459218
75%     .0631279       .1593606
90%     .0854584       .1593606       Variance       .0021088
95%     .1593606       .2326124       Skewness       3.440809
99%     .3075759       .3075759       Kurtosis       16.95135
```

Some 5% of our sample has an `xdist` measure in excess of 0.15. Let's force them to reveal their identities:

```
. list foreign make mpg if xdist>.15, divider
```

	foreign	make	mpg
24.	Domestic	Ford Fiesta	28
26.	Domestic	Linc. Continental	12
27.	Domestic	Linc. Mark V	12
43.	Domestic	Plym. Champ	34

To understand why these cars are on this list, we must remember that the explanatory variables in our model are `weight` and `foreign` and that `xdist` measures distance in this metric. The Ford Fiesta and the Plymouth Champ are the two lightest domestic cars in our data. The Lincolns are the two heaviest domestic cars.

◁

L-R plots

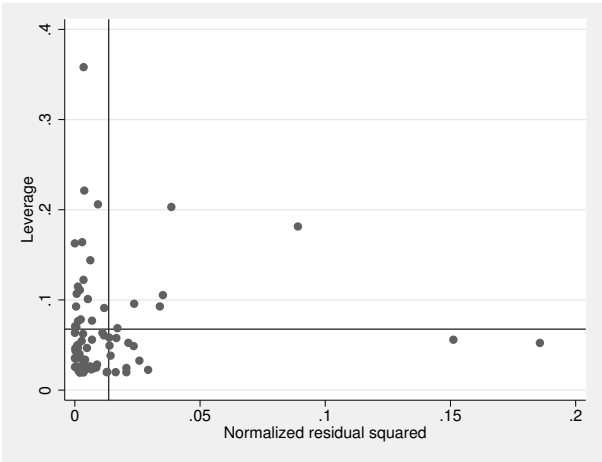
▷ Example 10: lvr2plot

One of the most useful diagnostic graphs is provided by `lvr2plot` (leverage-versus-residual-squared plot), a graph of leverage against the (normalized) residuals squared.

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. regress price weight foreign##c.mpg
```

(*output omitted*)

```
. lvr2plot
```

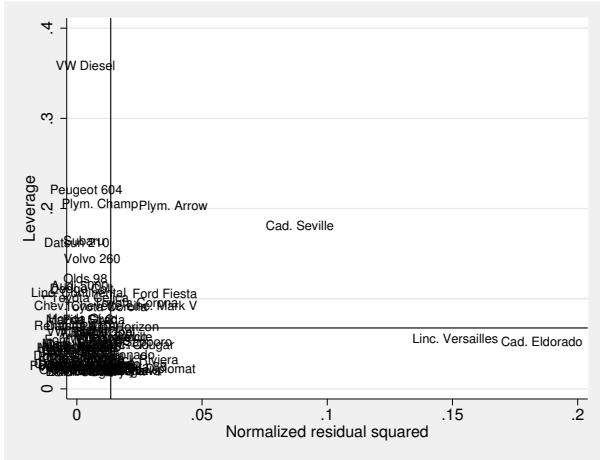


The lines on the chart show the average values of leverage and the (normalized) residuals squared. Points above the horizontal line have higher-than-average leverage; points to the right of the vertical line have larger-than-average residuals.

One point immediately catches our eye, and four more make us pause. The point at the top of the graph has high leverage and a smaller-than-average residual. The other points that bother us all have higher-than-average leverage, two with smaller-than-average residuals and two with larger-than-average residuals.

A less pretty but more useful version of the above graph specifies that `make` be used as the symbol (see [G-3] ***marker_label_options***):

```
. lvr2plot, mlabel(make) mlabp(0) m(none) mlabsize(small)
```



The VW Diesel, Plymouth Champ, Plymouth Arrow, and Peugeot 604 are the points that cause us the most concern. When we further examine our data, we discover that the VW Diesel is the only diesel in our data and that the data for the Plymouth Arrow were entered incorrectly into the computer. No such simple explanations were found for the Plymouth Champ and Peugeot 604.

◁

Standardized and Studentized residuals

The terms standardized and Studentized residuals have meant different things to different authors. In Stata, `predict` defines the standardized residual as $\widehat{e}_i = e_i/(s\sqrt{1-h_i})$ and the Studentized residual as $r_i = e_i/(s_{(i)}\sqrt{1-h_i})$, where $s_{(i)}$ is the root mean squared error of a regression with the ith observation removed. Stata's definition of the Studentized residual is the same as the one given in Bollen and Jackman (1990, 264) and is what Chatterjee and Hadi (1988, 74) call the "externally Studentized" residual. Stata's "standardized" residual is the same as what Chatterjee and Hadi (1988, 74) call the "internally Studentized" residual.

Standardized and Studentized residuals are attempts to adjust residuals for their standard errors. Although the ϵ_i theoretical residuals are homoskedastic by assumption (that is, they all have the same variance), the calculated e_i are not. In fact,

$$\mathrm{Var}(e_i) = \sigma^2(1-h_i)$$

where h_i are the leverage measures obtained from the diagonal elements of hat matrix. Thus observations with the greatest leverage have corresponding residuals with the smallest variance.

Standardized residuals use the root mean squared error of the regression for σ. Studentized residuals use the root mean squared error of a regression omitting the observation in question for σ. In general, Studentized residuals are preferable to standardized residuals for purposes of outlier identification. Studentized residuals can be interpreted as the t statistic for testing the significance of a dummy variable equal to 1 in the observation in question and 0 elsewhere (Belsley, Kuh, and Welsch 1980). Such a dummy variable would effectively absorb the observation and so remove its influence in determining the other coefficients in the model. Caution must be exercised here, however, because of the simultaneous testing problem. You cannot simply list the residuals that would be individually significant at the 5% level—their joint significance would be far less (their joint significance *level* would be far greater).

▷ Example 11: standardized and Studentized residuals

In the opening remarks for this entry, we distinguished residuals from leverage and speculated on the impact of an observation with a small residual but large leverage. If we had adjusted the residuals for their standard errors, however, the adjusted residual would have been (relatively) larger and perhaps large enough so that we could simply examine the adjusted residuals. Taking our `price` on `weight` and `foreign##c.mpg` model, we can obtain the in-sample standardized and Studentized residuals by typing

```
. predict esta if e(sample), rstandard
. predict estu if e(sample), rstudent
```

In *L-R plots*, we discovered that the VW Diesel has the highest leverage in our data, but a corresponding small residual. The standardized and Studentized residuals for the VW Diesel are

```
. list make price esta estu if make=="VW Diesel"
```

	make	price	esta	estu
74.	VW Diesel	5,397	.6142691	.6114758

The Studentized residual of 0.611 can be interpreted as the t statistic for including a dummy variable for VW Diesel in our regression. Such a variable would not be significant.

◁

DFITS, Cook's Distance, and Welsch Distance

DFITS (Welsch and Kuh 1977), Cook's Distance (Cook 1977), and Welsch Distance (Welsch 1982) are three attempts to summarize the information in the leverage versus residual-squared plot into one statistic. That is, the goal is to create an index that is affected by the size of the residuals—outliers—and the size of h_i—leverage. Viewed mechanically, one way to write DFITS (Bollen and Jackman 1990, 265) is

$$\text{DFITS}_i = r_i\sqrt{\frac{h_i}{1-h_i}}$$

where r_i are the Studentized residuals. Thus large residuals increase the value of DFITS, as do large values of h_i. Viewed more traditionally, DFITS is a scaled difference between predicted values for the ith case when the regression is fit with and without the ith observation, hence the name.

The mechanical relationship between DFITS and Cook's Distance, D_i (Bollen and Jackman 1990, 266), is

$$D_i = \frac{1}{k}\frac{s^2_{(i)}}{s^2}\text{DFITS}_i^2$$

where k is the number of variables (including the constant) in the regression, s is the root mean squared error of the regression, and $s_{(i)}$ is the root mean squared error when the ith observation is omitted. Viewed more traditionally, D_i is a scaled measure of the distance between the coefficient vectors when the ith observation is omitted.

The mechanical relationship between DFITS and Welsch's Distance, W_i (Chatterjee and Hadi 1988, 123), is

$$W_i = \text{DFITS}_i\sqrt{\frac{n-1}{1-h_i}}$$

The interpretation of W_i is more difficult, as it is based on the empirical influence curve. Although DFITS and Cook's distance are similar, the Welsch distance measure includes another normalization by leverage.

Belsley, Kuh, and Welsch (1980, 28) suggest that DFITS values greater than $2\sqrt{k/n}$ deserve more investigation, and so values of Cook's distance greater than $4/n$ should also be examined (Bollen and Jackman 1990, 265–266). Through similar logic, the cutoff for Welsch distance is approximately $3\sqrt{k}$ (Chatterjee and Hadi 1988, 124).

▷ Example 12: DFITS influence measure

Using our model of `price` on `weight` and `foreign##c.mpg`, we can obtain the DFITS influence measure:

```
. use http://www.stata-press.com/data/r12/auto, clear
(1978 Automobile Data)
. regress price weight foreign##c.mpg
  (output omitted)
. predict e if e(sample), resid
. predict dfits, dfits
```

We did not specify `if e(sample)` in computing the DFITS statistic. DFITS is available only over the estimation sample, so specifying `if e(sample)` would have been redundant. It would have done no harm, but it would not have changed the results.

Our model has $k = 5$ independent variables (k includes the constant) and $n = 74$ observations; following the $2\sqrt{k/n}$ cutoff advice, we type

```
. list make price e dfits if abs(dfits) > 2*sqrt(5/74), divider
```

	make	price	e	dfits
12.	Cad. Eldorado	14,500	7271.96	.9564455
13.	Cad. Seville	15,906	5036.348	1.356619
24.	Ford Fiesta	4,389	3164.872	.5724172
27.	Linc. Mark V	13,594	3109.193	.5200413
28.	Linc. Versailles	13,466	6560.912	.8760136
42.	Plym. Arrow	4,647	-3312.968	-.9384231

We calculate Cook's distance and list the observations greater than the suggested $4/n$ cutoff:

```
. predict cooksd if e(sample), cooksd
. list make price e cooksd if cooksd > 4/74, divider
```

	make	price	e	cooksd
12.	Cad. Eldorado	14,500	7271.96	.1492676
13.	Cad. Seville	15,906	5036.348	.3328515
24.	Ford Fiesta	4,389	3164.872	.0638815
28.	Linc. Versailles	13,466	6560.912	.1308004
42.	Plym. Arrow	4,647	-3312.968	.1700736

Here we used `if e(sample)` because Cook's distance is not restricted to the estimation sample by default. It is worth comparing this list with the preceding one.

Finally, we use Welsch distance and the suggested $3\sqrt{k}$ cutoff:

```
. predict wd, welsch
. list make price e wd if abs(wd) > 3*sqrt(5), divider
```

	make	price	e	wd
12.	Cad. Eldorado	14,500	7271.96	8.394372
13.	Cad. Seville	15,906	5036.348	12.81125
28.	Linc. Versailles	13,466	6560.912	7.703005
42.	Plym. Arrow	4,647	-3312.968	-8.981481

Here we did not need to specify `if e(sample)` because `welsch` automatically restricts the prediction to the estimation sample.

◁

COVRATIO

COVRATIO (Belsley, Kuh, and Welsch 1980) measures the influence of the ith observation by considering the effect on the variance–covariance matrix of the estimates. The measure is the ratio of the determinants of the covariances matrix, with and without the ith observation. The resulting formula is

$$\text{COVRATIO}_i = \frac{1}{1-h_i}\left(\frac{n-k-\widehat{e}_i^2}{n-k-1}\right)^k$$

where $\widehat{e}_i$ is the standardized residual.

For noninfluential observations, the value of COVRATIO is approximately 1. Large values of the residuals or large values of leverage will cause deviations from 1, although if both are large, COVRATIO may tend back toward 1 and therefore not identify such observations (Chatterjee and Hadi 1988, 139).

Belsley, Kuh, and Welsch (1980) suggest that observations for which

$$|\text{COVRATIO}_i - 1| \geq \frac{3k}{n}$$

are worthy of further examination.

▷ Example 13: COVRATIO influence measure

Using our model of `price` on `weight` and `foreign##c.mpg`, we can obtain the COVRATIO measure and list the observations outside the suggested cutoff by typing

```
. predict covr, covratio
. list make price e covr if abs(covr-1) >= 3*5/74, divider
```

	make	price	e	covr
12.	Cad. Eldorado	14,500	7271.96	.3814242
13.	Cad. Seville	15,906	5036.348	.7386969
28.	Linc. Versailles	13,466	6560.912	.4761695
43.	Plym. Champ	4,425	1621.747	1.27782
53.	Audi 5000	9,690	591.2883	1.206842
57.	Datsun 210	4,589	19.81829	1.284801
64.	Peugeot 604	12,990	1037.184	1.348219
66.	Subaru	3,798	-909.5894	1.264677
71.	VW Diesel	5,397	999.7209	1.630653
74.	Volvo 260	11,995	1327.668	1.211888

The `covratio` option automatically restricts the prediction to the estimation sample.

◁

DFBETAs

DFBETAs are perhaps the most direct influence measure of interest to model builders. DFBETAs focus on one coefficient and measure the difference between the regression coefficient when the ith observation is included and excluded, the difference being scaled by the estimated standard error of the coefficient. Belsley, Kuh, and Welsch (1980, 28) suggest observations with $|\text{DFBETA}_i| > 2/\sqrt{n}$ as deserving special attention, but it is also common practice to use 1 (Bollen and Jackman 1990, 267), meaning that the observation shifted the estimate at least one standard error.

▷ Example 14: DFBETAs influence measure; the dfbeta() option

Using our model of `price` on `weight` and `foreign##c.mpg`, let's first ask which observations have the greatest impact on the determination of the coefficient on `1.foreign`. We will use the suggested $2/\sqrt{n}$ cutoff:

```
. sort foreign make
. predict dfor, dfbeta(1.foreign)
. list make price foreign dfor if abs(dfor) > 2/sqrt(74), divider
```

	make	price	foreign	dfor
12.	Cad. Eldorado	14,500	Domestic	-.5290519
13.	Cad. Seville	15,906	Domestic	.8243419
28.	Linc. Versailles	13,466	Domestic	-.5283729
42.	Plym. Arrow	4,647	Domestic	-.6622424
43.	Plym. Champ	4,425	Domestic	.2371104
64.	Peugeot 604	12,990	Foreign	.2552032
69.	Toyota Corona	5,719	Foreign	-.256431

The Cadillac Seville shifted the coefficient on `1.foreign` 0.82 standard deviations!

Now let us ask which observations have the greatest effect on the mpg coefficient:

```
. predict dmpg, dfbeta(mpg)
. list make price mpg dmpg if abs(dmpg) > 2/sqrt(74), divider
```

	make	price	mpg	dmpg
12.	Cad. Eldorado	14,500	14	-.5970351
13.	Cad. Seville	15,906	21	1.134269
28.	Linc. Versailles	13,466	14	-.6069287
42.	Plym. Arrow	4,647	28	-.8925859
43.	Plym. Champ	4,425	34	.3186909

Once again we see the Cadillac Seville heading the list, indicating that our regression results may be dominated by this one car.

◁

▷ Example 15: DFBETAs influence measure; the dfbeta command

We can use `predict, dfbeta()` or the `dfbeta` command to generate the DFBETAs. `dfbeta` makes up names for the new variables automatically and, without arguments, generates the DFBETAs for all the variables in the regression:

```
. dfbeta
                        _dfbeta_1: dfbeta(weight)
                        _dfbeta_2: dfbeta(1.foreign)
                        _dfbeta_3: dfbeta(mpg)
                        _dfbeta_4: dfbeta(1.foreign#c.mpg)
```

`dfbeta` created four new variables in our dataset: `_dfbeta_1`, containing the DFBETAs for `weight`; `_dfbeta_2`, containing the DFBETAs for `mpg`; and so on. Had we wanted only the DFBETAs for `mpg` and `weight`, we might have typed

```
. dfbeta mpg weight
                        _dfbeta_5: dfbeta(weight)
                        _dfbeta_6: dfbeta(mpg)
```

In the example above, we typed `dfbeta mpg weight` instead of `dfbeta`; if we had typed `dfbeta` followed by `dfbeta mpg weight`, here is what would have happened:

```
. dfbeta
                        _dfbeta_7: dfbeta(weight)
                        _dfbeta_8: dfbeta(1.foreign)
                        _dfbeta_9: dfbeta(mpg)
                       _dfbeta_10: dfbeta(1.foreign#c.mpg)
. dfbeta mpg weight
                       _dfbeta_11: dfbeta(weight)
                       _dfbeta_12: dfbeta(mpg)
```

`dfbeta` would have made up different names for the new variables. `dfbeta` never replaces existing variables—it instead makes up a different name, so we need to pay attention to `dfbeta`'s output.

◁

Formal tests for violations of assumptions

This section introduces some regression diagnostic commands that are designed to test for certain violations that `rvfplot` less formally attempts to detect. `estat ovtest` provides Ramsey's test for omitted variables—a pattern in the residuals. `estat hettest` provides a test for heteroskedasticity—the increasing or decreasing variation in the residuals with fitted values, with respect to the explanatory variables, or with respect to yet other variables. The score test implemented in `estat hettest` (Breusch and Pagan 1979; Cook and Weisberg 1983) performs a score test of the null hypothesis that $b = 0$ against the alternative hypothesis of multiplicative heteroskedasticity. `estat szroeter` provides a rank test for heteroskedasticity, which is an alternative to the score test computed by `estat hettest`. Finally, `estat imtest` computes an information matrix test, including an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis (Cameron and Trivedi 1990). The heteroskedasticity test computed by `estat imtest` is similar to the general test for heteroskedasticity that was proposed by White (1980). Cameron and Trivedi (2010, chap. 3) discuss most of these tests and provides more examples.

▷ Example 16: estat ovtest, estat hettest, estat szroeter, and estat imtest

We run these commands just mentioned on our model:

```
. estat ovtest
Ramsey RESET test using powers of the fitted values of price
       Ho:  model has no omitted variables
                  F(3, 66) =      7.77
                  Prob > F =      0.0002
. estat hettest
Breusch-Pagan / Cook-Weisberg tests for heteroskedasticity
         Ho: Constant variance
         variables: fitted values of price
         chi2(1)      =     6.50
         Prob > chi2  =   0.0108
```

Testing for heteroskedasticity in the right-hand-side variables is requested by specifying the `rhs` option. By specifying the `mtest(bonferroni)` option, we request that tests be conducted for each of the variables, with a Bonferroni adjustment for the p-values to accommodate our testing multiple hypotheses.

```
. estat hettest, rhs mtest(bonf)
Breusch-Pagan / Cook-Weisberg test for heteroskedasticity
         Ho: Constant variance
```

Variable	chi2	df	p	
weight	15.24	1	0.0004	#
1.foreign	6.15	1	0.0525	#
mpg	9.04	1	0.0106	#
foreign# c.mpg				
1	6.02	1	0.0566	#
simultaneous	15.60	4	0.0036	

 # Bonferroni-adjusted p-values

```
. estat szroeter, rhs mtest(holm)
Szroeter's test for homoskedasticity
    Ho: variance constant
    Ha: variance monotonic in variable
```

Variable	chi2	df	p	
weight	17.07	1	0.0001	#
1.foreign	6.15	1	0.0131	#
mpg	11.45	1	0.0021	#
foreign# c.mpg				
1	6.17	1	0.0260	#

 # Holm adjusted p-values

Finally, we request the information matrix test, which is a conditional moments test with second-, third-, and fourth-order moment conditions.

```
. estat imtest
Cameron & Trivedi's decomposition of IM-test
```

Source	chi2	df	p
Heteroskedasticity	18.86	10	0.0420
Skewness	11.69	4	0.0198
Kurtosis	2.33	1	0.1273
Total	32.87	15	0.0049

We find evidence for omitted variables, heteroskedasticity, and nonnormal skewness.

So, why bother with the various graphical commands when the tests seem so much easier to interpret? In part, it is a matter of taste: both are designed to uncover the same problem, and both are, in fact, going about it in similar ways. One is based on a formal calculation, whereas the other is based on personal judgment in evaluating a graph. On the other hand, the tests are seeking evidence of specific problems, whereas judgment is more general. The careful analyst will use both.

We performed the omitted-variable test first. Omitted variables are a more serious problem than heteroskedasticity or the violations of higher moment conditions tested by `estat imtest`. If this were not a manual, having found evidence of omitted variables, we would never have run the `estat hettest`, `estat szroeter`, and `estat imtest` commands, at least not until we solved the omitted-variable problem.

◁

❑ Technical note

`estat ovtest` and `estat hettest` both perform two flavors of their respective tests. By default, `estat ovtest` looks for evidence of omitted variables by fitting the original model augmented by $\widehat{y}^2$, $\widehat{y}^3$, and $\widehat{y}^4$, which are the fitted values from the original model. Under the assumption of no misspecification, the coefficients on the powers of the fitted values will be zero. With the `rhs` option, `estat ovtest` instead augments the original model with powers (second through fourth) of the explanatory variables (except for dummy variables).

`estat hettest`, by default, looks for heteroskedasticity by modeling the variance as a function of the fitted values. If, however, we specify a variable or variables, the variance will be modeled as a function of the specified variables. In our example, if we had, a priori, some reason to suspect heteroskedasticity and that the heteroskedasticity is a function of a car's weight, then using a test that focuses on weight would be more powerful than the more general tests such as White's test or the first term in the Cameron–Trivedi decomposition test.

`estat hettest`, by default, computes the original Breusch–Pagan/Cook–Weisberg test, which includes the assumption of normally distributed errors. Koenker (1981) derived an $N * R^2$ version of this test that drops the normality assumption. Wooldridge (2009) gives an F-statistic version that does not require the normality assumption.

❑

Variance inflation factors

Problems arise in regression when the predictors are highly correlated. In this situation, there may be a significant change in the regression coefficients if you add or delete an independent variable. The estimated standard errors of the fitted coefficients are inflated, or the estimated coefficients may not be statistically significant even though a statistical relation exists between the dependent and independent variables.

Data analysts rely on these facts to check informally for the presence of multicollinearity. `estat vif`, another command for use after `regress`, calculates the variance inflation factors and tolerances for each of the independent variables.

The output shows the variance inflation factors together with their reciprocals. Some analysts compare the reciprocals with a predetermined tolerance. In the comparison, if the reciprocal of the VIF is smaller than the tolerance, the associated predictor variable is removed from the regression model. However, most analysts rely on informal rules of thumb applied to the VIF; see Chatterjee and Hadi (2006). According to these rules, there is evidence of multicollinearity if

1. The largest VIF is greater than 10 (some choose a more conservative threshold value of 30).
2. The mean of all the VIFs is considerably larger than 1.

▷ Example 17: estat vif

We examine a regression model fit using the ubiquitous automobile dataset:

```
. regress price mpg rep78 trunk headroom length turn displ gear_ratio
```

Source	SS	df	MS	Number of obs =	69
				F(8, 60) =	6.33
Model	264102049	8	33012756.2	Prob > F =	0.0000
Residual	312694909	60	5211581.82	R-squared =	0.4579
				Adj R-squared =	0.3856
Total	576796959	68	8482308.22	Root MSE =	2282.9

price	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
mpg	-144.84	82.12751	-1.76	0.083	-309.1195	19.43948
rep78	727.5783	337.6107	2.16	0.035	52.25638	1402.9
trunk	44.02061	108.141	0.41	0.685	-172.2935	260.3347
headroom	-807.0996	435.5802	-1.85	0.069	-1678.39	64.19061
length	-8.688914	34.89848	-0.25	0.804	-78.49626	61.11843
turn	-177.9064	137.3455	-1.30	0.200	-452.6383	96.82551
displacement	30.73146	7.576952	4.06	0.000	15.5753	45.88762
gear_ratio	1500.119	1110.959	1.35	0.182	-722.1303	3722.368
_cons	6691.976	7457.906	0.90	0.373	-8226.057	21610.01

```
. estat vif
    Variable |       VIF       1/VIF
-------------+----------------------
      length |      8.22    0.121614
displacement |      6.50    0.153860
        turn |      4.85    0.205997
  gear_ratio |      3.45    0.290068
         mpg |      3.03    0.330171
       trunk |      2.88    0.347444
    headroom |      1.80    0.554917
      rep78 |      1.46    0.686147
-------------+----------------------
    Mean VIF |      4.02
```

The results are mixed. Although we have no VIFs greater than 10, the mean VIF is greater than 1, though not considerably so. We could continue the investigation of collinearity, but given that other authors advise that collinearity is a problem only when VIFs exist that are greater than 30 (contradicting our rule above), we will not do so here.

◁

▷ Example 18: estat vif, with strong evidence of multicollinearity

This example comes from a dataset described in Kutner, Nachtsheim, and Neter (2004, 257) that examines body fat as modeled by caliper measurements on the triceps, midarm, and thigh.

```
. use http://www.stata-press.com/data/r12/bodyfat, clear
(Body Fat)
. regress bodyfat tricep thigh midarm
      Source |       SS       df       MS              Number of obs =      20
-------------+------------------------------           F(  3,    16) =   21.52
       Model |  396.984607     3  132.328202            Prob > F      =  0.0000
    Residual |  98.4049068    16  6.15030667            R-squared     =  0.8014
-------------+------------------------------           Adj R-squared =  0.7641
       Total |  495.389513    19  26.0731323            Root MSE      =    2.48

------------------------------------------------------------------------------
     bodyfat |      Coef.   Std. Err.      t    P>|t|     [95% Conf. Interval]
-------------+----------------------------------------------------------------
     triceps |   4.334085   3.015511     1.44   0.170    -2.058512    10.72668
       thigh |  -2.856842   2.582015    -1.11   0.285    -8.330468    2.616785
     midarm |  -2.186056   1.595499    -1.37   0.190    -5.568362     1.19625
       _cons |   117.0844   99.78238     1.17   0.258    -94.44474    328.6136
------------------------------------------------------------------------------
. estat vif
    Variable |       VIF       1/VIF
-------------+----------------------
     triceps |    708.84    0.001411
       thigh |    564.34    0.001772
     midarm |    104.61    0.009560
-------------+----------------------
    Mean VIF |    459.26
```

Here we see strong evidence of multicollinearity in our model. More investigation reveals that the measurements on the thigh and the triceps are highly correlated:

```
. corr triceps thigh midarm
(obs=20)
```

	triceps	thigh	midarm
triceps	1.0000		
thigh	0.9238	1.0000	
midarm	0.4578	0.0847	1.0000

If we remove the predictor `tricep` from the model (because it had the highest VIF), we get

```
. regress bodyfat thigh midarm
```

Source	SS	df	MS		
Model	384.279748	2	192.139874	Number of obs	= 20
Residual	111.109765	17	6.53586854	F(2, 17)	= 29.40
				Prob > F	= 0.0000
Total	495.389513	19	26.0731323	R-squared	= 0.7757
				Adj R-squared	= 0.7493
				Root MSE	= 2.5565

bodyfat	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
thigh	.8508818	.1124482	7.57	0.000	.6136367	1.088127
midarm	.0960295	.1613927	0.60	0.560	-.2444792	.4365383
_cons	-25.99696	6.99732	-3.72	0.002	-40.76001	-11.2339

```
. estat vif
```

Variable	VIF	1/VIF
midarm	1.01	0.992831
thigh	1.01	0.992831
Mean VIF	1.01	

Note how the coefficients change and how the estimated standard errors for each of the regression coefficients become much smaller. The calculated value of R^2 for the overall regression for the subset model does not appreciably decline when we remove the correlated predictor. Removing an independent variable from the model is one way to deal with multicollinearity. Other methods include ridge regression, weighted least squares, and restricting the use of the fitted model to data that follow the same pattern of multicollinearity. In economic studies, it is sometimes possible to estimate the regression coefficients from different subsets of the data by using cross-section and time series.

◁

All examples above demonstrated the use of centered VIFs. As pointed out by Belsley (1991), the centered VIFs may fail to discover collinearity involving the constant term. One solution is to use the uncentered VIFs instead. According to the definition of the uncentered VIFs, the constant is viewed as a legitimate explanatory variable in a regression model, which allows one to obtain the VIF value for the constant term.

▷ Example 19: estat vif, with strong evidence of collinearity with the constant term

Consider the extreme example in which one of the regressors is highly correlated with the constant. We simulate the data and examine both centered and uncentered VIF diagnostics after fitted regression model as follows.

```
. use http://www.stata-press.com/data/r12/extreme_collin
. summarize
  (output omitted)
. regress y one x z
```

Source	SS	df	MS	Number of obs = 100
Model	223801.985	3	74600.6617	F(3, 96) = 2710.27
Residual	2642.42124	96	27.5252213	Prob > F = 0.0000
				R-squared = 0.9883
Total	226444.406	99	2287.31723	Adj R-squared = 0.9880
				Root MSE = 5.2464

y	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
one	-3.278582	10.5621	-0.31	0.757	-24.24419	17.68702
x	2.038696	.0242673	84.01	0.000	1.990526	2.086866
z	4.863137	.2681036	18.14	0.000	4.330956	5.395319
_cons	9.760075	10.50935	0.93	0.355	-11.10082	30.62097

```
. estat vif
```

Variable	VIF	1/VIF
z	1.03	0.968488
x	1.03	0.971307
one	1.00	0.995425
Mean VIF	1.02	

```
. estat vif, uncentered
```

Variable	VIF	1/VIF
one	402.94	0.002482
intercept	401.26	0.002492
z	2.93	0.341609
x	1.13	0.888705
Mean VIF	202.06	

According to the values of the centered VIFs (1.03, 1.03, 1.00), no harmful collinearity is detected in the model. However, by the construction of these simulated data, we know that `one` is highly collinear with the constant term. As such, the large values of uncentered VIFs for `one` (402.94) and `intercept` (401.26) reveal high collinearity of the variable `one` with the constant term.

◁

Saved results

`estat hettest` saves the following results for the (multivariate) score test in `r()`:

Scalars

`r(chi2)`	χ^2 test statistic
`r(df)`	#df for the asymptotic χ^2 distribution under H_0
`r(p)`	p-value

`estat hettest, fstat` saves results for the (multivariate) score test in `r()`:

Scalars

`r(F)`	test statistic
`r(df_m)`	#df of the test for the F distribution under H_0
`r(df_r)`	#df of the residuals for the F distribution under H_0
`r(p)`	p-value

`estat hettest` (if `mtest` is specified) and `estat szroeter` save the following in `r()`:

Matrices

`r(mtest)`	a matrix of test results, with rows corresponding to the univariate tests
	`mtest[.,1]` χ^2 test statistic
	`mtest[.,2]` #df
	`mtest[.,3]` unadjusted p-value
	`mtest[.,4]` adjusted p-value (if an `mtest()` adjustment method is specified)

Macros

`r(mtmethod)`	adjustment method for p-values

`estat imtest` saves the following in `r()`:

Scalars

`r(chi2_t)`	IM-test statistic $\big(=$ `r(chi2_h)` $+$ `r(chi2_s)` $+$ `r(chi2_k)`$\big)$
`r(df_t)`	df for limiting χ^2 distribution under H_0 $\big(=$ `r(df_h)` $+$ `r(df_s)` $+$ `r(df_k)`$\big)$
`r(chi2_h)`	heteroskedasticity test statistic
`r(df_h)`	df for limiting χ^2 distribution under H_0
`r(chi2_s)`	skewness test statistic
`r(df_s)`	df for limiting χ^2 distribution under H_0
`r(chi2_k)`	kurtosis test statistic
`r(df_k)`	df for limiting χ^2 distribution under H_0
`r(chi2_w)`	White's heteroskedasticity test (if `white` specified)
`r(df_w)`	df for limiting χ^2 distribution under H_0

`estat ovtest` saves the following in `r()`:

Scalars

`r(p)`	two-sided p-value
`r(F)`	F statistic
`r(df)`	degrees of freedom
`r(df_r)`	residual degrees of freedom

Methods and formulas

All regression fit and diagnostic commands are implemented as ado-files.

See Hamilton (2009, chap. 7), Kohler and Kreuter (2009, sec. 8.3), or Baum (2006, chap. 5) for an overview of using Stata to perform regression diagnostics. See Peracchi (2001, chap. 8) for a mathematically rigorous discussion of diagnostics.

Methods and formulas are presented under the following headings:

predict
Special-interest postestimation commands

predict

Assume that you have already fit the regression model

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where $\mathbf{X}$ is $n \times k$.

Denote the previously estimated coefficient vector by $\mathbf{b}$ and its estimated variance matrix by $\mathbf{V}$. `predict` works by recalling various aspects of the model, such as $\mathbf{b}$, and combining that information with the data currently in memory. Let $\mathbf{x}_j$ be the jth observation currently in memory, and let s^2 be the mean squared error of the regression.

Let $\mathbf{V} = s^2(\mathbf{X}'\mathbf{X})^{-1}$. Let k be the number of independent variables including the intercept, if any, and let y_j be the observed value of the dependent variable.

The *predicted value* (`xb` option) is defined as $\widehat{y}_j = \mathbf{x}_j\mathbf{b}$.

Let ℓ_j represent a lower bound for an observation j and u_j represent an upper bound. The probability that $y_j|\mathbf{x}_j$ would be observed in the interval (ℓ_j, u_j)—the `pr(`ℓ`, `u`)` option—is

$$P(\ell_j, u_j) = \Pr(\ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j) = \Phi\left(\frac{u_j - \widehat{y}_j}{s}\right) - \Phi\left(\frac{\ell_j - \widehat{y}_j}{s}\right)$$

where for the `pr(`ℓ`, `u`)`, `e(`ℓ`, `u`)`, and `ystar(`ℓ`, `u`)` options, ℓ_j and u_j can be anywhere in the range $(-\infty, +\infty)$.

The option `e(`ℓ`, `u`)` computes the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (ℓ_j, u_j), that is, when $y_j|\mathbf{x}_j$ is truncated. It can be expressed as

$$E(\ell_j, u_j) = E(\mathbf{x}_j\mathbf{b} + e_j \mid \ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j) = \widehat{y}_j - s\frac{\phi\left(\frac{u_j - \widehat{y}_j}{s}\right) - \phi\left(\frac{\ell_j - \widehat{y}_j}{s}\right)}{\Phi\left(\frac{u_j - \widehat{y}_j}{s}\right) - \Phi\left(\frac{\ell_j - \widehat{y}_j}{s}\right)}$$

where ϕ is the normal density and Φ is the cumulative normal.

You can also compute `ystar(`ℓ, u`)`—the expected value of $y_j|\mathbf{x}_j$, where y_j is assumed censored at ℓ_j and u_j:

$$y_j^* = \begin{cases} \ell_j & \text{if } \mathbf{x}_j\mathbf{b} + e_j \le \ell_j \\ \mathbf{x}_j\mathbf{b} + u & \text{if } \ell_j < \mathbf{x}_j\mathbf{b} + e_j < u_j \\ u_j & \text{if } \mathbf{x}_j\mathbf{b} + e_j \ge u_j \end{cases}$$

This computation can be expressed in several ways, but the most intuitive formulation involves a combination of the two statistics just defined:

$$y_j^* = P(-\infty, \ell_j)\ell_j + P(\ell_j, u_j)E(\ell_j, u_j) + P(u_j, +\infty)u_j$$

A diagonal element of the projection matrix (`hat`) or (`leverage`) is given by

$$h_j = \mathbf{x}_j(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_j'$$

The *standard error of the prediction* (the `stdp` option) is defined as $s_{p_j} = \sqrt{\mathbf{x}_j\mathbf{V}\mathbf{x}_j'}$

and can also be written as $s_{p_j} = s\sqrt{h_j}$.

The *standard error of the forecast* (`stdf`) is defined as $s_{f_j} = s\sqrt{1 + h_j}$.

The *standard error of the residual* (`stdr`) is defined as $s_{r_j} = s\sqrt{1 - h_j}$.

The *residuals* (`residuals`) are defined as $\widehat{e}_j = y_j - \widehat{y}_j$.

The *standardized residuals* (`rstandard`) are defined as $\widehat{e}_{s_j} = \widehat{e}_j / s_{r_j}$.

The *Studentized residuals* (`rstudent`) are defined as

$$r_j = \frac{\widehat{e}_j}{s_{(j)}\sqrt{1 - h_j}}$$

where $s_{(j)}$ represents the root mean squared error with the jth observation removed, which is given by

$$s^2_{(j)} = \frac{s^2(T - k)}{T - k - 1} - \frac{\widehat{e}_j^2}{(T - k - 1)(1 - h_j)}$$

Cook's D (`cooksd`) is given by

$$D_j = \frac{\widehat{e}_{s_j}^2 (s_{p_j}/s_{r_j})^2}{k} = \frac{h_j \widehat{e}_j^2}{k s^2 (1 - h_j)^2}$$

DFITS (`dfits`) is given by

$$\text{DFITS}_j = r_j \sqrt{\frac{h_j}{1 - h_j}}$$

Welsch distance (`welsch`) is given by

$$W_j = \frac{r_j \sqrt{h_j (n - 1)}}{1 - h_j}$$

COVRATIO (`covratio`) is given by

$$\text{COVRATIO}_j = \frac{1}{1 - h_j} \left(\frac{n - k - \widehat{e}_j^2}{n - k - 1} \right)^k$$

The DFBETAs (`dfbeta`) for a particular regressor x_i are given by

$$\text{DFBETA}_j = \frac{r_j u_j}{\sqrt{U^2 (1 - h_j)}}$$

where u_j are the residuals obtained from a regression of x_i on the remaining x's and $U^2 = \sum_j u_j^2$.

Special-interest postestimation commands

The `lvr2plot` command plots leverage against the squares of the normalized residuals. The normalized residuals are defined as $\widehat{e}_{n_j} = \widehat{e}_j/(\sum_i \widehat{e}_i^2)^{1/2}$.

The omitted-variable test (Ramsey 1969) reported by `estat ovtest` fits the regression $y_i = \mathbf{x}_i\mathbf{b} + \mathbf{z}_i\mathbf{t} + u_i$ and then performs a standard F test of $\mathbf{t} = \mathbf{0}$. The default test uses $\mathbf{z}_i = (\widehat{y}_i^2, \widehat{y}_i^3, \widehat{y}_i^4)$. If `rhs` is specified, $\mathbf{z}_i = (x_{1i}^2, x_{1i}^3, x_{1i}^4, x_{2i}^2, \ldots, x_{mi}^4)$. In either case, the variables are normalized to have minimum 0 and maximum 1 before powers are calculated.

The test for heteroskedasticity (Breusch and Pagan 1979; Cook and Weisberg 1983) models $\mathrm{Var}(e_i) = \sigma^2 \exp(\mathbf{zt})$, where $\mathbf{z}$ is a variable list specified by the user, the list of right-hand-side variables, or the fitted values $\mathbf{x}\widehat{\beta}$. The test is of $\mathbf{t} = \mathbf{0}$. Mechanically, `estat hettest` fits the augmented regression $\widehat{e}_i^2/\widehat{\sigma}^2 = a + \mathbf{z}_i\mathbf{t} + v_i$.

The original Breusch–Pagan/Cook–Weisberg version of the test assumes that the e_i are normally distributed under the null hypothesis which implies that the score test statistic S is equal to the model sum of squares from the augmented regression divided by 2. Under the null hypothesis, S has the χ^2 distribution with m degrees of freedom, where m is the number of columns of $\mathbf{z}$.

Koenker (1981) derived a score test of the null hypothesis that $\mathbf{t} = \mathbf{0}$ under the assumption that the e_i are independent and identically distributed (i.i.d.). Koenker showed that $S = N * R^2$ has a large-sample χ^2 distribution with m degrees of freedom, where N is the number of observations and R^2 is the R-squared in the augmented regression and m is the number of columns of $\mathbf{z}$. `estat hettest, iid` produces this version of the test.

Wooldridge (2009) showed that an F test of $\mathbf{t} = \mathbf{0}$ in the augmented regression can also be used under the assumption that the e_i are i.i.d. `estat hettest, fstat` produces this version of the test.

Szroeter's class of tests for homoskedasticity against the alternative that the residual variance increases in some variable x is defined in terms of

$$H = \frac{\sum_{i=1}^{n} h(x_i)e_i^2}{\sum_{i=1}^{n} e_i^2}$$

where $h(x)$ is some weight function that increases in x (Szroeter 1978). H is a weighted average of the $h(x)$, with the squared residuals serving as weights. Under homoskedasticity, H should be approximately equal to the unweighted average of $h(x)$. Large values of H suggest that e_i^2 tends to be large where $h(x)$ is large; that is, the variance indeed increases in x, whereas small values of H suggest that the variance actually decreases in x. `estat szroeter` uses $h(x_i) = \mathrm{rank}(x_i \text{ in } x_1 \ldots x_n)$; see Judge et al. [1985, 452] for details. `estat szroeter` displays a normalized version of H,

$$Q = \sqrt{\frac{6n}{n^2 - 1}}H$$

which is approximately $N(0, 1)$ distributed under the null (homoskedasticity).

`estat hettest` and `estat szroeter` provide adjustments of p-values for multiple testing. The supported methods are described in [R] **test**.

`estat imtest` performs the information matrix test for the regression model, as well as an orthogonal decomposition into tests for heteroskedasticity δ_1, nonnormal skewness δ_2, and nonnormal kurtosis δ_3 (Cameron and Trivedi 1990; Long and Trivedi 1993). The decomposition is obtained via three auxiliary regressions. Let e be the regression residuals, $\widehat{\sigma}^2$ be the maximum likelihood estimate of σ^2 in the regression, n be the number of observations, X be the set of k variables specified with `estat imtest`, and R^2_{un} be the uncentered R^2 from a regression. δ_1 is obtained as nR^2_{un} from a

regression of $e^2 - \widehat{\sigma}^2$ on the cross-products of the variables in X. δ_2 is computed as nR^2_{un} from a regression of $e^3 - 3\widehat{\sigma}^2 e$ on X. Finally, δ_3 is obtained as nR^2_{un} from a regression of $e^4 - 6\widehat{\sigma}^2 e^2 - 3\widehat{\sigma}^4$ on X. δ_1, δ_2, and δ_3 are asymptotically χ^2 distributed with $1/2k(k+1)$, K, and 1 degree of freedom. The information test statistic $\delta = \delta_1 + \delta_2 + \delta_3$ is asymptotically χ^2 distributed with $1/2k(k+3)$ degrees of freedom. White's test for heteroskedasticity is computed as nR^2 from a regression of $\widehat{u}^2$ on X and the cross-products of the variables in X. This test statistic is usually close to δ_1.

`estat vif` calculates the centered variance inflation factor (VIF_c) (Chatterjee and Hadi 2006, 235–239) for x_j, given by

$$\text{VIF}_c(x_j) = \frac{1}{1 - \widehat{R}^2_j}$$

where $\widehat{R}^2_j$ is the square of the centered multiple correlation coefficient that results when x_j is regressed with intercept against all the other explanatory variables.

The uncentered variance inflation factor (VIF_{uc}) (Belsley 1991, 28–29) for x_j is given by

$$\text{VIF}_{uc}(x_j) = \frac{1}{1 - \widetilde{R}^2_j}$$

where $\widetilde{R}^2_j$ is the square of the uncentered multiple correlation coefficient that results when x_j is regressed without intercept against all the other explanatory variables including the constant term.

Acknowledgments

`estat ovtest` and `estat hettest` are based on programs originally written by Richard Goldstein (1991, 1992). `estat imtest`, `estat szroeter`, and the current version of `estat hettest` were written by Jeroen Weesie, Department of Sociology, Utrecht University, The Netherlands; `estat imtest` is based in part on code written by J. Scott Long, Department of Sociology, Indiana University.

Title

regress postestimation time series — Postestimation tools for regress with time series

Description

The following postestimation commands for time series are available for `regress`:

Command	Description
`estat archlm`	test for ARCH effects in the residuals
`estat bgodfrey`	Breusch–Godfrey test for higher-order serial correlation
`estat durbinalt`	Durbin's alternative test for serial correlation
`estat dwatson`	Durbin–Watson d statistic to test for first-order serial correlation

These commands provide regression diagnostic tools specific to time series. You must `tsset` your data before using these commands; see [TS] **tsset**.

`estat archlm` tests for time-dependent volatility. `estat bgodfrey`, `estat durbinalt`, and `estat dwatson` test for serial correlation in the residuals of a linear regression. For non–time-series regression diagnostic tools, see [R] **regress postestimation**.

`estat archlm` performs Engle's Lagrange multiplier (LM) test for the presence of autoregressive conditional heteroskedasticity.

`estat bgodfrey` performs the Breusch–Godfrey test for higher-order serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

`estat durbinalt` performs Durbin's alternative test for serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

`estat dwatson` computes the Durbin–Watson d statistic (Durbin and Watson 1950) to test for first-order serial correlation in the disturbance when all the regressors are strictly exogenous.

Syntax for estat archlm

`estat archlm` [`,` *archlm_options*]

archlm_options	Description
`lags(`*numlist*`)`	test *numlist* lag orders
`force`	allow test after `regress, vce(robust)`

Options for estat archlm

`lags(`*numlist*`)` specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

`force` allows the test to be run after `regress, vce(robust)`. The command will not work if the `vce(cluster` *clustvar*`)` option is specified with `regress`; see [R] **regress**.

Syntax for estat bgodfrey

```
estat bgodfrey [ , bgodfrey_options ]
```

bgodfrey_options	Description
lags(*numlist*)	test *numlist* lag orders
nomiss0	do not use Davidson and MacKinnon's approach
small	obtain p-values using the F or t distribution

Options for estat bgodfrey

lags(*numlist*) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

nomiss0 specifies that Davidson and MacKinnon's approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

small specifies that the p-values of the test statistics be obtained using the F or t distribution instead of the default chi-squared or normal distribution.

Syntax for estat durbinalt

```
estat durbinalt [ , durbinalt_options ]
```

durbinalt_options	Description
lags(*numlist*)	test *numlist* lag orders
nomiss0	do not use Davidson and MacKinnon's approach
robust	compute standard errors using the robust/sandwich estimator
small	obtain p-values using the F or t distribution
force	allow test after `regress, vce(robust)` or after `newey`

Options for estat durbinalt

lags(*numlist*) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

nomiss0 specifies that Davidson and MacKinnon's approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

robust specifies that the Huber/White/sandwich robust estimator of the variance–covariance matrix be used in Durbin's alternative test.

small specifies that the p-values of the test statistics be obtained using the F or t distribution instead of the default chi-squared or normal distribution. This option may not be specified with robust, which always uses an F or t distribution.

`force` allows the test to be run after `regress, vce(robust)` and after `newey` (see [R] **regress** and [TS] **newey**). The command will not work if the `vce(cluster` *clustvar*`)` option is specified with `regress`.

Syntax for estat dwatson

```
estat dwatson
```

Remarks

The Durbin–Watson test is used to determine whether the error term in a linear regression model follows an AR(1) process. For the linear model

$$y_t = \mathbf{x}_t\boldsymbol{\beta} + u_t$$

the AR(1) process can be written as

$$u_t = \rho u_{t-1} + \epsilon_t$$

In general, an AR(1) process requires only that ϵ_t be independent and identically distributed (i.i.d.). The Durbin–Watson test, however, requires ϵ_t to be distributed $N(0, \sigma^2)$ for the statistic to have an exact distribution. Also, the Durbin–Watson test can be applied only when the regressors are strictly exogenous. A regressor x is strictly exogenous if $\text{Corr}(x_s, u_t) = 0$ for all s and t, which precludes the use of the Durbin–Watson statistic with models where lagged values of the dependent variable are included as regressors.

The null hypothesis of the test is that there is no first-order autocorrelation. The Durbin–Watson d statistic can take on values between 0 and 4 and under the null d is equal to 2. Values of d less than 2 suggest positive autocorrelation ($\rho > 0$), whereas values of d greater than 2 suggest negative autocorrelation ($\rho < 0$). Calculating the exact distribution of the d statistic is difficult, but empirical upper and lower bounds have been established based on the sample size and the number of regressors. Extended tables for the d statistic have been published by Savin and White (1977). For example, suppose you have a model with 30 observations and three regressors (including the constant term). For a test of the null hypothesis of no autocorrelation versus the alternative of positive autocorrelation, the lower bound of the d statistic is 1.284, and the upper bound is 1.567 at the 5% significance level. You would reject the null if $d < 1.284$, and you would fail to reject if $d > 1.567$. A value falling within the range (1.284, 1.567) leads to no conclusion about whether or not to reject the null hypothesis.

When lagged dependent variables are included among the regressors, the past values of the error term are correlated with those lagged variables at time t, implying that they are not strictly exogenous regressors. The inclusion of covariates that are not strictly exogenous causes the d statistic to be biased toward the acceptance of the null hypothesis. Durbin (1970) suggested an alternative test for models with lagged dependent variables and extended that test to the more general AR(p) serial correlation process

$$u_t = \rho_1 u_{t-1} + \cdots + \rho_p u_{t-p} + \epsilon_t$$

where ϵ_t is i.i.d. with variance σ^2 but is not assumed or required to be normal for the test.

The null hypothesis of Durbin's alternative test is

$$H_0 : \rho_1 = 0, \ldots, \rho_p = 0$$

and the alternative is that at least one of the ρ's is nonzero. Although the null hypothesis was originally derived for an AR(p) process, this test turns out to have power against MA(p) processes as well. Hence, the actual null of this test is that there is no serial correlation up to order p because the MA(p) and the AR(p) models are locally equivalent alternatives under the null. See Godfrey (1988, 113–115) for a discussion of this result.

Durbin's alternative test is in fact a LM test, but it is most easily computed with a Wald test on the coefficients of the lagged residuals in an auxiliary OLS regression of the residuals on their lags and all the covariates in the original regression. Consider the linear regression model

$$y_t = \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + u_t \tag{1}$$

in which the covariates x_1 through x_k are not assumed to be strictly exogenous and u_t is assumed to be i.i.d. and to have finite variance. The process is also assumed to be stationary. (See Wooldridge [2009] for a discussion of stationarity.) Estimating the parameters in (1) by OLS obtains the residuals $\widehat{u}_t$. Next another OLS regression is performed of $\widehat{u}_t$ on $\widehat{u}_{t-1}, \ldots, \widehat{u}_{t-p}$ and the other regressors,

$$\widehat{u}_t = \gamma_1 \widehat{u}_{t-1} + \cdots + \gamma_p \widehat{u}_{t-p} + \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + \epsilon_t \tag{2}$$

where ϵ_t stands for the random-error term in this auxiliary OLS regression. Durbin's alternative test is then obtained by performing a Wald test that $\gamma_1, \ldots, \gamma_p$ are jointly zero. The test can be made robust to an unknown form of heteroskedasticity by using a robust VCE estimator when estimating the regression in (2). When there are only strictly exogenous regressors and $p = 1$, this test is asymptotically equivalent to the Durbin–Watson test.

The Breusch–Godfrey test is also an LM test of the null hypothesis of no autocorrelation versus the alternative that u_t follows an AR(p) or MA(p) process. Like Durbin's alternative test, it is based on the auxiliary regression (2), and it is computed as NR^2, where N is the number of observations and R^2 is the simple R^2 from the regression. This test and Durbin's alternative test are asymptotically equivalent. The test statistic NR^2 has an asymptotic χ^2 distribution with p degrees of freedom. It is valid with or without the strict exogeneity assumption but is not robust to conditional heteroskedasticity, even if a robust VCE is used when fitting (2).

In fitting (2), the values of the lagged residuals will be missing in the initial periods. As noted by Davidson and MacKinnon (1993), the residuals will not be orthogonal to the other covariates in the model in this restricted sample, which implies that the R^2 from the auxiliary regression will not be zero when the lagged residuals are left out. Hence, Breusch and Godfrey's NR^2 version of the test may overreject in small samples. To correct this problem, Davidson and MacKinnon (1993) recommend setting the missing values of the lagged residuals to zero and running the auxiliary regression in (2) over the full sample used in (1). This small-sample correction has become conventional for both the Breusch–Godfrey and Durbin's alternative test, and it is the default for both commands. Specifying the `nomiss0` option overrides this default behavior and treats the initial missing values generated by regressing on the lagged residuals as missing. Hence, `nomiss0` causes these initial observations to be dropped from the sample of the auxiliary regression.

Durbin's alternative test and the Breusch–Godfrey test were originally derived for the case covered by `regress` without the `vce(robust)` option. However, after `regress, vce(robust)` and `newey`, Durbin's alternative test is still valid and can be invoked if the `robust` and `force` options are specified.

Example 1: tests for serial correlation

Using data from Klein (1950), we first fit an OLS regression of consumption on the government wage bill:

```
. use http://www.stata-press.com/data/r12/klein
. tsset yr
        time variable:  yr, 1920 to 1941
                delta:  1 unit
. regress consump wagegovt
```

Source	SS	df	MS	Number of obs =	22
				F(1, 20) =	17.72
Model	532.567711	1	532.567711	Prob > F =	0.0004
Residual	601.207167	20	30.0603584	R-squared =	0.4697
				Adj R-squared =	0.4432
Total	1133.77488	21	53.9892799	Root MSE =	5.4827

consump	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
wagegovt	2.50744	.5957173	4.21	0.000	1.264796	3.750085
_cons	40.84699	3.192183	12.80	0.000	34.18821	47.50577

If we assume that `wagegov` is a strictly exogenous variable, we can use the Durbin–Watson test to check for first-order serial correlation in the errors.

```
. estat dwatson
Durbin-Watson d-statistic(  2,    22) =  .3217998
```

The Durbin–Watson d statistic, 0.32, is far from the center of its distribution ($d = 2.0$). Given 22 observations and two regressors (including the constant term) in the model, the lower 5% bound is about 0.997, much greater than the computed d statistic. Assuming that `wagegov` is strictly exogenous, we can reject the null of no first-order serial correlation. Rejecting the null hypothesis does not necessarily mean an AR process; other forms of misspecification may also lead to a significant test statistic. If we are willing to assume that the errors follow an AR(1) process and that `wagegov` is strictly exogenous, we could refit the model using `arima` or `prais` and model the error process explicitly; see [TS] **arima** and [TS] **prais**.

If we are not willing to assume that `wagegov` is strictly exogenous, we could instead use Durbin's alternative test or the Breusch–Godfrey to test for first-order serial correlation. Because we have only 22 observations, we will use the `small` option.

```
. estat durbinalt, small
Durbin's alternative test for autocorrelation
```

lags(*p*)	F	df	Prob > F
1	35.035	(1, 19)	0.0000

H0: no serial correlation

```
. estat bgodfrey, small
Breusch-Godfrey LM test for autocorrelation
```

lags(*p*)	F	df	Prob > F
1	14.264	(1, 19)	0.0013

H0: no serial correlation

Both tests strongly reject the null of no first-order serial correlation, so we decide to refit the model with two lags of `consump` included as regressors and then rerun `estat durbinalt` and `estat bgodfrey`. Because the revised model includes lagged values of the dependent variable, the Durbin–Watson test is not applicable.

```
. regress consump wagegovt L.consump L2.consump
```

Source	SS	df	MS		
Model	702.660311	3	234.220104	Number of obs	= 20
Residual	85.1596011	16	5.32247507	F(3, 16)	= 44.01
				Prob > F	= 0.0000
				R-squared	= 0.8919
				Adj R-squared	= 0.8716
Total	787.819912	19	41.4642059	Root MSE	= 2.307

consump	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
wagegovt	.6904282	.3295485	2.10	0.052	-.0081835	1.38904
consump						
L1.	1.420536	.197024	7.21	0.000	1.002864	1.838208
L2.	-.650888	.1933351	-3.37	0.004	-1.06074	-.241036
_cons	9.209073	5.006701	1.84	0.084	-1.404659	19.82281

```
. estat durbinalt, small lags(1/2)
Durbin's alternative test for autocorrelation
```

lags(p)	F	df	Prob > F
1	0.080	(1, 15)	0.7805
2	0.260	(2, 14)	0.7750

H0: no serial correlation

```
. estat bgodfrey, small lags(1/2)
Breusch-Godfrey LM test for autocorrelation
```

lags(p)	F	df	Prob > F
1	0.107	(1, 15)	0.7484
2	0.358	(2, 14)	0.7056

H0: no serial correlation

Although `wagegov` and the constant term are no longer statistically different from zero at the 5% level, the output from `estat durbinalt` and `estat bgodfrey` indicates that including the two lags of `consump` has removed any serial correlation from the errors.

◁

Engle (1982) suggests an LM test for checking for autoregressive conditional heteroskedasticity (ARCH) in the errors. The pth-order ARCH model can be written as

$$\begin{aligned}\sigma_t^2 &= E(u_t^2|u_{t-1},\ldots,u_{t-p}) \\ &= \gamma_0 + \gamma_1 u_{t-1}^2 + \cdots + \gamma_p u_{t-p}^2\end{aligned}$$

To test the null hypothesis of no autoregressive conditional heteroskedasticity (that is, $\gamma_1 = \cdots = \gamma_p = 0$), we first fit the OLS model (1), obtain the residuals $\widehat{u}_t$, and run another OLS regression on the lagged residuals:

$$\widehat{u}_t^2 = \gamma_0 + \gamma_1 \widehat{u}_{t-1}^2 + \cdots + \gamma_p \widehat{u}_{t-p}^2 + \epsilon \tag{3}$$

The test statistic is NR^2, where N is the number of observations in the sample and R^2 is the R^2 from the regression in (3). Under the null hypothesis, the test statistic follows a χ^2_p distribution.

▷ Example 2: estat archlm

We refit the original model that does not include the two lags of `consump` and then use `estat archlm` to see if there is any evidence that the errors are autoregressive conditional heteroskedastic.

```
. regress consump wagegovt
```

Source	SS	df	MS		
Model	532.567711	1	532.567711	Number of obs	= 22
Residual	601.207167	20	30.0603584	F(1, 20)	= 17.72
				Prob > F	= 0.0004
				R-squared	= 0.4697
				Adj R-squared	= 0.4432
Total	1133.77488	21	53.9892799	Root MSE	= 5.4827

consump	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
wagegovt	2.50744	.5957173	4.21	0.000	1.264796	3.750085
_cons	40.84699	3.192183	12.80	0.000	34.18821	47.50577

```
. estat archlm, lags(1 2 3)
LM test for autoregressive conditional heteroskedasticity (ARCH)
```

lags(p)	chi2	df	Prob > chi2
1	5.543	1	0.0186
2	9.431	2	0.0090
3	9.039	3	0.0288

H0: no ARCH effects *vs.* H1: ARCH(*p*) disturbance

`estat archlm` shows the results for tests of ARCH(1), ARCH(2), and ARCH(3) effects, respectively. At the 5% significance level, all three tests reject the null hypothesis that the errors are not autoregressive conditional heteroskedastic. See [TS] **arch** for information on fitting ARCH models.

◁

Saved results

`estat archlm` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(N_gaps)`	number of gaps
`r(k)`	number of regressors		

Macros

`r(lags)`	lag order

Matrices

`r(arch)`	test statistic for each lag order	`r(p)`	two-sided p-values
`r(df)`	degrees of freedom		

`estat bgodfrey` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(N_gaps)`	number of gaps
`r(k)`	number of regressors		

Macros

`r(lags)`	lag order

Matrices

`r(chi2)`	χ^2 statistic for each lag order	`r(p)`	two-sided p-values
`r(F)`	F statistic for each lag order (`small` only)	`r(df)`	degrees of freedom
`r(df_r)`	residual degrees of freedom (`small` only)		

`estat durbinalt` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(N_gaps)`	number of gaps
`r(k)`	number of regressors		

Macros

`r(lags)`	lag order

Matrices

`r(chi2)`	χ^2 statistic for each lag order	`r(p)`	two-sided p-values
`r(F)`	F statistic for each lag order (`small` only)	`r(df)`	degrees of freedom
`r(df_r)`	residual degrees of freedom (`small` only)		

`estat dwatson` saves the following in `r()`:

Scalars

`r(N)`	number of observations	`r(N_gaps)`	number of gaps
`r(k)`	number of regressors	`r(dw)`	Durbin–Watson statistic

Methods and formulas

`estat archlm`, `estat bgodfrey`, `estat durbinalt`, and `estat dwatson` are implemented as ado-files.

Consider the regression

$$y_t = \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + u_t \tag{4}$$

in which some of the covariates are not strictly exogenous. In particular, some of the x_{it} may be lags of the dependent variable. We are interested in whether the u_t are serially correlated.

The Durbin–Watson d statistic reported by `estat dwatson` is

$$d = \frac{\sum_{t=1}^{n-1} (\widehat{u}_{t+1} - \widehat{u}_t)^2}{\sum_{t=1}^{n} \widehat{u}_t^2}$$

where $\widehat{u}_t$ represents the residual of the tth observation.

To compute Durbin's alternative test and the Breusch–Godfrey test against the null hypothesis that there is no pth order serial correlation, we fit the regression in (4), compute the residuals, and then fit the following auxiliary regression of the residuals $\widehat{u}_t$ on p lags of $\widehat{u}_t$ and on all the covariates in the original regression in (4):

$$\widehat{u}_t = \gamma_1 \widehat{u}_{t-1} + \cdots + \gamma_p \widehat{u}_{t-p} + \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + \epsilon \tag{5}$$

Durbin's alternative test is computed by performing a Wald test to determine whether the coefficients of $\widehat{u}_{t-1}, \ldots, \widehat{u}_{t-p}$ are jointly different from zero. By default, the statistic is assumed to be distributed $\chi^2(\mathrm{p})$. When `small` is specified, the statistic is assumed to follow an $F(p, N-p-k)$ distribution. The reported p-value is a two-sided p-value. When `robust` is specified, the Wald test is performed using the Huber/White/sandwich estimator of the variance–covariance matrix, and the test is robust to an unspecified form of heteroskedasticity.

The Breusch–Godfrey test is computed as NR^2, where N is the number of observations in the auxiliary regression (5) and R^2 is the R^2 from the same regression (5). Like Durbin's alternative test, the Breusch–Godfrey test is asymptotically distributed $\chi^2(p)$, but specifying `small` causes the p-value to be computed using an $F(p, N-p-k)$.

By default, the initial missing values of the lagged residuals are replaced with zeros, and the auxiliary regression is run over the full sample used in the original regression of (4). Specifying the `nomiss0` option causes these missing values to be treated as missing values, and the observations are dropped from the sample.

Engle's LM test for ARCH(p) effects fits an OLS regression of $\widehat{u}_t^2$ on $\widehat{u}_{t-1}^2, \ldots, \widehat{u}_{t-p}^2$:

$$\widehat{u}_t^2 = \gamma_0 + \gamma_1 \widehat{u}_{t-1}^2 + \cdots + \gamma_p \widehat{u}_{t-p}^2 + \epsilon$$

The test statistic is nR^2 and is asymptotically distributed $\chi^2(p)$.

Acknowledgment

The original versions of `estat archlm`, `estat bgodfrey`, and `estat durbinalt` were written by Christopher F. Baum, Boston College.

James Durbin (1923–) is a British statistician who was born in Wigan, near Manchester. He studied mathematics at Cambridge and after military service and various research posts joined the London School of Economics in 1950. His many contributions to statistics have centered on serial correlation, time series, sample survey methodology, goodness-of-fit tests, and sample distribution functions, with emphasis on applications in the social sciences.

Geoffrey Stuart Watson (1921–1998) was born in Victoria, Australia, and earned degrees at Melbourne University and North Carolina State University. After a visit to the University of Cambridge, he returned to Australia, working at Melbourne and then the Australian National University. Following periods at Toronto and Johns Hopkins, he settled at Princeton. Throughout his wide-ranging career, he made many notable accomplishments and important contributions, including the Durbin–Watson test for serial correlation, the Nadaraya–Watson estimator in nonparametric regression, and methods for analyzing directional data.

Leslie G. Godfrey (1946–) was born in London and earned degrees at the Universities of Exeter and London. He is now a professor of econometrics at the University of York. His interests center on implementation and interpretation of tests of econometric models, including nonnested models.

Trevor Stanley Breusch (1949–) was born in Queensland and earned degrees at the University of Queensland and Australian National University (ANU). After a post at the University of Southampton, he returned to work at ANU. His background is in econometric methods and his recent interests include political values and social attitudes, earnings and income, and measurement of underground economic activity.

Title

#review — Review previous commands

Syntax

```
#review  [ #1 [ #2 ] ]
```

Description

The `#review` command displays the last few lines typed at the terminal.

Remarks

`#review` (pronounced *pound-review*) is a Stata preprocessor command. `#`*command*s do not generate a return code or generate ordinary Stata errors. The only error message associated with `#`*command*s is "unrecognized #command".

The `#review` command displays the last few lines typed at the terminal. If no arguments follow `#review`, the last five lines typed at the terminal are displayed. The first argument specifies the number of lines to be reviewed, so `#review 10` displays the last 10 lines typed. The second argument specifies the number of lines to be displayed, so `#review 10 5` displays five lines, starting at the 10th previous line.

Stata reserves a buffer for `#review` lines and stores as many previous lines in the buffer as will fit, rolling out the oldest line to make room for the newest. Requests to `#review` lines no longer stored will be ignored. Only lines typed at the terminal are placed in the `#review` buffer. See [U] **10.5 Editing previous lines in Stata**.

▷ Example 1

Typing `#review` by itself will show the last five lines you typed at the terminal:

```
. #review
5 use mydata
4 * comments go into the #review buffer, too
3 describe
2 tabulate marriage educ [freq=number]
1 tabulate marriage educ [freq=number], chi2
. _
```

Typing `#review 15 2` shows the 15th and 14th previous lines:

```
. #review 15 2
15 replace x=. if x<200
14 summarize x
. _
```

◁

Title

roc — Receiver operating characteristic (ROC) analysis

Description

ROC analysis quantifies the accuracy of diagnostic tests or other evaluation modalities used to discriminate between two states or conditions, which are here referred to as normal and abnormal or control and case. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known normal and abnormal subjects. For this reason, we often refer to the diagnostic test as a classifier. The analysis uses the ROC curve, a graph of the sensitivity versus 1 − specificity of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus the sensitivity is the true-positive rate, and the specificity is the true-negative rate.

There are six ROC commands:

Command	Entry	Description
`roccomp`	[R] **roccomp**	Tests of equality of ROC areas
`rocgold`	[R] **roccomp**	Tests of equality of ROC areas against a standard ROC curve
`rocfit`	[R] **rocfit**	Parametric ROC models
`rocreg`	[R] **rocreg**	Nonparametric and parametric ROC regression models
`rocregplot`	[R] **rocregplot**	Plot marginal and covariate-specific ROC curves
`roctab`	[R] **roctab**	Nonparametric ROC analysis

Postestimation commands are available after `rocfit` and `rocreg`; see [R] **rocfit postestimation** and [R] **rocreg postestimation**.

Both nonparametric and parametric (semiparametric) methods have been suggested for generating the ROC curve. The `roctab` command performs nonparametric ROC analysis for a single classifier. `roccomp` extends the nonparametric ROC analysis function of `roctab` to situations where we have multiple diagnostic tests of interest to be compared and tested. The `rocgold` command also provides ROC analysis for multiple classifiers. `rocgold` compares each classifier's ROC curve to a "gold standard" ROC curve and makes adjustments for multiple comparisons in the analysis. Both `rocgold` and `roccomp` also allow parametric estimation of the ROC curve through a binormal fit. In a binormal fit, both the control and the case populations are normal.

The `rocfit` command also estimates the ROC curve of a classifier through a binormal fit. Unlike `roctab`, `roccomp`, and `rocgold`, `rocfit` is an estimation command. In postestimation, graphs of the ROC curve and confidence bands can be produced. Additional tests on the parameters can also be conducted.

ROC analysis can be interpreted as a two-stage process. First, the control distribution of the classifier is estimated, assuming a normal model or using a distribution-free estimation technique. The classifier is standardized using the control distribution to 1 − percentile value, the false-positive rate. Second, the ROC curve is estimated as the case distribution of the standardized classifier values.

Covariates may affect both stages of ROC analysis. The first stage may be affected, yielding a covariate-adjusted ROC curve. The second stage may also be affected, producing multiple covariate-specific ROC curves.

The `rocreg` command performs ROC analysis under both types of covariate effects. Both parametric (semiparametric) and nonparametric methods may be used by `rocreg`. Like `rocfit`, `rocreg` is an estimation command and provides many postestimation capabilities.

The global performance of a diagnostic test is commonly summarized by the area under the ROC curve (AUC). This area can be interpreted as the probability that the result of a diagnostic test of a randomly selected abnormal subject will be greater than the result of the same diagnostic test from a randomly selected normal subject. The greater the AUC, the better the global performance of the diagnostic test. Each of the ROC commands provides computation of the AUC.

Citing a lack of clinical relevance for the AUC, other ROC summary measures have been suggested. These include the partial area under the ROC curve for a given false-positive rate t [pAUC(t)]. This is the area under the ROC curve from the false-positive rate of 0 to t. The ROC value at a particular false-positive rate and the false-positive rate for a particular ROC value are also useful summary measures for the ROC curve. These three measures are directly estimated by `rocreg` during the model fit or postestimation stages. Point estimates of ROC value are computed by the other ROC commands, but no standard errors are reported.

See Pepe (2003) for a discussion of ROC analysis. Pepe has posted Stata datasets and programs used to reproduce results presented in the book (http://www.stata.com/bookstore/pepe.html).

Title

roccomp — Tests of equality of ROC areas

Syntax

Test equality of ROC areas

`roccomp` *refvar classvar* [*classvars*] [*if*] [*in*] [*weight*] [`,` *roccomp_options*]

Test equality of ROC area against a standard ROC curve

`rocgold` *refvar goldvar classvar* [*classvars*] [*if*] [*in*] [*weight*] [`,` *rocgold_options*]

roccomp_options	Description
Main	
`by(`*varname*`)`	split into groups by variable
`test(`*matname*`)`	use contrast matrix for comparing ROC areas
`graph`	graph the ROC curve
`norefline`	suppress plotting the 45-degree reference line
`separate`	place each ROC curve on its own graph
`summary`	report the area under the ROC curve
`binormal`	estimate areas by using binormal distribution assumption
`line#opts(`*cline_options*`)`	affect rendition of the #th binormal fit line
`level(#)`	set confidence level; default is `level(95)`
Plot	
`plot#opts(`*plot_options*`)`	affect rendition of the #th ROC curve
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

`fweights` are allowed; see [U] **11.1.6 weight**.

rocgold_options	Description
Main	
`sidak`	adjust the significance probability by using Šidák's method
`test(`*matname*`)`	use contrast matrix for comparing ROC areas
`graph`	graph the ROC curve
`norefline`	suppress plotting the 45-degree reference line
`separate`	place each ROC curve on its own graph
`summary`	report the area under the ROC curve
`binormal`	estimate areas by using binormal distribution assumption
`line#opts(`*cline_options*`)`	affect rendition of the #th binormal fit line
`level(#)`	set confidence level; default is `level(95)`
Plot	
`plot#opts(`*plot_options*`)`	affect rendition of the #th ROC curve; plot 1 is the "gold standard"
Reference line	
`rlopts(`*cline_options*`)`	affect rendition of the reference line

twoway_options	any options other than `by()` documented in [G-3] ***twoway_options***

`fweights` are allowed; see [U] **11.1.6 weight**.

plot_options	Description
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
cline_options	change the look of the line

Menu

roccomp

Statistics > Epidemiology and related > ROC analysis > Test equality of two or more ROC areas

rocgold

Statistics > Epidemiology and related > ROC analysis > Test equality of ROC area against gold standard

Description

The above commands are used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be at least ordinal, with higher values indicating higher risk.

`roccomp` tests the equality of two or more ROC areas obtained from applying two or more test modalities to the same sample or to independent samples. `roccomp` expects the data to be in wide form when comparing areas estimated from the same sample and in long form for areas estimated from independent samples.

`rocgold` independently tests the equality of the ROC area of each of several test modalities, specified by *classvar*, against a "gold standard" ROC curve, *goldvar*. For each comparison, `rocgold` reports the raw and the Bonferroni-adjusted significance probability. Optionally, Šidák's adjustment for multiple comparisons can be obtained.

See [R] **rocfit** and [R] **rocreg** for commands that fit maximum-likelihood ROC models.

Options

Main

`by(`*varname*`)` (`roccomp` only) is required when comparing independent ROC areas. The `by()` variable identifies the groups to be compared.

`sidak` (`rocgold` only) requests that the significance probability be adjusted for the effect of multiple comparisons by using Šidák's method. Bonferroni's adjustment is reported by default.

`test(`*matname*`)` specifies the contrast matrix to be used when comparing ROC areas. By default, the null hypothesis that all areas are equal is tested.

`graph` produces graphical output of the ROC curve.

`norefline` suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

`separate` is meaningful only with `roccomp` and specifies that each ROC curve be placed on its own graph rather than one curve on top of the other.

`summary` reports the area under the ROC curve, its standard error, and its confidence interval. This option is needed only when also specifying `graph`.

`binormal` specifies that the areas under the ROC curves to be compared should be estimated using the binormal distribution assumption. By default, areas to be compared are computed using the trapezoidal rule.

`line#opts(`*cline_options*`)` affects the rendition of the line representing the #th ROC curve drawn using the binormal distribution assumption; see [G-3] ***cline_options***. These lines are drawn only if the `binormal` option is specified.

`level(#)` specifies the confidence level, as a percentage, for the confidence intervals. The default is `level(95)` or as set by `set level`; see [R] **level**.

Plot

`plot#opts(`*plot_options*`)` affects the rendition of the #th ROC curve—the curve's plotted points connected by lines. The *plot_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] ***marker_options***, [G-3] ***marker_label_options***, and [G-3] ***cline_options***.

For `rocgold`, `plot1opts()` are applied to the ROC for the gold standard.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line; see [G-3] ***cline_options***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***. These include options for titling the graph (see [G-3] ***title_options***), options for saving the graph to disk (see [G-3] ***saving_option***), and the `by()` option (see [G-3] ***by_option***).

Remarks

Remarks are presented under the following headings:

Introduction
Comparing areas under the ROC curve
Correlated data
Independent data
Comparing areas with a gold standard

Introduction

`roccomp` provides comparison of the ROC curves of multiple classifiers. `rocgold` compares the ROC curves of multiple classifiers with a single "gold standard" classifier. Adjustment of inference for multiple comparisons is also provided by `rocgold`.

See Pepe (2003) for a discussion of ROC analysis. Pepe has posted Stata datasets and programs used to reproduce results presented in the book (http://www.stata.com/bookstore/pepe.html).

Comparing areas under the ROC curve

The area under multiple ROC curves can be compared by using `roccomp`. The command syntax is slightly different if the ROC curves are correlated (that is, different diagnostic tests are applied to the same sample) or independent (that is, diagnostic tests are applied to different samples).

Correlated data

▷ Example 1

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms' modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 = definitely normal, 2 = probably normal, 3 = possibly normal, 4 = possibly abnormal, 5 = probably abnormal, and 6 = definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first 7 observations:

```
. use http://www.stata-press.com/data/r12/ct
. list in 1/7, sep(0)
```

	mod1	mod2	status
1.	2	1	0
2.	5	5	1
3.	2	1	0
4.	2	3	0
5.	5	6	1
6.	2	2	0
7.	3	2	0

The data are in wide form, which is required when dealing with correlated data. Each observation corresponds to one phantom. The variable `mod1` identifies the rating assigned for the first modality, and `mod2` identifies the rating assigned for the second modality. The true status of the phantoms is given by `status=0` if they are normal and `status=1` if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

We plot the two ROC curves and compare their areas.

```
. roccomp status mod1 mod2, graph summary
```

	Obs	ROC Area	Std. Err.	−Asymptotic Normal− [95% Conf.	Interval]
mod1	112	0.8828	0.0317	0.82067	0.94498
mod2	112	0.9302	0.0256	0.88005	0.98042

```
Ho: area(mod1) = area(mod2)
    chi2(1) =     2.31       Prob>chi2 =   0.1282
```

By default, `roccomp`, with the `graph` option specified, plots the ROC curves on the same graph. Optionally the curves can be plotted side by side, each on its own graph, by also specifying `separate`.

For each curve, `roccomp` reports summary statistics and provides a test for the equality of the area under the curves, using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988).

Although the area under the ROC curve for modality 2 is larger than that of modality 1, the chi-squared test yielded a significance probability of 0.1282, suggesting that there is no significant difference between these two areas.

The `roccomp` command can also be used to compare more than two ROC areas. To illustrate this, we modified the previous dataset by including a fictitious third modality.

```
. use http://www.stata-press.com/data/r12/ct2
. roccomp status mod1 mod2 mod3, graph summary
```

	Obs	ROC Area	Std. Err.	−Asymptotic Normal− [95% Conf.	Interval]
mod1	112	0.8828	0.0317	0.82067	0.94498
mod2	112	0.9302	0.0256	0.88005	0.98042
mod3	112	0.9240	0.0241	0.87670	0.97132

```
Ho: area(mod1) = area(mod2) = area(mod3)
    chi2(2) =     6.54       Prob>chi2 =   0.0381
```

By default, `roccomp` tests whether the areas under the ROC curves are all equal. Other comparisons can be tested by creating a contrast matrix and specifying `test(`*matname*`)`, where *matname* is the name of the contrast matrix.

For example, assume that we are interested in testing whether the area under the ROC for `mod1` is equal to that of `mod3`. To do this, we can first create an appropriate contrast matrix and then specify its name with the `test()` option.

Of course, this is a trivial example because we could have just specified

```
. roccomp status mod1 mod3
```

without including `mod2` to obtain the same test results. However, for illustration, we will continue with this example.

The contrast matrix must have its number of columns equal to the number of *classvars* (that is, the total number of ROC curves) and a number of rows less than or equal to the number of *classvars*, and the elements of each row must add to zero.

```
. matrix C=(1,0,-1)
. roccomp status mod1 mod2 mod3, test(C)
                              ROC                    -Asymptotic Normal--
                    Obs       Area     Std. Err.      [95% Conf. Interval]
---------------------------------------------------------------------------
mod1                112     0.8828       0.0317        0.82067     0.94498
mod2                112     0.9302       0.0256        0.88005     0.98042
mod3                112     0.9240       0.0241        0.87670     0.97132
---------------------------------------------------------------------------
Ho: Comparison as defined by contrast matrix: C
    chi2(1) =     5.25       Prob>chi2 =    0.0220
```

Although all three areas are reported, the comparison is made using the specified contrast matrix.

Perhaps more interesting would be a comparison of the area from `mod1` and the average area of `mod2` and `mod3`.

```
. matrix C=(1,-.5,-.5)
. roccomp status mod1 mod2 mod3, test(C)
                              ROC                    -Asymptotic Normal--
                    Obs       Area     Std. Err.      [95% Conf. Interval]
---------------------------------------------------------------------------
mod1                112     0.8828       0.0317        0.82067     0.94498
mod2                112     0.9302       0.0256        0.88005     0.98042
mod3                112     0.9240       0.0241        0.87670     0.97132
---------------------------------------------------------------------------
Ho: Comparison as defined by contrast matrix: C
    chi2(1) =     3.43       Prob>chi2 =    0.0642
```

Other contrasts could be made. For example, we could test if `mod3` is different from at least one of the other two by first creating the following contrast matrix:

```
. matrix C=(-1, 0, 1 \ 0, -1, 1)
. matrix list C
C[2,3]
    c1  c2  c3
r1  -1   0   1
r2   0  -1   1
```

◁

Independent data

▷ Example 2

In example 1, we noted that because each test modality was applied to the same sample of phantoms, the classification outcomes were correlated. Now assume that we have collected the same data presented by Hanley and McNeil (1983), except that we applied the first test modality to one sample of phantoms and the second test modality to a different sample of phantoms. The resulting measurements are now considered independent.

Here are a few of the observations.

```
. use http://www.stata-press.com/data/r12/ct3
. list in 1/7, sep(0)
```

	pop	status	rating	mod
1.	12	0	1	1
2.	31	0	1	2
3.	1	1	1	1
4.	3	1	1	2
5.	28	0	2	1
6.	19	0	2	2
7.	3	1	2	1

The data are in long form, which is required when dealing with independent data. The data consist of 24 observations: 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the first modality, and similarly 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the second modality. The number of phantoms corresponding to each observation is given by the `pop` variable. Once again we have frequency-weighted data. The variable `mod` identifies the modality, and `rating` is the assigned classification.

We can better view our data by using the `table` command.

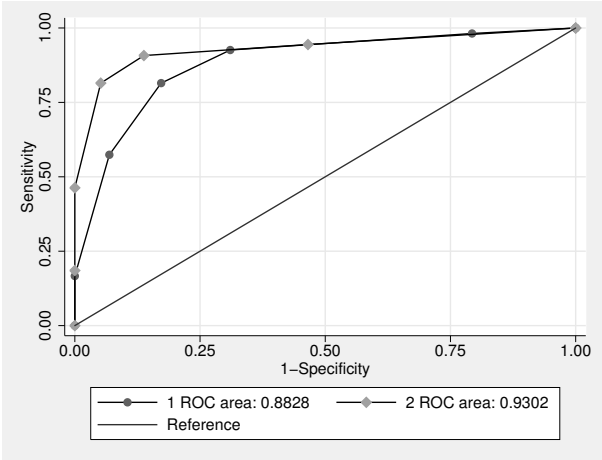
```
. table status rating [fw=pop], by(mod) row col
```

mod and status	rating						
	1	2	3	4	5	6	Total
1							
0	12	28	8	6	4		58
1	1	3	6	13	22	9	54
Total	13	31	14	19	26	9	112
2							
0	31	19	5	3			58
1	3	2	5	19	15	10	54
Total	34	21	10	22	15	10	112

The `status` variable indicates the true status of the phantoms: `status` $= 0$ if they are normal and `status` $= 1$ if they are abnormal.

We now compare the areas under the two ROC curves.

```
. roccomp status rating [fw=pop], by(mod) graph summary
```



mod	Obs	ROC Area	Std. Err.	-Asymptotic Normal— [95% Conf.	Interval]
1	112	0.8828	0.0317	0.82067	0.94498
2	112	0.9302	0.0256	0.88005	0.98042

```
Ho: area(1) = area(2)
    chi2(1) =     1.35       Prob>chi2 =   0.2447
```

Comparing areas with a gold standard

The area under multiple ROC curves can be compared with a gold standard using `rocgold`. The command syntax is similar to that of `roccomp`. The tests are corrected for the effect of multiple comparisons.

▷ Example 3

We will use the same data (presented by Hanley and McNeil [1983]) as in the `roccomp` examples. Let's assume that the first modality is considered to be the standard against which both the second and third modalities are compared.

We want to plot and compare both the areas of the ROC curves of `mod2` and `mod3` with `mod1`. Because we consider `mod1` to be the gold standard, it is listed first after the reference variable in the `rocgold` command line.

```
. use http://www.stata-press.com/data/r12/ct2
. rocgold status mod1 mod2 mod3, graph summary
```

	ROC Area	Std. Err.	chi2	df	Pr>chi2	Bonferroni Pr>chi2
mod1 (standard)	0.8828	0.0317				
mod2	0.9302	0.0256	2.3146	1	0.1282	0.2563
mod3	0.9240	0.0241	5.2480	1	0.0220	0.0439

Equivalently, we could have done this in two steps by using the `roccomp` command.

```
. roccomp status mod1 mod2, graph summary
. roccomp status mod1 mod3, graph summary
```

◁

Saved results

`roccomp` saves the following in `r()`:

Scalars

`r(N_g)`	number of groups	`r(df)`	χ^2 degrees of freedom
`r(p)`	significance probability	`r(chi2)`	χ^2

Matrices

`r(V)`	variance–covariance matrix

`rocgold` saves the following in `r()`:

Scalars

`r(N_g)`	number of groups

Matrices

`r(V)`	variance–covariance matrix	`r(p)`	significance-probability vector
`r(chi2)`	χ^2 vector	`r(p_adj)`	adjusted significance-probability vector
`r(df)`	χ^2 degrees-of-freedom vector		

Methods and formulas

`roccomp` and `rocgold` are implemented as ado-files.

Assume that we applied a diagnostic test to each of N_n normal and N_a abnormal subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let $\widehat{\theta}$ be the estimated area under the curve, and let $X_i, i = 1, 2, \ldots, N_a$ and $Y_j, j = 1, 2, \ldots, N_n$ be the values of the diagnostic test for the abnormal and normal subjects, respectively.

Areas under ROC curves are compared using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988). Let $\widehat{\theta} = (\widehat{\theta^1}, \widehat{\theta^2}, \ldots, \widehat{\theta^k})$ be a vector representing the areas under k ROC curves. See *Methods and formulas* in [R] **roctab** for the definition of these area estimates.

For the rth area, define

$$V_{10}^r(X_i) = \frac{1}{N_n} \sum_{j=1}^{N_n} \psi(X_i^r, Y_j^r)$$

and for each normal subject, j, define

$$V_{01}^r(Y_j) = \frac{1}{N_a} \sum_{i=1}^{N_a} \psi(X_i^r, Y_j^r)$$

where

$$\psi(X^r, Y^r) = \begin{cases} 1 & Y^r < X^r \\ \frac{1}{2} & Y^r = X^r \\ 0 & Y^r > X^r \end{cases}$$

Define the $k \times k$ matrix $\mathbf{S_{10}}$ such that the (r, s)th element is

$$S_{10}^{r,s} = \frac{1}{N_a - 1} \sum_{i=1}^{N_a} \{V_{10}^r(X_i) - \widehat{\theta^r}\}\{V_{10}^s(X_i) - \widehat{\theta^s}\}$$

and $\mathbf{S_{01}}$ such that the (r, s)th element is

$$S_{01}^{r,s} = \frac{1}{N_n - 1} \sum_{j=1}^{N_n} \{V_{01}^r(Y_i) - \widehat{\theta^r}\}\{V_{01}^s(Y_i) - \widehat{\theta^s}\}$$

Then the covariance matrix is

$$S = \frac{1}{N_a} S_{10} + \frac{1}{N_n} S_{01}$$

Let $\mathbf{L}$ be a contrast matrix defining the comparison, so that

$$(\widehat{\theta} - \theta)' \mathbf{L}' \left(\mathbf{LSL}'\right)^{-1} \mathbf{L} (\widehat{\theta} - \theta)$$

has a chi-squared distribution with degrees of freedom equal to the rank of $\mathbf{LSL}'$.

Title

rocfit — Parametric ROC models

Syntax

`rocfit` *refvar classvar* [*if*] [*in*] [*weight*] [`,` *rocfit_options*]

rocfit_options	Description
Model	
`continuous(#)`	divide *classvar* into # groups of approximately equal length
`generate(`*newvar*`)`	create *newvar* containing classification groups
SE	
`vce(`*vcetype*`)`	*vcetype* may be `oim` or `opg`
Reporting	
`level(#)`	set confidence level; default is `level(95)`
Maximization	
maximize_options	control the maximization process; seldom used

`fweights` are allowed; see [U] **11.1.6 weight**.
See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Epidemiology and related > ROC analysis > Parametric ROC analysis without covariates

Description

`rocfit` fits maximum-likelihood ROC models assuming a binormal distribution of the latent variable.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be at least ordinal, with higher values indicating higher risk.

See [R] **roc** for other commands designed to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

Options

Model

`continuous(#)` specifies that the continuous *classvar* be divided into # groups of approximately equal length. This option is required when *classvar* takes on more than 20 distinct values.

`continuous(.)` may be specified to indicate that *classvar* be used as it is, even though it could have more than 20 distinct values.

`generate(`*newvar*`)` specifies the new variable that is to contain the values indicating the groups produced by `continuous(#)`. `generate()` may be specified only with `continuous()`.

SE

`vce(`*vcetype*`)` specifies the type of standard error reported. *vcetype* may be either `oim` or `opg`; see [R] ***vce_option***.

Reporting

`level(#)`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

Remarks

Dorfman and Alf (1969) developed a generalized approach for obtaining maximum likelihood estimates of the parameters for a smooth fitting ROC curve. The most commonly used method for ordinal data, and the one implemented here, is based upon the binormal model; see Pepe (2003), Pepe, Longton, and Janes (2009), and Janes, Longton, and Pepe (2009) for methods of ROC analysis for continuous data, including methods for adjusting for covariates.

The model assumes the existence of an unobserved, continuous, latent variable that is normally distributed (perhaps after a monotonic transformation) in both the normal and abnormal populations with means μ_n and μ_a and variances σ_n^2 and σ_a^2, respectively. The model further assumes that the K categories of the rating variable result from partitioning the unobserved latent variable by $K-1$ fixed boundaries. The method fits a straight line to the empirical ROC points plotted using normal probability scales on both axes. Maximum likelihood estimates of the line's slope and intercept and the $K-1$ boundaries are obtained simultaneously. See *Methods and formulas* for details.

The intercept from the fitted line is a measurement of $(\mu_a - \mu_n)/\sigma_a$, and the slope measures σ_n/σ_a.

Thus the intercept is the standardized difference between the two latent population means, and the slope is the ratio of the two standard deviations. The null hypothesis that there is no difference between the two population means is evaluated by testing that the intercept $= 0$, and the null hypothesis that the variances in the two populations are equal is evaluated by testing that the slope $= 1$.

▷ Example 1

We use Hanley and McNeil's (1982) dataset, described in example 1 of [R] **roctab**, to fit a smooth ROC curve assuming a binormal model.

```
. use http://www.stata-press.com/data/r12/hanley
. rocfit disease rating
Fitting binormal model:
Iteration 0:   log likelihood = -123.68069
Iteration 1:   log likelihood = -123.64867
Iteration 2:   log likelihood = -123.64855
Iteration 3:   log likelihood = -123.64855
Binormal model of disease on rating              Number of obs   =       109
Goodness-of-fit chi2(2) =        0.21
Prob > chi2             =      0.9006
Log likelihood          =  -123.64855
```

	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]

	Indices from binormal fit			
Index	Estimate	Std. Err.	[95% Conf.	Interval]
ROC area	0.911331	0.029506	0.853501	0.969161
delta(m)	2.323671	0.502370	1.339044	3.308298
d(e)	1.934361	0.257187	1.430284	2.438438
d(a)	1.907771	0.259822	1.398530	2.417012

```
(*) z test for slope==1
```

`rocfit` outputs the MLE for the intercept and slope of the fitted regression line along with, here, four boundaries (because there are five ratings) labeled `/cut1` through `/cut4`. Also `rocfit` computes and reports four indices based on the fitted ROC curve: the area under the curve (labeled `ROC area`), $\delta(m)$ (labeled `delta(m)`), d_e (labeled `d(e)`), and d_a (labeled `d(a)`). More information about these indices can be found in *Methods and formulas* and in Erdreich and Lee (1981).

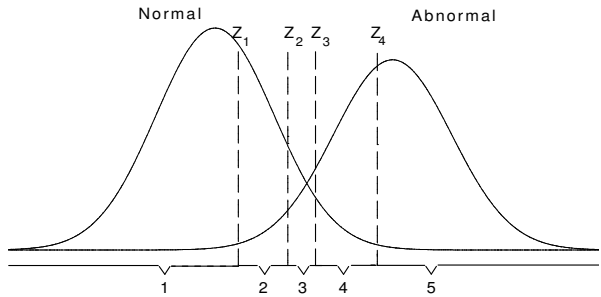
Methods and formulas

`rocfit` is implemented as an ado-file.

Dorfman and Alf (1969) developed a general procedure for obtaining maximum likelihood estimates of the parameters of a smooth-fitting ROC curve. The most common method, and the one implemented in Stata, is based upon the binormal model.

The model assumes that there is an unobserved continuous latent variable that is normally distributed in both the normal and abnormal populations. The idea is better explained with the following illustration:



The latent variable is assumed to be normally distributed for both the normal and abnormal subjects, perhaps after a monotonic transformation, with means μ_n and μ_a and variances σ_n^2 and σ_a^2, respectively.

This latent variable is assumed to be partitioned into the k categories of the rating variable by $k-1$ fixed boundaries. In the above figure, the $k=5$ categories of the rating variable identified on the bottom result from the partition of the four boundaries Z_1 through Z_4.

Let R_j for $j=1,2,\ldots,k$ indicate the categories of the rating variable, let $i=1$ if the subject belongs to the normal group, and let $i=2$ if the subject belongs to the abnormal group.

Then

$$p(R_j|i=1) = F(Z_j) - F(Z_{j-1})$$

where $Z_k = (x_k - \mu_n)/\sigma_n$, F is the cumulative normal distribution, $F(Z_0)=0$, and $F(Z_k)=1$. Also,

$$p(R_j|i=2) = F(bZ_j - a) - F(bZ_{j-1} - a)$$

where $b = \sigma_n/\sigma_a$ and $a = (\mu_a - \mu_n)/\sigma_a$.

The parameters a, b and the $k-1$ fixed boundaries Z_j are simultaneously estimated by maximizing the log-likelihood function

$$\log L = \sum_{i=1}^{2}\sum_{j=1}^{k} r_{ij}\log\{p(R_j|i)\}$$

where r_{ij} is the number of R_js in group i.

The area under the fitted ROC curve is computed as

$$\Phi\left(\frac{a}{\sqrt{1+b^2}}\right)$$

where Φ is the standard normal cumulative distribution function.

Point estimates for the ROC curve indices are as follows:

$$\delta(m) = \frac{a}{b} \qquad d_e = \frac{2a}{b+1} \qquad d_a = \frac{a\sqrt{2}}{\sqrt{1+b^2}}$$

Variances for these indices are computed using the delta method.

The $\delta(m)$ estimates $(\mu_a - \mu_n)/\sigma_n$, d_e estimates $2(\mu_a - \mu_n)/(\sigma_a - \sigma_n)$, and d_a estimates $\sqrt{2}(\mu_a - \mu_n)/(\sigma_a^2 - \sigma_n^2)^2$.

Simultaneous confidence bands for the entire curve are obtained, as suggested by Ma and Hall (1993), by first obtaining Working–Hotelling (1929) confidence bands for the fitted straight line in normal probability coordinates and then transforming them back to ROC coordinates.

Title

rocfit postestimation — Postestimation tools for rocfit

Description

The following command is of special interest after `rocfit`:

Command	Description
`rocplot`	plot the fitted ROC curve and simultaneous confidence bands

For information about `rocplot`, see below.

The following standard postestimation commands are also available:

Command	Description
`estat`	AIC, BIC, VCE, and estimation sample summary
`estimates`	cataloging estimation results
* `lincom`	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* `test`	Wald tests of simple and composite linear hypotheses

*See *Using lincom and test* below.

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation command

`rocplot` plots the fitted ROC curve and simultaneous confidence bands.

Syntax for rocplot

```
rocplot [ , rocplot_options ]
```

rocplot_options	Description
Main	
confband	display confidence bands
norefline	suppress plotting the reference line
level(#)	set confidence level; default is level(95)
Plot	
plotopts(*plot_options*)	affect rendition of the ROC points
Fit line	
lineopts(*cline_options*)	affect rendition of the fitted ROC line
CI plot	
ciopts(*area_options*)	affect rendition of the confidence bands
Reference line	
rlopts(*cline_options*)	affect rendition of the reference line
Add plots	
addplot(*plot*)	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
twoway_options	any options other than by() documented in [G-3] ***twoway_options***

plot_options	Description
marker_options	change look of markers (color, size, etc.)
marker_label_options	add marker labels; change look or position
cline_options	change the look of the line

Menu

Statistics > Epidemiology and related > ROC analysis > ROC curves after rocfit

Options for rocplot

Main

confband specifies that simultaneous confidence bands be plotted around the ROC curve.

norefline suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

level(#) specifies the confidence level, as a percentage, for the confidence bands. The default is level(95) or as set by set level; see [R] **level**.

Plot

`plotopts(`*plot_options*`)` affects the rendition of the plotted ROC points, including the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected. For the full list of available *plot_options*, see [G-3] ***marker_options***, [G-3] ***marker_label_options***, and [G-3] ***cline_options***.

Fit line

`lineopts(`*cline_options*`)` affects the rendition of the fitted ROC line; see [G-3] ***cline_options***.

CI plot

`ciopts(`*area_options*`)` affects the rendition of the confidence bands; see [G-3] ***area_options***.

Reference line

`rlopts(`*cline_options*`)` affects the rendition of the reference line; see [G-3] ***cline_options***.

Add plots

`addplot(`*plot*`)` provides a way to add other plots to the generated graph. See [G-3] ***addplot_option***.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] ***twoway_options***, excluding `by()`. These include options for titling the graph (see [G-3] ***title_options***) and for saving the graph to disk (see [G-3] ***saving_option***).

Remarks

Remarks are presented under the following headings:

Using lincom and test
Using rocplot

Using lincom and test

`intercept`, `slope`, and `cut#`, shown in example 1 of [R] **rocfit**, are equation names and not variable names, so they need to be referenced as described in *Special syntaxes after multiple-equation estimation* of [R] **test**. For example, instead of typing

```
. test intercept
intercept not found
r(111);
```

you should type

```
. test [intercept]_cons
 ( 1)  [intercept]_cons = 0
           chi2(  1) =   28.48
         Prob > chi2 =    0.0000
```

Using rocplot

▷ Example 1

In example 1 of [R] **rocfit**, we fit a ROC curve by typing `rocfit disease rating`.

In the output table for our model, we are testing whether the variances of the two latent populations are equal by testing that the slope = 1.

We plot the fitted ROC curve.

```
. rocplot, confband
```

Title

rocreg — Receiver operating characteristic (ROC) regression

Syntax

Perform nonparametric analysis of ROC curve under covariates, using bootstrap

```
rocreg refvar classvar [classvars] [if] [in] [, np_options boot_options]
```

Perform parametric analysis of ROC curve under covariates, using bootstrap

```
rocreg refvar classvar [classvars] [if] [in], probit
    [probit_options boot_options]
```

Perform parametric analysis of ROC curve under covariates, using maximum likelihood

```
rocreg refvar classvar [classvars] [if] [in] [weight], probit ml
    [probit_ml_options]
```

np_options	Description
Model	
`auc`	estimate total area under the ROC curve; the default
`roc(`*numlist*`)`	estimate ROC for given false-positive rates
`invroc(`*numlist*`)`	estimate false-positive rates for given ROC values
`pauc(`*numlist*`)`	estimate partial area under the ROC curve (pAUC) up to each false-positive rate
`cluster(`*varname*`)`	variable identifying resampling clusters
`ctrlcov(`*varlist*`)`	adjust control distribution for covariates in *varlist*
`ctrlmodel(strata|linear)`	stratify or regress on covariates; default is `ctrlmodel(strata)`
`pvc(empirical|normal)`	use empirical or normal distribution percentile value estimates; default is `pvc(empirical)`
`tiecorrected`	adjust for tied observations; not allowed with `pvc(normal)`
Reporting	
`level(#)`	set confidence level; default is `level(95)`

probit_options	Description
Model	
* probit	fit the probit model
roccov(*varlist*)	covariates affecting ROC curve
fprpts(#)	number of false-positive rate points to use in fitting ROC curve; default is fprpts(10)
ctrlfprall	fit ROC curve at each false-positive rate in control population
cluster(*varname*)	variable identifying resampling clusters
ctrlcov(*varlist*)	adjust control distribution for covariates in *varlist*
ctrlmodel(strata | linear)	stratify or regress on covariates; default is ctrlmodel(strata)
pvc(empirical | normal)	use empirical or normal distribution percentile value estimates; default is pvc(empirical)
tiecorrected	adjust for tied observations; not allowed with pvc(normal)
Reporting	
level(#)	set confidence level; default is level(95)

*probit is required.

probit_ml_options	Description
Model	
* probit	fit the probit model
* ml	fit the probit model by maximum likelihood estimation
roccov(*varlist*)	covariates affecting ROC curve
cluster(*varname*)	variable identifying clusters
ctrlcov(*varlist*)	adjust control distribution for covariates in *varlist*
Reporting	
level(#)	set confidence level; default is level(95)
display_options	control column formats, line width, and display of omitted variables
Maximization	
maximize_options	control the maximization process; seldom used

*probit and ml are required.

fweights, iweights, and pweights are allowed with maximum likelihood estimation; see [U] **11.1.6 weight**.

boot_options	Description
Bootstrap	
nobootstrap	do not perform bootstrap, just output point estimates
bseed(#)	random-number seed for bootstrap
breps(#)	number of bootstrap replications; default is breps(1000)
bootcc	perform case–control (stratified on *refvar*) sampling rather than cohort sampling in bootstrap
nobstrata	ignore covariate stratification in bootstrap sampling
nodots	suppress bootstrap replication dots
* bsave(*filename*, ...)	save bootstrap replicates from parametric estimation
* bfile(*filename*)	use bootstrap replicates dataset for estimation replay

* bsave() and bfile() are allowed only when the probit option is also specified.

See [U] **20 Estimation and postestimation commands** for more capabilities of estimation commands.

Menu

Statistics > Epidemiology and related > ROC analysis > ROC regression models

Description

The rocreg command is used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data under the presence of covariates.

The two variables *refvar* and *classvar* must be numeric. The reference variable indicates the true state of the observation—such as diseased and nondiseased or normal and abnormal—and must be coded as 0 and 1. The *refvar* coded as 0 can also be called the control population, while the *refvar* coded as 1 comprises the case population. The rating or outcome of the diagnostic test or test modality is recorded in *classvar*, which must be ordinal, with higher values indicating higher risk.

rocreg can fit three models: a nonparametric model, a parametric probit model that uses the bootstrap for inference, and a parametric probit model fit using maximum likelihood.

Options for nonparametric ROC estimation, using bootstrap

Model

auc estimates the total area under the ROC curve. This is the default summary statistic.

roc(*numlist*) estimates the ROC corresponding to each of the false-positive rates in *numlist*. The values of *numlist* must be in the range (0,1).

invroc(*numlist*) estimates the false-positive rates corresponding to each of the ROC values in *numlist*. The values of *numlist* must be in the range (0,1).

pauc(*numlist*) estimates the partial area under the ROC curve up to each false-positive rate in *numlist*. The values of *numlist* must in the range (0,1].

cluster(*varname*) specifies the variable identifying resampling clusters.

ctrlcov(*varlist*) specifies the covariates to be used to adjust the control population.

`ctrlmodel(strata|linear)` specifies how to model the control population of classifiers on `ctrlcov()`. When `ctrlmodel(linear)` is specified, linear regression is used. The default is `ctrlmodel(strata)`; that is, the control population of classifiers is stratified on the control variables.

`pvc(empirical|normal)` determines how the percentile values of the control population will be calculated. When `pvc(normal)` is specified, the standard normal cumulative distribution function (CDF) is used for calculation. Specifying `pvc(empirical)` will use the empirical CDFs of the control population classifiers for calculation. The default is `pvc(empirical)`.

`tiecorrected` adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. `tiecorrected` is not allowed with `pvc(normal)`.

Reporting

`level(#)`; see [R] **estimation options**.

Also see *Options for rocreg, using bootstrap*.

Options for parametric ROC estimation, using bootstrap

Model

`probit` fits the probit model. This option is required and implies parametric estimation.

`roccov(`*varlist*`)` specifies the covariates that will affect the ROC curve.

`fprpts(#)` sets the number of false-positive rate points to use in modeling the ROC curve. These points form an equispaced grid on (0,1). The default is `fprpts(10)`.

`ctrlfprall` models the ROC curve at each false-positive rate in the control population.

`cluster(`*varname*`)` specifies the variable identifying resampling clusters.

`ctrlcov(`*varlist*`)` specifies the covariates to be used to adjust the control population.

`ctrlmodel(strata|linear)` specifies how to model the control population of classifiers on `ctrlcov()`. When `ctrlmodel(linear)` is specified, linear regression is used. The default is `ctrlmodel(strata)`; that is, the control population of classifiers is stratified on the control variables.

`pvc(empirical|normal)` determines how the percentile values of the control population will be calculated. When `pvc(normal)` is specified, the standard normal CDF is used for calculation. Specifying `pvc(empirical)` will use the empirical CDFs of the control population classifiers for calculation. The default is `pvc(empirical)`.

`tiecorrected` adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. `tiecorrected` is not allowed with `pvc(normal)`.

Reporting

`level(#)`; see [R] **estimation options**.

Also see *Options for rocreg, using bootstrap*.

Options for parametric ROC estimation, using maximum likelihood

Model

`probit` fits the probit model. This option is required and implies parametric estimation.

`ml` fits the probit model by maximum likelihood estimation. This option is required and must be specified with `probit`.

`roccov(`*varlist*`)` specifies the covariates that will affect the ROC curve.

`cluster(`*varname*`)` specifies the variable used for clustering.

`ctrlcov(`*varlist*`)` specifies the covariates to be used to adjust the control population.

Reporting

`level(#)`; see [R] **estimation options**.

display_options: `noomitted`, `cformat(%`*fmt*`)`, `pformat(%`*fmt*`)`, `sformat(%`*fmt*`)`, and `nolstretch`; see [R] **estimation options**.

Maximization

maximize_options: `difficult`, `technique(`*algorithm_spec*`)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(`*init_specs*`)`; see [R] **maximize**. These options are seldom used. The `technique(bhhh)` option is not allowed.

Options for rocreg, using bootstrap

Bootstrap

`nobootstrap` specifies that bootstrap standard errors not be calculated.

`bseed(#)` specifies the random-number seed to be used in the bootstrap.

`breps(#)` sets the number of bootstrap replications. The default is `breps(1000)`.

`bootcc` performs case–control (stratified on *refvar*) sampling rather than cohort bootstrap sampling.

`nobstrata` ignores covariate stratification in bootstrap sampling.

`nodots` suppresses bootstrap replicate dots.

`bsave(`*filename*`, ...)` saves bootstrap replicates from parametric estimation in the given *filename* with specified options (that is, `replace`). `bsave()` is only allowed with parametric analysis using bootstrap.

`bfile(`*filename*`)` specifies to use the bootstrap replicates dataset for estimation replay. `bfile()` is only allowed with parametric analysis using bootstrap.

Remarks

Remarks are presented under the following headings:

Introduction
ROC statistics
Covariate-adjusted ROC curves
Parametric ROC curves: Estimating equations
Parametric ROC curves: Maximum likelihood

Introduction

Receiver operating characteristic (ROC) analysis provides a quantitative measure of the accuracy of diagnostic tests to discriminate between two states or conditions. These conditions may be referred to as normal and abnormal, nondiseased and diseased, or control and case. We will use these terms interchangeably. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known control and case subjects.

The analysis uses the ROC curve, a graph of the sensitivity versus 1 − specificity of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus the sensitivity is the true-positive rate, and the specificity is the true-negative rate. We also call 1 − specificity the false-positive rate.

These rates are functions of the possible outcomes of the diagnostic test. At each outcome, a decision will be made by the user of the diagnostic test to classify the tested subject as either normal or abnormal. The true-positive and false-positive rates measure the probability of correct classification or incorrect classification of the subject as abnormal. Given the classification role of the diagnostic test, we will refer to it as the classifier.

Using this basic definition of the ROC curve, Pepe (2000) and Pepe (2003) describe how ROC analysis can be performed as a two-stage process. In the first stage, the control distribution of the classifier is estimated. The specificity is then determined as the percentiles of the classifier values calculated based on the control population. The false-positive rates are calculated as 1 − specificity. In the second stage, the ROC curve is estimated as the cumulative distribution of the case population's "false-positive" rates, also known as the survival function under the case population of the previously calculated percentiles. We use the terms ROC value and true-positive value interchangeably.

This formulation of ROC curve analysis provides simple, nonparametric estimates of several ROC curve summary parameters: area under the ROC curve, partial area under the ROC curve, ROC value for a given false-positive rate, and false-positive rate (also known as invROC) for a given ROC value. In the next section, we will show how to use `rocreg` to compute these estimates with bootstrap inference. There we will also show how `rocreg` complements the other nonparametric Stata ROC commands `roctab` and `roccomp`.

Other factors beyond condition status and the diagnostic test may affect both stages of ROC analysis. For example, a test center may affect the control distribution of the diagnostic test. Disease severity may affect the distribution of the standardized diagnostic test under the case population. Our analysis of the ROC curve in these situations will be more accurate if we take these covariates into account.

In a nonparametric ROC analysis, covariates may only affect the first stage of estimation; that is, they may be used to adjust the control distribution of the classifier. In a parametric ROC analysis, it is assumed that ROC follows a normal distribution, and thus covariates may enter the model at both stages; they may be used to adjust the control distribution and to model ROC as a function of these covariates and the false-positive rate. In parametric models, both sets of covariates need not be distinct but, in fact, they are often the same.

To model covariate effects on the first stage of ROC analysis, Janes and Pepe (2009) propose a covariate-adjusted ROC curve. We will demonstrate the covariate adjustment capabilities of `rocreg` in *Covariate-adjusted ROC curves*.

To account for covariate effects at the second stage, we assume a parametric model. Particularly, the ROC curve is a generalized linear model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates. In *Parametric ROC curves: Estimating equations*, we show how to fit the model with estimating equations and bootstrap inference using `rocreg`.

This method, documented as the "pdf" approach in Alonzo and Pepe (2002), works well with weak assumptions about the control distribution.

Also in *Parametric ROC curves: Estimating equations*, we show how to fit a constant-only parametric model (involving no covariates) of the ROC curve with weak assumptions about the control distribution. The constant-only model capabilities of `rocreg` in this context will be compared with those of `rocfit`. `roccomp` has the `binormal` option, which will allow it to compute area under the ROC curve according to a normal ROC curve, equivalent to that obtained by `rocfit`. We will compare this functionality with that of `rocreg`.

In *Parametric ROC curves: Maximum likelihood*, we demonstrate maximum likelihood estimation of the ROC curve model with `rocreg`. There we assume a normal linear model for the classifier on the covariates and case–control status. This method is documented in Pepe (2003). We will also demonstrate how to use this method with no covariates, and we will compare `rocreg` under the constant-only model with `rocfit` and `roccomp`.

The `rocregplot` command is used repeatedly in this entry. This command provides graphical output for `rocreg` and is documented in [R] **rocregplot**.

ROC statistics

`roctab` computes the ROC curve by calculating the false-positive rate and true-positive rate empirically at every value of the input classifier. It makes no distributional assumptions about the case or control distributions. We can get identical behavior from `rocreg` by using the default option settings.

▷ Example 1: Nonparametric ROC, AUC

Hanley and McNeil (1982) presented data from a study in which a reviewer was asked to classify, using a five-point scale, a random sample of 109 tomographic images from patients with neurological problems. The rating scale was as follows: 1 is definitely normal, 2 is probably normal, 3 is questionable, 4 is probably abnormal, and 5 is definitely abnormal. The true disease status was normal for 58 of the patients and abnormal for the remaining 51 patients.

Here we list 9 of the 109 observations:

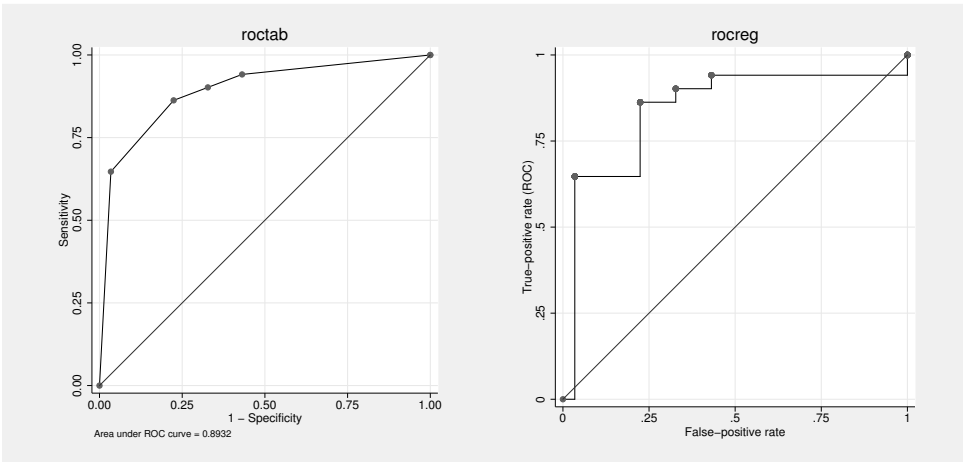
```
. use http://www.stata-press.com/data/r12/hanley
. list disease rating in 1/9
```

	disease	rating
1.	1	5
2.	0	1
3.	1	5
4.	0	4
5.	0	1
6.	0	3
7.	1	5
8.	0	5
9.	0	1

For each observation, `disease` identifies the true disease status of the subject (`0` is normal, `1` is abnormal), and `rating` contains the classification value assigned by the reviewer.

We run `roctab` on these data, specifying the `graph` option so that the ROC curve is rendered. We then calculate the false-positive and true-positive rates of the ROC curve by using `rocreg`. We graph the rates with `rocregplot`. Because we focus on `rocreg` output later, for now we use the `quietly` prefix to omit the output of `rocreg`. Both graphs are combined using `graph combine` (see [G-2] **graph combine**) for comparison. To ease the comparison, we specify the `aspectratio(1)` option in `roctab`; this is the default aspect ratio in `rocregplot`.

```
. roctab disease rating, graph aspectratio(1) name(a) nodraw title("roctab")
. quietly rocreg disease rating
. rocregplot, name(b) nodraw legend(off) title("rocreg")
. graph combine a b
```



Both `roctab` and `rocreg` compute the same false-positive rate and ROC values. The stairstep line connection style of the graph on the right emphasizes the empirical nature of its estimates. The control distribution of the classifier is estimated using the empirical CDF estimate. Similarly, the ROC curve, the distribution of the resulting case observation false-positive rate values, is estimated using the empirical CDF. Note the footnote in the `roctab` plot. By default, `roctab` will estimate the area under the ROC curve (AUC) using a trapezoidal approximation to the estimated false-positive rate and true-positive rate points.

The AUC can be interpreted as the probability that a randomly selected member of the case population will have a larger classifier value than a randomly selected member of the control population. It can also be viewed as the average ROC value, averaged uniformly over the (0,1) false-positive rate domain (Pepe 2003).

The nonparametric estimator of the AUC (DeLong, DeLong, and Clarke-Pearson 1988; Hanley and Hajian-Tilaki 1997) used by `rocreg` is equivalent to the sample mean of the percentile values of the case observations. Thus to calculate the nonparametric AUC estimate, we only need to calculate the percentile values of the case observations with respect to the control distribution.

This estimate can differ from the trapezoidal approximation estimate. Under discrete classification data, like we have here, there may be ties between classifier values from case to control. The trapezoidal approximation uses linear interpolation between the classifier values to correct for ties. Correcting the nonparametric estimator involves adding a correction term to each observation's percentile value, which measures the probability that the classifier is equal to (instead of less than) the observation's classifier value.

The tie-corrected nonparametric estimate (trapezoidal approximation) is used when we think the true ROC curve is smooth. This means that the classifier we measure is a discretized approximation of a true latent and a continuous classifier.

We now recompute the ROC curve of `rating` for classifying `disease` and calculate the AUC. Specifying the `tiecorrected` option allows tie correction to be used in the `rocreg` calculation. Under nonparametric estimation, `rocreg` bootstraps to obtain standard errors and confidence intervals for requested statistics. We use the default 1,000 bootstrap replications to obtain confidence intervals for our parameters. This is a reasonable lower bound to the number of replications (Mooney and Duval 1993) required for estimating percentile confidence intervals. By specifying the `summary` option in `roctab`, we will obtain output showing the trapezoidal approximation of the AUC estimate, along with standard error and confidence-interval estimates for the trapezoidal approximation suggested by DeLong, DeLong, and Clarke-Pearson (1988).

```

------------------------------------------------------------------------------
```

The estimates of AUC match well. The standard error from `roctab` is close to the bootstrap standard error calculated by `rocreg`. The bootstrap standard error generalizes to the more complex models that we consider later, whereas the `roctab` standard-error calculation does not.

◁

The AUC can be used to compare different classifiers. It is the most popular summary statistic for comparisons (Pepe, Longton, and Janes 2009). `roccomp` will compute the trapezoidal approximation of the AUC and graph the ROC curves of multiple classifiers. Using the DeLong, DeLong, and Clarke-Pearson (1988) covariance estimates for the AUC estimate, `roccomp` performs a Wald test of the null hypothesis that all classifier AUC values are equal. `rocreg` has similar capabilities.

Example 2: Nonparametric ROC, AUC, multiple classifiers

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 is definitely normal, 2 is probably normal, 3 is possibly normal, 4 is possibly abnormal, 5 is probably abnormal, and 6 is definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first seven observations:

```
. use http://www.stata-press.com/data/r12/ct, clear
. list in 1/7, sep(0)
```

	mod1	mod2	status
1.	2	1	0
2.	5	5	1
3.	2	1	0
4.	2	3	0
5.	5	6	1
6.	2	2	0
7.	3	2	0

Each observation corresponds to one phantom. The `mod1` variable identifies the rating assigned for the first modality, and the `mod2` variable identifies the rating assigned for the second modality. The true status of the phantoms is given by `status==0` if they are normal and `status==1` if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

A fictitious dataset was created from this true dataset, adding a third test modality. We will use `roccomp` to compute the AUC statistic for each modality in these data and compare the AUC of the three modalities. We obtain the same behavior from `rocreg`. As before, the `tiecorrected` option is specified so that the AUC is calculated with the trapezoidal approximation.

```
. use http://www.stata-press.com/data/r12/ct2
. roccomp status mod1 mod2 mod3, summary
```

```

We see that the AUC estimates are equivalent, and the standard errors are quite close as well. The p-value for the tests of equal AUC under `rocreg` leads to similar inference as the p-value from `roccomp`. The Wald test performed by `rocreg` uses the joint bootstrap estimate variance matrix of the three AUC estimators rather than the DeLong, DeLong, and Clarke-Pearson (1988) variance estimate used by `roccomp`.

`roccomp` is used here on potentially correlated classifiers that are recorded in wide-format data. It can also be used on long-format data to compare independent classifiers. Further details can be found in [R] **roccomp**.

◁

Citing the AUC's lack of clinical relevance, there is argument against using it as a key summary statistic of the ROC curve (Pepe 2003; Cook 2007). Pepe, Longton, and Janes (2009) suggest using the estimate of the ROC curve itself at a particular point, or the estimate of the false-positive rate at a given ROC value, also known as invROC.

Recall from example 1 how nonparametric rocreg graphs look, with the stairstep pattern in the ROC curve. In an ideal world, the graph would be a smooth one-to-one function, and it would be trivial to map a false-positive rate to its corresponding true-positive rate and vice versa.

However, smooth ROC curves can only be obtained by assuming a parametric model that uses linear interpolation between observed false-positive rates and between observed true-positive rates, and rocreg is certainly capable of that; see example 1 of [R] **rocregplot**. However, under nonparametric estimation, the mapping between false-positive rates and true-positive rates is not one to one, and estimates tend to be less reliable the further you are from an observed data point. This is somewhat mitigated by using tie-corrected rates (the tiecorrected option).

When we examine continuous data, the difference between the tie-corrected estimates and the standard estimates becomes negligible, and the empirical estimate of the ROC curve becomes close to the smooth ROC curve obtained by linear interpolation. So the nonparametric ROC and invROC estimates work well.

Fixing one rate value of interest can be difficult and subjective (Pepe 2003). A compromise measure is the partial area under the ROC curve (pAUC) (McClish 1989; Thompson and Zucchini 1989). This is the integral of the ROC curve from 0 and above to a given false-positive rate (perhaps the largest clinically acceptable value). Like the AUC estimate, the nonparametric estimate of the pAUC can be written as a sample average of the case observation percentiles, but with an adjustment based on the prescribed maximum false-positive rate (Dodd and Pepe 2003). A tie correction may also be applied so that it reflects the trapezoidal approximation.

We cannot compare rocreg with roctab or roccomp on the estimation of pAUC, because pAUC is not computed by the latter two.

▷ Example 3: Nonparametric ROC, other statistics

To see how rocreg estimates ROC, invROC, and pAUC, we will examine a new study. Wieand et al. (1989) examined a pancreatic cancer study with two continuous classifiers, here called y1 (CA 19-9) and y2 (CA 125). This study was also examined in Pepe, Longton, and Janes (2009). The indicator of cancer in a subject is recorded as d. The study was a case–control study, stratifying participants on disease status.

We list the first five observations:

```
. use http://labs.fhcrc.org/pepe/book/data/wiedat2b.dta, clear
(S. Wieand - Pancreatic cancer diagnostic marker data)
. list in 1/5
```

	y1	y2	d
1.	28	13.3	no
2.	15.5	11.1	no
3.	8.2	16.7	no
4.	3.4	12.6	no
5.	17.3	7.4	no

We will estimate the ROC curves at a large value (0.7) and a small value (0.2) of the false-positive rate. These values are specified in roc(). The false-positive rate for ROC or sensitivity value of 0.6 will also be estimated by specifying invroc(). Percentile confidence intervals for these parameters are displayed in the graph obtained by rocregplot after rocreg. The pAUC statistic will be calculated for the false-positive rate of 0.5, which is specified as an argument to the pauc() option. Following Pepe, Longton, and Janes (2009), we use a stratified bootstrap, sampling separately from the case

and control populations by specifying the bootcc option. This reflects the case–control nature of the study.

All four statistics can be estimated simultaneously by rocreg. For clarity, however, we will estimate each statistic with a separate call to rocreg. rocregplot is used after estimation to graph the ROC and false-positive rate estimates. The display of the individual, observation-specific false-positive rate and ROC values will be omitted in the plot. This is accomplished by specifying msymbol(i) in our plot1opts() and plot2opts() options to rocregplot.

We also find significant evidence supporting the hypothesis that the pAUC for `y1` up to a false-positive rate of 0.5 differs from the area of the same region under the ROC curve of `y2`.

◁

Covariate-adjusted ROC curves

When covariates affect the control distribution of the diagnostic test, thresholds for the test being classified as abnormal may be chosen that vary with the covariate values. These conditional thresholds will be more accurate than the marginal thresholds that would normally be used, because they take into account the specific distribution of the diagnostic test under the given covariate values as opposed to the marginal distribution over all covariate values.

By using these covariate-specific thresholds, we are essentially creating new classifiers for each covariate-value combination, and thus we are creating multiple ROC curves. As explained in Pepe (2003), when the case and control distributions of the covariates are the same, the marginal ROC curve will always be bound above by these covariate-specific ROC curves. So using conditional thresholds will never provide a less powerful test diagnostic in this case.

In the marginal ROC curve calculation, the classifiers are standardized to percentiles according to the control distribution, marginalized over the covariates. Thus the ROC curve is the CDF of the standardized case observations. The covariate-adjusted ROC curve is the CDF of one minus the conditional control percentiles for the case observations, and the marginal ROC curve is the CDF of one minus the marginal control percentiles for the case observations (Pepe and Cai 2004). Thus the standardization of classifier to false-positive rate value is conditioned on the specific covariate values under the covariate-adjusted ROC curve.

The covariate-adjusted ROC curve (Janes and Pepe 2009) at a given false-positive rate t is equivalent to the expected value of the covariate-specific ROC at t over all covariate combinations. When the covariates in question do not affect the case distribution of the classifier, the covariate-specific ROC will have the same value at each covariate combination. So here the covariate-adjusted ROC is equivalent to the covariate-specific ROC, regardless of covariate values.

When covariates do affect the case distribution of the classifier, users of the diagnostic test would likely want to model the covariate-specific ROC curves separately. Tools to do this can be found in the parametric modeling discussion in the following two sections. Regardless, the covariate-adjusted ROC curve can serve as a meaningful summary of covariate-adjusted accuracy.

Also note that the ROC summary statistics defined in the previous section have covariate-adjusted analogs. These analogs are estimated in a similar manner as under the marginal ROC curve (Janes, Longton, and Pepe 2009). The options for their calculation in `rocreg` are identical to those given in the previous section. Further details can be found in *Methods and formulas*.

▷ Example 4: Nonparametric ROC, linear covariate adjustment

Norton et al. (2000) studied data from a neonatal audiology study on three tests to identify hearing impairment in newborns. These data were also studied in Janes, Longton, and Pepe (2009). Here we list 5 of the 5,058 observations.

```
. use http://www.stata-press.com/data/r12/nnhs, clear
(Norton - neonatal audiology data)
. list in 1/5
```

	id	ear	male	currage	d	y1	y2	y3
1.	B0157	R	M	42.42	0	-3.1	-9	-1.5
2.	B0157	L	M	42.42	0	-4.5	-8.7	-2.71
3.	B0158	R	M	40.14	1	-3.2	-13.2	-2.64
4.	B0161	L	F	38.14	0	-22.1	-7.8	-2.59
5.	B0167	R	F	37	0	-10.9	-6.6	-1.42

The classifiers `y1` (DPOAE 65 at 2 kHz), `y2` (TEOAE 80 at 2 kHz), and `y3` (ABR) and the hearing impairment indicator `d` are recorded along with some relevant covariates. The infant's age is recorded in months as `currage`, and the infant's gender is indicated by `male`. Over 90% of the newborns were tested in each ear (`ear`), so we will cluster on infant ID (`id`).

Following the strategy of Janes, Longton, and Pepe (2009), we will first perform ROC analysis for the classifiers while adjusting for the covariate effects of the infant's gender and age. This is done by specifying these variables in the `ctrlcov()` option. We adjust using a linear regression rule, by specifying `ctrlmodel(linear)`. This means that when a user of the diagnostic test chooses a threshold conditional on the age and gender covariates, they assume that the diagnostic test classifier has some linear dependence on age and gender and equal variance as their levels vary. Our cluster adjustment is made by specifying the `cluster()` option.

We will focus on the first classifier. The percentile, or specificity, values are calculated empirically by default, and thus so are the false-positive rates, (1 − specificity). Also by default, the ROC curve values are empirically defined by the false-positive rates. To draw the ROC curve, we again use `rocregplot`.

The AUC is calculated by default. For brevity, we specify the `nobootstrap` option so that bootstrap sampling is not performed. The AUC point estimate will be sufficient for our purposes.

```

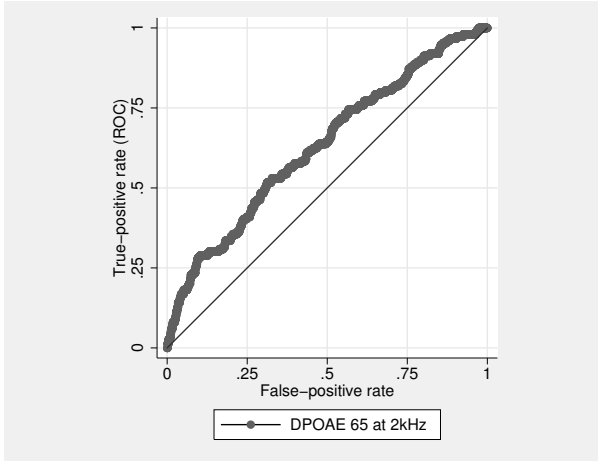
```

```
. rocregplot
```



Our covariate control adjustment model shows that `currage` has a negative effect on `y1` (DPOAE 65 at 2 kHz) under the control population. At the 0.001 significance level, we reject that its contribution to `y1` is zero, and the point estimate has a negative sign. This result does not directly tell us about the effect of `currage` on the ROC curve of `y1` as a classifier of `d`. None of the case observations are used in the linear regression, so information on `currage` for abnormal cases is not used in the model. This result does show us how to calculate false-positive rates for tests that use thresholds conditional on a child's sex and current age. We will see how `currage` affects the ROC curve when `y1` is used as a classifier and conditional thresholds are used based on `male` and `currage` in the following section, *Parametric ROC curves: Estimating equations*.

❑ Technical note

Under this nonparametric estimation, `rocreg` saved the false-positive rate for each observation's `y1` values in the utility variable `_fpr_y1`. The true-positive rates are stored in the utility variable `_roc_y1`. For other models, say with classifier *yname*, these variables would be named `_fpr_`*yname* and `_roc_`*yname*. They will also be overwritten with each call of `rocreg`. The variables `_roc_*` and `_fpr_*` are usually for internal `rocreg` use only and are overwritten with each call of `rocreg`. They are only created for nonparametric models or parametric models that do not involve ROC covariates. In these models, covariates may only affect the first stage of estimation, the control distribution, and not the ROC curve itself. In parametric models that allow ROC covariates, different covariate values would lead to different ROC curves.

❑

To see how the covariate-adjusted ROC curve estimate differs from the standard marginal estimate, we will reestimate the ROC curve for classifier `y1` without covariate adjustment. We rename these variables before the new estimation and then draw an overlaid `twoway line` (see [G-2] **graph twoway line**) plot to compare the two.

```
. rename _fpr_y1 o_fpr_y1
. rename _roc_y1 o_roc_y1
. label variable o_roc_y1 "covariate_adjusted"
. rocreg d y1, cluster(id) nobootstrap

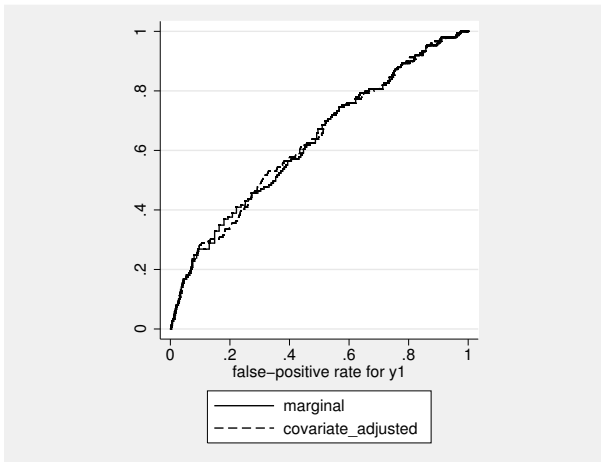
     line o_roc_y1 o_fpr_y1, sort(o_fpr_y1 o_roc_y1)
     connect(J) lpattern(dash) aspectratio(1) legend(cols(1))
```



Though they are close, particularly in AUC, there are clearly some points of difference between the estimates. So the covariate-adjusted ROC curve may be useful here.

◁

In our examples thus far, we have used the empirical CDF estimator to estimate the control distribution. `rocreg` allows some flexibility here. The `pvc(normal)` option may be specified to calculate the percentile values according to a Gaussian distribution of the control.

Covariate adjustment in `rocreg` may also be performed with stratification instead of linear regression. Under the stratification method, the unique values of the stratified covariates each define separate parameters for the control distribution of the classifier. A user of the diagnostic test chooses a threshold based on the control distribution conditioned on the unique covariate value parameters.

We will demonstrate the use of normal percentile values and covariate stratification in our next example.

▷ Example 5: Nonparametric ROC, covariate stratification

The hearing test study of Stover et al. (1996) examined the effectiveness of negative signal-to-noise ratio, `nsnr`, as a classifier of hearing loss. The test was administered under nine different settings, corresponding to different frequency, `xf`, and intensity, `xl`, combinations. Here we list 10 of the 1,848 observations.

```
. use http://www.stata-press.com/data/r12/dp, clear
(Stover - DPOAE test data)
. list in 1/10
```

	id	d	nsnr	xf	xl	xd
1.	101	1	18	10.01	5.5	3.5
2.	101	1	19	20.02	5.5	3
3.	101	1	7.6	10.01	6	3.5
4.	101	1	15	20.02	6	3
5.	101	1	16	10.01	6.5	3.5
6.	101	1	5.8	20.02	6.5	3
7.	102	0	-2.6	10.01	5.5	.
8.	102	0	-3	14.16	5.5	.
9.	102	1	10	20.02	5.5	1
10.	102	0	-5.8	10.01	6	.

Hearing loss is represented by `d`. The covariate `xd` is a measure of the degree of hearing loss. We will use this covariate in later analysis, because it only affects the case distribution of the classifier. Multiple measurements are taken for each individual, `id`, so we will cluster by individual.

We evaluate the effectiveness of `nsnr` using `xf` and `xl` as stratification covariates with `rocreg`; the default method of covariate adjustment.

As mentioned before, the default false-positive rate calculation method in `rocreg` estimates the conditional control distribution of the classifiers empirically. For comparison, we will also estimate a separate ROC curve using false-positive rates assuming the conditional control distribution is normal. This behavior is requested by specifying the `pvc(normal)` option. Using the `rocregplot` option `name()` to store the ROC plots and using the `graph combine` command, we are able to compare the Gaussian and empirical ROC curves side by side. As before, for brevity we specify the `nobootstrap` option to suppress bootstrap sampling.

```

Area under the ROC curve
   Status    : d
   Classifier: nsnr
```

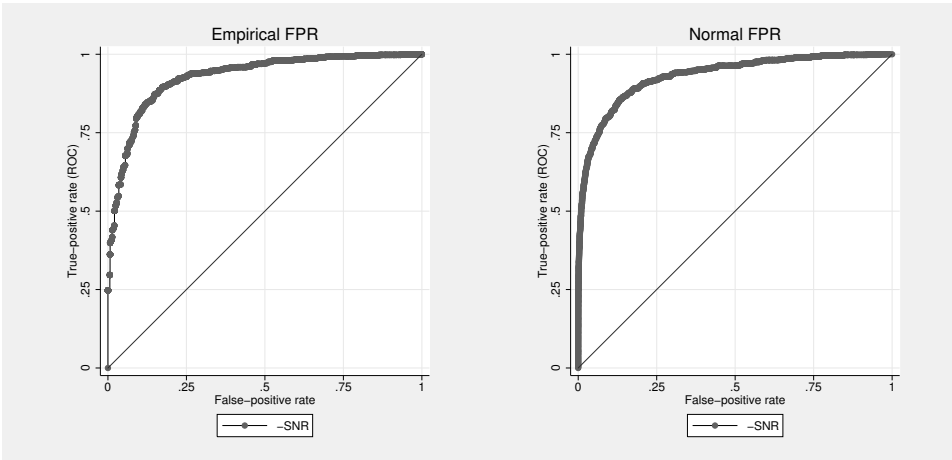
AUC	Observed Coef.	Bias	Bootstrap Std. Err.	[95% Conf. Interval]	
	.9309901	.	.	.	. (N)
				.	. (P)
				.	. (BC)

```
. rocregplot, title(Normal FPR) name(b) nodraw
. graph combine a b, xsize(5)
```



On cursory visual inspection, we see little difference between the two curves. The AUC values are close as well. So it is sensible to assume that we have Gaussian percentile values for control standardization. ◁

Parametric ROC curves: Estimating equations

We now assume a parametric model for covariate effects on the second stage of ROC analysis. Particularly, the ROC curve is a probit model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations as described in Alonzo and Pepe (2002). This method can be also be used without covariate effects in the second stage, assuming a parametric model for the single (constant only) ROC curve. Covariates may still affect the first stage of estimation, so we parametrically model the single covariate-adjusted ROC curve (from the previous section). The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well.

In addition to the Alonzo and Pepe (2002) explanation, further details are given in Pepe, Longton, and Janes (2009); Janes, Longton, and Pepe (2009); Pepe (2003); and Janes and Pepe (2009).

The parametric models that we consider assume that the ROC curve is a cumulative distribution function g invoked with input of a linear polynomial in the corresponding quantile function invoked on the false-positive rate u. In this context, we assume that g corresponds to a standard normal cumulative distribution function, Φ. So the corresponding quantile function is Φ^{-1}. The constant intercept of the polynomial may depend on covariates, but the slope term α (the quantile coefficient) may not.

$$\text{ROC}(u) = g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(u)\}$$

The first step of the algorithm involves the choice of false-positive rates to use in the parametric fit. These are typically a set of equispaced points spanning the interval (0,1). Alonzo and Pepe (2002) examined the effect of fitting large and small sets of points, finding that relatively small sets could be used with little loss of efficiency. Alternatively, the set can be formed by using the observed false-positive rates in the data (Pepe 2003). Further details on the algorithm are provided in *Methods and formulas*.

Under parametric estimation, all the summary measures we defined earlier, except the AUC, are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are initially estimated. In marginal parametric models (where there are no ROC covariates, but there are potentially control covariates), we will calculate the AUC and leave the other measures for postestimation; see [R] **rocreg postestimation**. As with the other parameters, we bootstrap for standard errors and inference.

We will now demonstrate how `rocreg` performs the Alonzo and Pepe (2002) algorithm using the previous section's examples and others.

▷ Example 6: Parametric ROC, linear covariate adjustment

We return to the neonatal audiology study with gender and age covariates (Norton et al. 2000), which we discussed in example 4. Janes, Longton, and Pepe (2009) suspected the current age of the infant would play a role in the case distribution of the classifier `y1` (DPOAE 65 at 2 kHz). They postulated a probit link between the ROC curve and the covariate-adjusted false-positive rates. We follow their investigation and reach similar results.

In example 4, we saw the results of adjusting for the `currage` and `male` variables in the control population for classifier `y1`. Now we see how `currage` affects the ROC curve when `y1` is used with thresholds conditioned on `male` and `currage`.

We specify the covariates that should affect the ROC curve in the `roccov()` option. By default, `rocreg` will choose 10 equally spaced false-positive rates in the (0,1) interval as fitting points. The `fprpts()` option allows the user to specify more or fewer points. We specify the `bsave()` option with the `nnhs2y1` dataset so that we can use the bootstrap resamples in postestimation.

```
. use http://www.stata-press.com/data/r12/nnhs, clear
(Norton - neonatal audiology data)
. rocreg d y1, probit ctrlcov(currage male) ctrlmodel(linear) roccov(currage)
> cluster(id) bseed(56930) bsave(nnhs2y1) nodots
Bootstrap results                                 Number of obs      =      5056
                                                  Replications       =      1000

```

Note how the number of clusters—here infants—changes from the covariate control adjustment model fit to the ROC model. The control fit is limited to control cases and thus fewer infants. The ROC is fit on all the data, so the variance is adjusted for all clustering on all infants.

With a 0.05 level of statistical significance, we cannot reject the null hypothesis that `currage` has no effect on the ROC curve at a given false-positive rate. This is because each of our 95% bootstrap confidence intervals contains 0. This corresponds with the finding in Janes, Longton, and Pepe (2009) where the reported 95% intervals each contained 0. We cannot reject that the intercept parameter β_0, reported as `_cons` in the main table, is 0 at the 0.05 level either. The slope parameter α, reported

as _cons in the probit table, is close to 1 and cannot be rejected as being 1 at the 0.05 level. Under the assumption that the ROC coefficients except α are 0 and that $\alpha = 1$, the ROC curve at false-positive rate u is equal to u. In other words, we cannot reject that the false-positive rate is equal to the true-positive rate, and so the test is noninformative. Further investigation of the results requires postestimation; see [R] **rocreg postestimation**.

◁

The fitting point set can be formed by using the observed false-positive rates (Pepe 2003). Our next example will illustrate this.

▷ Example 7: Parametric ROC, covariate stratification

We return to the hearing test study of Stover et al. (1996), which we discussed in example 5. Pepe (2003) suspected that intensity, xd, would play a role in the case distribution of the negative signal-to-noise ratio (nsnr) classifier. A ROC regression was fit with covariate adjustment for xf and xl with stratification, and for ROC covariates xf, xl, and xd. There is no prohibition against the same covariate being used in the first and second stages of ROC calculation. The false-positive rate fitting point set was composed of all observed false-positive rates in the control data.

We fit the model with rocreg here. Using observed false-positive rates as the fitting point set can make the dataset very large, so fitting the model is computationally intensive. We demonstrate the fitting algorithm without precise confidence intervals, focusing instead on the coefficient estimates and standard errors. We will thus perform only 50 bootstrap replications, a reasonable number to obtain accurate standard error estimates (Mooney and Duval 1993). The number of replications is specified in the breps() option.

The ROC covariates are specified in roccov(). We specify that all observed false-positive rates in the control observations be used as fitting points with the ctrlfprall option. The nobstrata option specifies that the bootstrap is not stratified. The covariate stratification in the first stage of estimation does not affect the resampling. We will return to this example in postestimation, so we save the bootstrap results in the nsnrf dataset with the bsave() option.

```
. use http://www.stata-press.com/data/r12/dp
(Stover - DPOAE test data)

. rocreg d nsnr, probit ctrlcov(xf xl) roccov(xf xl xd) ctrlfprall cluster(id)
> nobstrata bseed(156385) breps(50) bsave(nsnrf)
(running rocregstat on estimation sample)

Bootstrap replications (50)
----+--- 1 ---+--- 2 ---+--- 3 ---+--- 4 ---+--- 5
..................................................    50

Bootstrap results                                 Number of obs      =      1848
                                                  Replications       =        50

Parametric ROC estimation

probit						
_cons	1.032657	-.0188887	.1224993	.7925628	1.272751	(N)
				.7815666	1.236179	(P)
				.7815666	1.237131	(BC)

We obtain results similar to those reported in Pepe (2003, 159). Unlike in our previous example, we find that the coefficients for `xl` and `xd` differ from 0 at the 0.05 level of significance. So over certain covariate combinations, we can have a variety of informative tests using `nsnr` as a classifier. ◁

As mentioned before, when there are no covariates, `rocreg` can still fit a parametric model for the ROC curve of a classifier by using the Alonzo and Pepe (2002) method. `roccomp` and `rocfit` can fit marginal probit models as well. We will compare the behavior of `rocreg` with that of `roccomp` and `rocfit` for probit models without covariates.

When the `binormal` option is specified, `roccomp` calculates the AUC for input classifiers according to the maximum likelihood algorithm of `rocfit`. The `rocfit` algorithm expects discrete classifiers but can slice continuous classifiers into discrete partitions. Further, the case and control distributions are both assumed normal. Actually, the observed classification values are taken as discrete indicators

of the latent normally distributed classification values. This method is documented in Dorfman and Alf (1969).

Alonzo and Pepe (2002) compared their estimating equations probability density function method (with empirical estimation of the false-positive rates) to the maximum likelihood approach of Dorfman and Alf (1969) and found that they had similar efficiency and mean squared error. So we should expect `rocfit` and `rocreg` to give similar results when fitting a simple probit model.

▷ Example 8: Parametric ROC, marginal model

We return to the Hanley and McNeil (1982) data. We will fit a probit model to the ROC curve, assuming that the `rating` variable is a discrete indicator of an underlying latent normal random variable in both the case and control populations of `disease`. We invoke `rocfit` with the default options. `rocreg` is invoked with the `probit` option. The percentile values are calculated empirically. Because there are fewer categories than 10, there will be fewer than 10 false-positive rates that trigger a different true-positive rate value. So for efficiency, we invoke `rocreg` with the `ctrlfprall` option.

```
. use http://www.stata-press.com/data/r12/hanley

_cons	.6951252	.0572146	.3241451	.0598125	1.330438	(N)
				.3500569	1.430441	(P)
				.3372983	1.411953	(BC)

AUC	Observed Coef.	Bias	Bootstrap Std. Err.	[95% Conf.	Interval]	
	.9102903	-.0051749	.0314546	.8486405	.9719402	(N)
				.837113	.9605498	(P)
				.8468336	.9630486	(BC)

We see that the intercept and slope parameter estimates are close. The intercept (`_cons` in the main table) is clearly nonzero. Under `rocreg`, the slope (`_cons` in the `probit` table) and its percentile and bias-corrected confidence intervals are close to those of `rocfit`. The area under the ROC curve for each of the `rocreg` and `rocfit` estimators also matches closely.

◁

Now we will compare the parametric fit of `rocreg` under the constant probit model with `roccomp`.

▷ Example 9: Parametric ROC, marginal model, multiple classifiers

We now use the fictitious dataset generated from Hanley and McNeil (1983). To fit a probit model using `roccomp`, we specify the `binormal` option. Our specification of `rocreg` remains the same as before.

`rocregplot` is used to render the model produced by `rocreg`. We specify several graph options to both `roccomp` and `rocregplot` to ease comparison. When the `binormal` option is specified along with `graph`, `roccomp` will draw the binormal fitted lines in addition to connected line plots of the empirical false-positive and true-positive rates.

In this plot, we overlay scatterplots of the empirical false-positive rates (because percentile value calculation defaulted to `pvc(empirical)`) and the parametric true-positive rates.

We see differing true-positive rate values in the scattered points, which is expected because `roccomp` gives the empirical estimate and `rocreg` gives the parametric estimate. However, the estimated curves and areas under the ROC curve look similar. Using the Wald test based on the bootstrap covariance, `rocreg` rejects the null hypothesis that each test has the same AUC at the 0.1 significance level. `roccomp` formulates the asymptotic covariance using the `rocfit` estimates of AUC. Examination of its output leads to rejection of the null hypothesis that the AUCs are equal across each test at the 0.05 significance level.

◁

Parametric ROC curves: Maximum likelihood

The Alonzo and Pepe (2002) method of fitting a parametric model to the ROC curve is powerful because it can be generally applied, but that can be a limitation as well. Whenever we invoke the method and want anything other than point estimates of the parameters, we must perform bootstrap resampling.

An alternative is to use maximum likelihood inference to fit the ROC curve. This method can save computational time by avoiding the bootstrap.

`rocreg` implements maximum likelihood estimation for ROC curve analysis when both the case and control populations are normal. Particularly, the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. This model is defined in Pepe (2003, 145).

$$y = \mathbf{z}'\boldsymbol{\beta_0} + D\mathbf{x}'\boldsymbol{\beta_1} + \sigma\left(D\right)\epsilon$$

Our error term, ϵ, is a standard normal random variable. The variable D is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function σ is defined as

$$\sigma\left(D\right) = \sigma_0\left(D=0\right) + \sigma_1\left(D=1\right)$$

This provides two variance parameters in the model and does not depend on covariate values.

Suppose a covariate x_i is present in $\mathbf{z}$ and $\mathbf{x}$. The coefficient β_{1i} represents the interaction effect of the x_i and D. It is the extra effect that x_i has on classifier y under the case population, $D = 1$, beyond the main effect β_{0i}. These $\boldsymbol{\beta_1}$ coefficients are directly related to the ROC curve of y.

Under this model, the ROC curve is derived to be

$$\text{ROC}(u) = \Phi\left[\frac{1}{\sigma_1}\{\mathbf{x}'\boldsymbol{\beta_1} + \sigma_0\Phi^{-1}(u)\}\right]$$

For convenience, we reparameterize the model at this point, creating the parameters $\beta_i = \sigma_1^{-1}\beta_{1i}$ and $\alpha = \sigma_1^{-1}\sigma_0$. We refer to β_0 as the constant intercept, `i_cons`. The parameter α is referred to as the constant slope, `s_cons`.

$$\text{ROC}(u) = \Phi\{\mathbf{x}'\boldsymbol{\beta} + \alpha\Phi^{-1}(u)\}$$

We may interpret the final coefficients as the standardized linear effect of the ROC covariate on the classifier under the case population. The marginal effect of the covariate on the classifier in the control population is removed, and it is rescaled by the case population standard deviation of the classifier when all ROC covariate effects are removed. An appreciable effect on the classifier by a ROC covariate in this measure leads to an appreciable effect on the classifier's ROC curve by the ROC covariate.

The advantage of estimating the control coefficients $\boldsymbol{\beta_0}$ is similar to the gains of estimating the covariate control models in the estimating equations ROC method and nonparametric ROC estimation. This model would similarly apply when evaluating a test that is conditioned on control covariates.

Again we note that under parametric estimation, all the summary measures we defined earlier except the AUC are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are estimated initially. In marginal parametric models, we will calculate the AUC and leave the other measures for postestimation. There is a simple closed-form formula for the AUC under the probit model. Using this formula, the delta method can be invoked for inference on the AUC. Details on AUC estimation for probit marginal models are found in *Methods and formulas*.

We will demonstrate the maximum likelihood method of `rocreg` by revisiting the models of the previous section.

▷ Example 10: Maximum likelihood ROC, single classifier

Returning to the hearing test study of Stover et al. (1996), we use a similar covariate grouping as before. The frequency `xf` and intensity `xl` are control covariates (`z`), while all three covariates `xf`, `xl`, and hearing loss degree `xd` are case covariates (`x`). In example 7, we fit this model using the Alonzo and Pepe (2002) method. Earlier we stratified on the control covariates and estimated the conditioned control distribution of `nsnr` empirically. Now we assume a normal linear model for `nsnr` on `xf` and `xl` under the control population.

We fit the model by specifying the control covariates in the `ctrlcov()` option and the case covariates in the `roccov()` option. The `ml` option tells `rocreg` to perform maximum likelihood estimation.

s_cons	.9688578	.0623476	15.54	0.000	.8466587	1.091057

We find the results are similar to those of example 7. Frequency (`xf`) and intensity (`xl`) have a negative effect on the classifier `nsnr` in the control population.

The negative control effect is mitigated for `xf` in the case population, but the effect for `xl` is even more negative there. Hearing loss severity, `xd`, has a positive effect on `nsnr` in the case population, and it is undefined in the control population.

The ROC coefficients are shown in the `ROC Model` table. Each are different from 0 at the 0.05 level. At this level, we also cannot conclude that the variances differ from case to control populations, because 1 is in the 95% confidence interval for `s_cons`, the ratio of the case to control standard deviation parameters.

Both frequency (xf) and hearing loss severity (xd) make a positive contribution to the ROC curve and thus make the test more powerful. Intensity (xl) has a negative effect on the ROC curve and weakens the test. We previously saw in example 5 that the control distribution appears to be normal, so using maximum likelihood to fit this model is a reasonable approach.

This model was also fit in Pepe (2003, 147). Pepe used separate least-squares estimates for the case and control samples. We obtain similar results for the coefficients, but the maximum likelihood fitting yields slightly different standard deviations by considering both case and control observations concurrently. In addition, a misprint in Pepe (2003, 147) reports a coefficient of −4.91 for xl in the case population instead of −3.19 as reported by Stata.

◁

Inference on multiple classifiers using the Alonzo and Pepe (2002) estimating equation method is performed by fitting each model separately and bootstrapping to determine the dependence of the estimates. Using the maximum likelihood method, we also fit each model separately. We use suest (see [R] **suest**) to estimate the joint variance–covariance of our parameter estimates.

For our models, we can view the score equation for each model as an estimating equation. The estimate that solves the estimating equation (that makes the score 0) is asymptotically normal with a variance matrix that can be estimated using the inverse of the squared scores. By stacking the score equations of the separate models, we can estimate the variance matrix for all the parameter estimates by using this rule. This is an informal explanation; further details can be found in [R] **suest** and in the references Rogers (1993); White (1982 and 1996).

Now we will examine a case with multiple classification variables.

▷ Example 11: Maximum likelihood ROC, multiple classifiers

We return to the neonatal audiology study with gender and age covariates (Norton et al. 2000). In example 6, we fit a model with male and currage as control covariates, and currage as a ROC covariate for the classifier y1 (DPOAE 65 at 2 kHz). We will refit this model, extending it to include the classifier y2 (TEOAE 80 at 2 kHz).

```

Both classifiers have similar results. The results for `y1` show the same direction as the estimating equation results in example 6. However, we can now reject the null hypothesis that the ROC `currage` coefficient is 0 at the 0.05 level.

In example 6, we could not reject that the slope parameter `s_cons` was 1 and that the constant intercept or ROC coefficient for current age was 0. The resulting ROC curve implied a noninformative test using `y1` as a classifier. This is not the case with our current results. As `currage` increases, we expect a steeper ROC curve and thus a more powerful test, for both classifiers `y1` (DPOAE 65 at 2 kHz) and `y2` (TEOAE 80 at 2 kHz).

In example 10, the clustering of observations within infant `id` was adjusted in the individual fit of `nsnr`. In our current example, the adjustment for the clustering of observations within `id` is performed during concurrent estimation, as opposed to during the individual classifier fits (as in example 10). This adjustment, performed by `suest`, is still accurate.

◁

Now we will fit constant probit models and compare `rocreg` with `rocfit` and `roccomp` with the `binormal` option. Our first applications of `rocfit` and `roccomp` are taken directly from examples 8 and 9. The Dorfman and Alf (1969) algorithm that `rocfit` works with uses discrete classifiers or uses slicing to make a classifier discrete. So we are applying the maximum likelihood method of `rocreg` on discrete classification data here, where it expects continuous data. We expect to see some discrepancies, but we do not find great divergence in the estimates. After revisiting examples 8 and 9, we will fit a probit model with a continuous classifier and no covariates using `rocreg`, and we will compare the results with those from `rocfit`.

▷ Example 12: Maximum likelihood ROC, marginal model

Using the Hanley and McNeil (1982) data, discussed in example 1 and in example 8, we fit a constant probit model of the classifier `rating` with true status `disease`. `rocreg` is invoked with the `ml` option and compared with `rocfit`.

```
. use http://www.stata-press.com/data/r12/hanley, clear

rating						
i_cons	2.090802	.2941411	7.11	0.000	1.514297	2.667308
s_cons	1.181151	.1603263	7.37	0.000	.8669177	1.495385
auc	.9116494	.0261658	34.84	0.000	.8603654	.9629333

We compare the estimates for these models:

	rocfit	rocreg, ml
slope	0.7130	1.1812
SE of slope	0.2159	0.1603
intercept	1.6568	2.0908
SE of intercept	0.3105	0.2941
AUC	0.9113	0.9116
SE of AUC	0.0295	0.0262

We find that both the intercept and the slope are estimated as higher with the maximum likelihood method under rocreg than with rocfit. The AUC (ROC area in rocfit) is close for both commands. We find that the standard errors of each of these estimates is slightly lower under rocreg than rocfit as well.

Both rocfit and rocreg suggest that the slope parameter of the ROC curve (slope in rocfit and s_cons in rocreg) is not significantly different from 1. Thus we cannot reject that the classifier has the same variance in both case and control populations. There is, however, significant evidence that the intercepts (i_cons in rocreg and intercept in rocfit) differ from 0. Because of the positive direction of the intercept estimates, the ROC curve for rating as a classifier of disease suggests that rating provides an informative test. This is also suggested by the high AUC, which is significantly different from 0.5, that is, a flip of a coin.

◁

▷ Example 13: Maximum likelihood ROC, marginal model, multiple classifiers

We use the fictitious dataset generated from Hanley and McNeil (1983), which we previously used in example 2 and in example 9. To fit a probit model using roccomp, we specify the binormal option. We perform parametric, maximum likelihood ROC analysis using rocreg. We use rocregplot to plot the ROC curves created by rocreg.

We compare the AUC estimates for these models:

	roccomp	rocreg, ml
mod1	0.8945	0.9047
mod2	0.9382	0.9580
mod3	0.9376	0.9453

Each classifier has a higher estimated AUC under rocreg than roccomp. Each curve appears to be raised and smoothed in the rocreg fit as compared with roccomp. They are different, but not drastically different. The inference on whether the curve areas are the same is similar to example 9. We reject equality at the 0.10 level under rocreg and at the 0.05 level under roccomp.

Each intercept is significantly different from 0 at the 0.05 level and is estimated in a positive direction. Though all but classifier mod2 has 1 in their slope confidence intervals, the high intercepts suggest steep ROC curves and powerful tests.

Also note that the false-positive and true-positive rate points are calculated empirically in the roccomp graph and parametrically in rocreg. In example 9, the false-positive rates calculated by rocreg were calculated empirically, similar to roccomp. But in this example, the rates are calculated based on normal percentiles.

◁

Now we will generate an example to compare rocfit and rocreg under maximum likelihood estimation of a continuous classifier.

▷ Example 14: Maximum likelihood ROC, graphical comparison with rocfit

We generate 500 realizations of a population under threat of disease. One quarter of the population has the disease. A classifier x is measured, which has a control distribution of $N(1,3)$ and a case distribution of $N(1+5,2)$. We will invoke rocreg with the ml option on this generated data. We specify the continuous() option for rocfit and invoke it on the data as well. The continuous() option tells rocfit how many discrete slices to partition the data into before fitting.

For comparison of the two curves, we will use the rocfit postestimation command, rocplot; see [R] **rocfit postestimation**. This command graphs the empirical false-positive and true-positive rates with an overlaid fit of the binormal curve estimated by rocfit. rocplot also supports an addplot() option. We use the saved variables from rocreg in this option to overlay a line plot of the rocreg fit.

```

We find that the curves are close. As before, the `rocfit` estimates are lower for the slope and intercept than under `rocreg`. The AUC estimates are close. Though the slope confidence interval contains 1, a high ROC intercept suggests a steep ROC curve and thus a powerful test.

e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample

Methods and formulas

rocreg is implemented as an ado-file.

Assume that we applied a diagnostic test to each of N_0 control and N_1 case subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let $y_{1i}, i = 1, 2, \ldots, N_1$, and $y_{0j}, j = 1, 2, \ldots, N_0$, be the values of the diagnostic test for the case and control subjects, respectively. The true status variable D identifies an observation as case $D = 1$ or control $D = 0$. The CDF of the classifier Y is F. Conditional on D, we write the CDF as F_D.

Methods and formulas are presented under the following headings:

ROC statistics
Covariate-adjusted ROC curves
Parametric ROC curves: Estimating equations
Parametric ROC curves: Maximum likelihood

ROC statistics

We obtain these definitions and their estimates from Pepe (2003) and Pepe, Longton, and Janes (2009). The false-positive and true-positive rates at cutoff c are defined as

$$\text{FPR}(y) = P\left(Y \geq y \middle| D = 0\right)$$

$$\text{TPR}(y) = P\left(Y \geq y \middle| D = 1\right)$$

The true-positive rate, or ROC value at false-positive rate u, is given by

$$\text{ROC}(u) = P\left(1 - F_0(Y) \leq u \middle| D = 1\right)$$

When Y is continuous, the false-positive rate can be written as

$$\text{FPR}(y) = 1 - F_0(y)$$

The empirical CDF for the sample $z_1, \ldots, z_n$ is given by

$$\widehat{F}(z) = \sum_{i=1}^{n} \frac{I(z < z_i)}{n}$$

The empirical estimates $\widehat{\text{FPR}}$ and $\widehat{\text{ROC}}$ both use this empirical CDF estimator.

The area under the ROC curve is defined as

$$\text{AUC} = \int_0^1 \text{ROC}(u)\, d_u$$

The partial area under the ROC curve for false-positive rate a is defined as

$$\text{pAUC}(a) = \int_0^a \text{ROC}(u)\, d_u$$

The nonparametric estimate for the AUC is given by

$$\widehat{\text{AUC}} = \sum_{i=1}^{N_1} \frac{1 - \widehat{\text{FPR}}(y_{1i})}{N_1}$$

The nonparametric estimate of pAUC is given by

$$\widehat{\text{pAUC}}(a) = \sum_{i=1}^{N_1} \frac{\max\left\{1 - \widehat{\text{FPR}}(y_{1i}) - (1-a), 0\right\}}{N_1}$$

For discrete classifiers, a correction term is subtracted from the false-positive rate estimate so that the $\widehat{\text{AUC}}$ and $\widehat{\text{pAUC}}$ estimates correspond with a trapezoidal approximation to the area of the ROC curve.

$$\text{FPR}^c(y) = 1 - \widehat{F}_0(y) - \frac{1}{2}\sum_{j=1}^{N_0} \frac{I(y = y_{0j})}{N_0}$$

In the nonparametric estimation of the ROC curve, all inference is performed using the `bootstrap` command (see [R] **bootstrap**). `rocreg` also allows users to calculate the ROC curve and related statistics by assuming a normal control distribution. So these formulas are updated by replacing F_0 by Φ (with adjustment of the marginal mean and variance of the control distribution).

Covariate-adjusted ROC curves

Suppose we observe covariate vector Z in addition to the classifier Y. Let $Z_{1i}, i = 1, 2, \ldots, N_1$, and $Z_{0j}, j = 1, 2, \ldots, N_0$, be the values of the covariates for the case and control subjects, respectively.

The covariate-adjusted ROC curve is defined by Janes and Pepe (2009) as

$$\text{AROC}(t) = E\left\{\text{ROC}\left(t\middle|Z_0\right)\right\}$$

It is calculated by replacing the marginal control CDF estimate, $\widehat{F}_0$, with the conditional control CDF estimate, $\widehat{F}_{0Z}$. If we used a normal control CDF, then we would replace the marginal control mean and variance with the conditional control mean and variance. The formulas of the previous section can be updated for covariate-adjustment by making this substitution of the conditional CDF for the marginal CDF in the false-positive rate calculation.

Because the calculation of the ROC value is now performed based on the conditionally calculated false-positive rate, no further conditioning is made in its calculation under nonparametric estimation.

`rocreg` supports covariate adjustment with stratification and linear regression. Under stratification, separate parameters are estimated for the control distribution at each level of the covariates. Under linear regression, the classifier is regressed on the covariates over the control distribution, and the resulting coefficients serve as parameters for $\widehat{F}_{0Z}$.

Parametric ROC curves: Estimating equations

Under nonparametric estimation of the ROC curve with covariate adjustment, no further conditioning occurs in the ROC curve calculation beyond the use of covariate-adjusted false-positive rates as inputs.

Under parametric estimation of the ROC curve, we can relax this restriction. We model the ROC curve as a cumulative distribution function g (standard normal Φ) invoked with input of a linear polynomial in the corresponding quantile function (here Φ^{-1}) invoked on the false-positive rate u. The constant intercept of the polynomial may depend on covariates; the slope term α (quantile coefficient) may not.

$$\text{ROC}(u) = g\{\mathbf{x}'\boldsymbol{\beta} + \alpha g^{-1}(u)\}$$

Pepe (2003) notes that having a binormal ROC ($g = \Phi$) is equivalent to specifying that some monotone transformation of the data exists to make the case and control classifiers normally distributed. This specification applies to the marginal case and control.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations (Alonzo and Pepe 2002). The method can be used without covariate effects in the second stage, assuming a parametric model for the single ROC curve. Using the Alonzo and Pepe (2002) method, the covariate-adjusted ROC curve may be fit parametrically. The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well. In addition to the Alonzo and Pepe (2002) explanation, further details are given in Pepe, Longton, and Janes (2009); Janes, Longton, and Pepe (2009); Pepe (2003); and Janes and Pepe (2009).

The algorithm can be described as follows:

1. Estimate the false-positive rates of the classifier `fpr`. These may be computed in any fashion outlined so far: covariate-adjusted, empirically, etc.
2. Determine a set of n_p false-positive rates to use as fitting points $f_1, \ldots, f_{n_p}$. These may be an equispaced grid on $(0, 1)$ or the set of observed false-positive rates from part 1.

3. Expand the case observation portion of the data to include a subobservation for each fitting point. So there are now $N_1(n_p - 1)$ additional observations in the data.
4. Generate a new dummy variable `u`. For subobservation j, $\texttt{u} = I\,(\texttt{fpr} \leq f_j)$.
5. Generate a new variable `quant` containing the quantiles of the false-positive rate fitting points. For subobservation j, $\texttt{quant} = g^{-1}\,(f_j)$.
6. Perform a binary regression (probit, $g = \Phi$) of `fpr` on the covariates `x` and quantile variable `quant`.

The coefficients of part 6 are the coefficients of the ROC model. The coefficients of the covariates coincide naturally with estimates of $\boldsymbol{\beta}$, and the α parameter is estimated by the coefficient on `quant`. Because the method is so general and makes few distributional assumptions, bootstrapping must be performed for inference. If multiple classifiers are to be fit, the algorithm is performed separately for each in each bootstrap, and the bootstrap is used to estimate covariances.

We mentioned earlier that in parametric estimation, the AUC was the only summary parameter that could be estimated initially. This is true when we fit the marginal probit model because there are no covariates in part 6 of the algorithm.

To calculate the AUC statistic under a marginal probit model, we use the formula

$$\text{AUC} = \Phi\left(\frac{\beta_0}{\sqrt{1+\alpha^2}}\right)$$

Alternatively, the AUC for the probit model can be calculated as pAUC(1) in postestimation. Under both models, bootstrapping is performed for inference on the AUC.

Parametric ROC curves: Maximum likelihood

`rocreg` supports another form of parametric ROC estimation: maximum likelihood with a normally distributed classifier. This method assumes that the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. The model is defined in Pepe (2003, 145).

$$y = \mathbf{z}'\boldsymbol{\beta_0} + D\mathbf{x}'\boldsymbol{\beta_1} + \sigma\,(D)\,\epsilon$$

Our error term, ϵ, is a standard normal random variable. The variable D is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function σ is defined as

$$\sigma\,(D) = \sigma_0\,(D = 0) + \sigma_1\,(D = 1)$$

This provides two variance parameters in the model and does not depend on covariate values.

Under this model, the ROC curve is easily derived to be

$$\text{ROC}\,(u) = \Phi\left[\frac{1}{\sigma_1}\left\{\mathbf{x}'\boldsymbol{\beta_1} + \sigma_0\Phi^{-1}\,(u)\right\}\right]$$

We reparameterize the model, creating the parameters $\beta_i = \sigma_1^{-1}\beta_{1i}$ and $\alpha = \sigma_1^{-1}\sigma_0$. We refer to β_0 as the constant intercept, `i_cons`. The parameter α is referred to as the constant slope, `s_cons`.

$$\text{ROC}\,(u) = \Phi\{\mathbf{x}'\boldsymbol{\beta} + \alpha\Phi^{-1}\,(u)\}$$

The original model defining the classifier y leads to the following single observation likelihoods for $D = 0$ and $D = 1$:

$$L(\boldsymbol{\beta_0}, \boldsymbol{\beta_1}, \sigma_1, \sigma_0, \big| D = 0, y, \mathbf{z}, \mathbf{x}) = \frac{1}{\sqrt{2\pi}\sigma_0} \exp \frac{-(y - \mathbf{z}'\boldsymbol{\beta_0})^2}{2\sigma_0^2}$$

$$L(\boldsymbol{\beta_0}, \boldsymbol{\beta_1}, \sigma_1, \sigma_0, \big| D = 1, y, \mathbf{z}, \mathbf{x}) = \frac{1}{\sqrt{2\pi}\sigma_1} \exp \frac{-(y - \mathbf{z}'\boldsymbol{\beta_0} - \mathbf{x}'\boldsymbol{\beta_1})^2}{2\sigma_1^2}$$

These can be combined to yield the observation-level log likelihood:

$$\begin{aligned} \ln L(\boldsymbol{\beta_0}, \boldsymbol{\beta_1}, \sigma_1, \sigma_0, \big| D, y, \mathbf{z}, \mathbf{x}) = & -\frac{\ln 2\pi}{2} \\ & - I(D = 0) \left\{ \ln\sigma_0 + \frac{(y - \mathbf{z}'\boldsymbol{\beta_0})^2}{2\sigma_0^2} \right\} \\ & - I(D = 1) \left\{ \ln\sigma_1 + \frac{(y - \mathbf{z}'\boldsymbol{\beta_0} - \mathbf{x}'\boldsymbol{\beta_1})^2}{2\sigma_1^2} \right\} \end{aligned}$$

When there are multiple classifiers, each classifier is fit separately with maximum likelihood. Then the results are combined by stacking the scores and using the sandwich variance estimator. For more information, see [R] **suest** and the references White (1982); Rogers (1993); and White (1996).

Acknowledgments

We thank Margaret S. Pepe, Holly Janes, and Gary Longton of the Fred Hutchinson Cancer Research Center for providing the inspiration for the `rocreg` command and for illuminating many useful datasets for its documentation.

Title

rocreg postestimation — Postestimation tools for rocreg

Description

The following commands are of special interest after `rocreg`:

Command	Description
`estat nproc`	nonparametric ROC curve estimation, keeping fit information from `rocreg`
`rocregplot`	plot marginal and covariate-specific ROC curves

For information about `estat nproc`, see below.
For information about `rocregplot`, see [R] **rocregplot**.

The following standard postestimation commands are also available:

Command	Description
`estimates`	cataloging estimation results
`lincom`	point estimates, standard errors, testing, and inference for linear combinations
`nlcom`	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
`predict`	predictions for parametric ROC curve estimation
`test`	Wald tests of simple and composite linear hypotheses
`testnl`	Wald tests of nonlinear hypotheses

See the corresponding entries in the *Base Reference Manual* for details.

Special-interest postestimation command

The `estat nproc` command allows calculation of all the ROC curve summary statistics for covariate-specific ROC curves, as well as for a nonparametric ROC estimation. Under nonparametric estimation, a single ROC curve is estimated by `rocreg`. Covariates can affect this estimation, but there are no separate covariate-specific ROC curves. Thus the input arguments for `estat nproc` are taken in the command line rather than from the data as variable values.

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

statistic	Description
Main	
`at(`*varname*`)`	input variable for statistic
`auc`	total area under the ROC curve; the default
`roc`	ROC values for given false-positive rates in `at()`
`invroc`	false-positive rate for given ROC values in `at()`
`pauc`	partial area under the ROC curve up to each false-positive rate in `at()`
`classvar(`*varname*`)`	statistic for given classifier

options	Description
Options	
`intpts(#)`	points in numeric integration of pAUC calculation
`se(`*newvar*`)`	predict standard errors
`ci(`*stubname*`)`	produce confidence intervals, stored as variables with prefix *stubname* and suffixes `_l` and `_u`
`level(#)`	set confidence level; default is `level(95)`
* `bfile(`*filename*`, ...)`	load dataset containing bootstrap replicates from `rocreg`
* `btype(n | p | bc)`	produce normal-based (`n`), percentile (`p`), or bias-corrected (`bc`) confidence intervals; default is `btype(n)`

* `bfile()` and `btype()` are only allowed with parametric analysis using bootstrap inference.

Menu

Statistics > Postestimation > Predictions, residuals, etc.

Options for predict

Main

`at(`*varname*`)` records the variable to be used as input for the above predictions.

`auc` predicts the total area under the ROC curve defined by the covariate values in the data. This is the default statistic.

`roc` predicts the ROC values for false-positive rates stored in *varname* specified in `at()`.

`invroc` predicts the false-positive rates for given ROC values stored in *varname* specified in `at()`.

`pauc` predicts the partial area under the ROC curve up to each false-positive rate stored in *varname* specified in `at()`.

`classvar(`*varname*`)` performs the prediction for the specified classifier.

Options

`intpts(#)` specifies that # points be used in the pAUC calculation.

`se(`*newvar*`)` specifies that standard errors be produced and stored in *newvar*.

`ci(`*stubname*`)` requests that confidence intervals be produced and the lower and upper bounds be stored in *stubname*`_l` and *stubname*`_u`, respectively.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.7 Specifying the width of confidence intervals**.

`bfile(`*filename*`, ...)` uses bootstrap replicates of parameters from `rocreg` stored in *filename* to estimate standard errors and confidence intervals of predictions.

`btype(n | p | bc)` specifies whether to produce normal-based (`n`), percentile (`p`), or bias-corrected (`bc`) confidence intervals. The default is `btype(n)`.

Syntax for estat nproc

```
estat nproc [ , estat_nproc_options ]
```

estat_nproc_options	Description
Main	
`auc`	estimate total area under the ROC curve
`roc(`*numlist*`)`	estimate ROC values for given false-positive rates
`invroc(`*numlist*`)`	estimate false-positive rate for given ROC values
`pauc(`*numlist*`)`	estimate partial area under the ROC curve up to each false-positive rate

At least one option must be specified.

Menu

Statistics > Postestimation > Reports and statistics

Options for estat nproc

Main

`auc` estimates the total area under the ROC curve.

`roc(`*numlist*`)` estimates the ROC for each of the false-positive rates in *numlist*. The values in *numlist* must be in the range (0,1).

`invroc(`*numlist*`)` estimates the false-positive rate for each of the ROC values in *numlist*. The values in *numlist* must be in the range (0,1).

`pauc(`*numlist*`)` estimates the partial area under the ROC curve up to each false-positive rate in *numlist*. The values in *numlist* must be in the range (0,1].

Remarks

Remarks are presented under the following headings:

Using predict after rocreg
Using estat nproc

Using predict after rocreg

`predict`, after parametric `rocreg`, predicts the AUC, the ROC value, the false-positive rate (invROC), or the pAUC value. The default is `auc`.
